SOOHYUN CHO (Presenter), Yonsei University, SEUNG RYONG PARK, Incheon National University — We investigate the hidden Berry curvature in bulk 2H-WSe_2 by utilizing the surface sensitivity of angle resolved photoemission (ARPES). The symmetry in the electronic structure of transition metal dichalcogenides is used to uniquely determine the local orbital angular momentum (OAM) contribution to the circular dichroism (CD) in ARPES. The extracted CD signals for the K and K' valleys are almost identical, but their signs, which should be determined by the valley index, are opposite. In addition, the sign is found to be the same for the two spin-split bands, indicating that it is independent of spin state. These observed CD behaviors are what are expected from Berry curvature of a monolayer of WSe_2. In order to see if CD-ARPES is indeed representative of hidden Berry curvature within a layer, we use tight binding analysis as well as density functional calculation to calculate the Berry curvature and local OAM of a monolayer WSe_2. We find that measured CD-ARPES is approximately proportional to the calculated Berry curvature as well as local OAM, further supporting our interpretation.
9:12AM F27.00007: Theoretical study on symmetries and properties of three-dimensional valleytronic systems  MANABU TAKEICHI (Presenter), SHUICHI MURAKAMI, Tokyo Inst of Tech - Tokyo — Materials with spin-split valleys showing direct bandgaps, such as transition metal dichalcogenides, have been attracting interest in the context of valleytronics. All such materials known so far are two-dimensional. In this talk, we show a list of space groups to realize three-dimensional materials with such a valley degree of freedom. For this purpose, we made some criteria for space groups allowing valleys with good properties for valleytronics, and we find that there are only a few space groups that satisfy all of these criteria. Moreover, we propose a model which possesses inequivalent six valleys, and reveal its properties in the context of valleytronics, such as spin-valley coupling, nonzero Berry curvature, and some ways of controlling these valleys.

9:24AM F27.00008: Atomic and Electronic Structure of the Edges of multilayer and Monolayer Tin disulfide (SnS$_2$)  TAO YAN (Presenter), Materials Science and Engineering, Worcester Polytechnic Institut — Because of its two-dimensional structure and semiconducting properties, tin disulfide (SnS$_2$) is of interest for applications in electrochemical catalysis and sensing, as an electron transport layer for photovoltaics, and as an active material in photodetectors and thin film transistors. While the atomic and electronic structure of the basal planes of bulk and monolayer SnS$_2$ are well known, the same is not known for the edges, which could have a major influence on the performance of SnS$_2$ in the aforementioned applications. This paper reports on density functional theory (DFT) simulations and experimental measurements of the atomic and electronic structure of the edges of multilayer and monolayer SnS$_2$ under different chemical conditions. We found that the band gap of the SnS$_2$ edges becomes smaller with increasing sulfur coverage, and thereby determined the influence of chemical synthesis conditions on the electronic structure of the edges. We also found that as-synthesized SnS$_2$ has unpaired electrons at the edges, which suggests a direction to solve the degradation issue of SnS$_2$ as a catalyst in aqueous electrolytes.
9:36AM F27.00009: Theoretical and experimental measurements for the \((\text{Eu}_{1-x} \text{Sc}_x)^2 \text{Zr}_2 \text{O}_7\)

**Zirconate pyrochlore**

MOURAD BOUJNAH (Presenter), Institute of Materials Research - UNAM —

The interest to study pyrochlores was the diver’s optical, electric and magnetic properties. Theoretical work was done by using density functional theory (DFT). We studied the electronic properties to see the effect of Scandium in \(\text{Eu}_2 \text{Zr}_2 \text{O}_7\) for several percentage of Sc doping in the Zirconate pyrochlore and we see that we shift from half metal with an important magnetic moment to predicting semiconductor with 2.8 eV as band gap. Moreover, we observed that these doping present a significant coefficient absorption and transmission in the visible range which are around \(10 \times 10^4 \text{ cm}^{-1}\) and 88 % respectively. To understand that we calculated the electrical properties. For the experimental results, when \(x = (0, 0.5 \text{ and } 1)\) we observed by thermal analysis an interesting behavior in air. Generally gone mass and exhibits exothermic and endothermic conduct. Each thermal change, it is analysed with X-ray powder diffraction also the reagents. We detected a substitutional solid solution with complex mechanism, in air and oxygen flux.

Summary, \(\text{ZrO}\) unit cell accept oxygen and exist cationic substitution in \(\text{Sc}\) and \(\text{Eu}\) ions.

*No specific funding for this work*

9:48AM F27.00010: ACCURATE, SELF – CONSISTENT DENSITY FUNCTIONAL THEORY

**DESCRIPTION OF ROCK-SALT MAGNESIUM SELENIDE (MgSe)**

BLAISE AYIRIZIA (Presenter), UTTAM BHANDARI, YURIY MALOZOVSKY, LASHOUNDA T FRANKLIN, DIOLA BAGAYOKO, Southern Univ & A&M Coll — We report comprehensive results from density functional theory (DFT) calculations of electronic, transport, and bulk properties of magnesium selenide (MgSe) in the rock-salt crystal structure. We used a local density approximation (LDA) potential and the linear combination of atomic orbitals (LCAO) method. We performed a generalized minimization of the energy using successive, self-consistent calculations with augmented basis sets. We verifiably attain the ground state of the material. Therefore, our results possess the full physical content of DFT. With a room temperature lattice constant of 5.460Å, our calculated, indirect band gap is 2.49 eV. We present the ground state band structure and the total (DOS) and partial (pDOS) densities of states. Our results are practically in agreement with available, corresponding experimental data and with some previous, theoretical findings. We found a value of 63.1GPa for the bulk modulus, in excellent agreement with the experimentally determined 62.8 ±1.6 GPa.

*This work was funded in part by the US Department of Energy – National, Nuclear Security Administration (NNSA) (Award No. DE- NA0003679), the National Science Foundation (NSF) (Award No. HRD-1503226), LaSPACE, and LONI-SUBR.*
10:00AM F27.00011: First principle investigation of electronic, transport, and bulk properties of zinc-blende magnesium sulfide (MgS)*

**UTTAM BHANDARI (Presenter), BLAISE AYIRIZIA, YURIY MALOZOVSKY, LASHOUNDA T FRANKLIN, DIOLA BAGAYOKO, Southern Univ & A&M Coll** — We have studied the electronic, structural, and transport properties of the zinc-blende magnesium sulfide (zb-MgS), using Density Functional Theory (DFT). We employed a Local Density Approximation (LDA) potential with a Linear Combination of Atomic Orbitals (LCAO) approach. Our computational method leads to the ground state of the materials without utilizing over-complete basis sets. The calculated direct band gap of zb-MgS is 4.43 eV, in excellent agreement with the experimental band gap of 4.45 ± 0.2 eV. We also report the total and partial densities of states, the electron effective masses, the equilibrium lattice constant, and the bulk modulus.

*Work funded in part by the US Department of Energy (DOE), National Nuclear Security Administration (NNSA) (Award No.DE-NA0003679), the National Science Foundation (NSF) (Award No, 1503226), LaSPACE, and LONI-SUBR.

10:12AM F27.00012: Towards a Th-229 Nuclear Clock: Measurements of the Bandgap of ThF$_4$ by Electron Spectroscopy Techniques

**ROBERTO CACIUFFO (Presenter), THOMAS GOUDER, RACHEL ELOIRDI, Joint Research Centre, European Commission, Karlsruhe (Germany), MIKHAIL OSIPENKO, Istituto Nazionale Fisica Nucleare, Genova, Italy, MAURO GIOVANNINI, Department of Chemistry, University of Genova, Italy, RICHARD L. MARTIN, Theoretical Division, Los Alamos National Laboratory, NM** — The existence of an excited nuclear state at about 8.3 eV in Th-229 has stimulated enormous interest, because it opens the possibility to develop solid-state optical nuclear clocks with unparalleled accuracy and stability. In such a device, Th-229 should be embedded in a crystalline matrix with a band gap larger than the isomer energy, in order to suppress decay by internal conversion. The crystal matrix should also be able to host Th-229 atoms in regular lattice positions, in order to minimize color center defects. Here, we present an experimental determination of the bandgap of ThF$_4$ performed by two different techniques. The first one is based on a combination of x-ray photoemission spectroscopy and bremsstrahlung isochromat spectroscopy. The second measurement exploited the position of the inelastic threshold in reflection electron energy loss spectroscopy. Both measurements gave compatible values of the bandgap, with the average $\Delta E = 10.2(2)$ eV [1]. This value is in excellent agreement with theoretical calculations. The measured bandgap is significantly larger than the $^{229}\text{m}^\text{Th}$ excitation energy making ThF$_4$ a possible candidate material for a solid-state nuclear clock based on the vacuum ultraviolet $\gamma$ decay.

10:24AM F27.00013: Analysis of pre-edge of oxygen K-edge X-ray absorption spectra of transition metal oxides*  RUIMIN QIAO, SUBHAYAN ROYCHOUDHURY (Presenter), DAVID PRENDERGAST, WANLI YANG, Lawrence Berkeley National Laboratory — The recently developed MBXAS[1] formalism is a powerful tool for inexpensive, accurate simulation of X-ray absorption spectroscopy (XAS). By approximating the final (initial) many-body state as a Slater determinant of all electronic orbitals obtained in presence (absence) of the core hole, one can accurately simulate the electronic relaxation resulting from core-excitation, while maintaining computational advantage by staying within a mean-field framework, such as density functional theory (DFT). In collaboration with experimentalists, we used MBXAS to simulate the oxygen-K edge XAS of 3-d transition metal oxides (TMO). The onset-energy of each spectrum is determined from total energy differences of ground and excited state DFT calculations. For a given transition-metal, the first O K-edge pre-peak energy decreases with increasing valence, indicating strong contribution of metal 3-d levels in the conduction band edge via hybridization. Unlike transition-metal L-edge spectra, which are dominated by local atomic ligand field effects, the O K-edge essentially maps the conduction bands. The oxygen-K edge offers us an opportunity to plot the first-peak positions of all TMOs with a common energy scale.

*Research supported by LDRD funding from Berkeley Lab.

10:36AM F27.00014: A detailed Raman study of the photochemical oxidation process of monolayer CVD grown graphene  MOHD MUSAIB HAIDARI (Presenter), JIN HONG KIM, JIN SIK CHOI, KonKuk Univ — Although graphene oxide (GO) has emerged as a promising material in the semiconductor industry, optimization of oxidation conditions to meet industrial needs had remained a challenge for researchers. We prepared a monolayer GO sheet by photochemical treatment of CVD graphene within 80 s using UV irradiation. TEM data confirms that there were no structural defects through the optimized oxidation condition with 20% oxygen content. Comparing to conventional GO flakes, this large area GO layer shows higher homogeneity in functional group distribution. Comparison of Amplitude and Area intensity ratios of Raman peaks and XPS data show a correlation between changes in D’ (~1620 cm−1), G (~1587 cm−1), and 2D (~2678 cm−1) peaks with C sp3 (C-O), epoxide (C-O-C), and C sp2 (C=C) bonding. Moreover, although patterned graphene and GO regions are imperceptible by optical illuminance, they are distinguishable by Raman D and/or G-peak mapping. According to AFM data, our GO samples show the average thickness of 0.79 nm in its optimized condition with an ultra-clean surface comparable to that of exfoliated graphene. This work reveals some details about the oxidation process of graphene and sets the ground for transparent flexible optical and electrical applications of functionalized graphene.
10:48AM F27.00015: Realization of BaZrS$_3$ chalcogenide perovskite thin films for optoelectronics

**XIUCHENG WEI** (Presenter), HAOLEI HUI, State University of New York at Buffalo, MENGJIAO HAN, Southern University of Science & Technology, Shenzhen, SAMANTHE PERERA, University of Science and Arts of Oklahoma, JUNHAO LIN, Southern University of Science & Technology, Shenzhen, YI-YANG SUN, Shanghai Institute of Ceramics, Chinese Academy of Sciences, SHENGBAI ZHANG, Rensselaer Polytechnic Institute, HAO ZENG, State University of New York at Buffalo — BaZrS$_3$, a prototypical chalcogenide perovskite, has not yet been deeply explored despite being first synthesized in the mid-1950s. In recent years, several publications on powder samples reveal that BaZrS$_3$ has a direct band gap of 1.7 to 1.8 eV, a high stability against moisture and pressure, and a very strong interaction with light. However, many of the fundamental properties still remain unknown due to the lack of film samples. Here we report the fabrication of BaZrS$_3$ thin films, by sulfurization of corresponding BaZrO$_3$ films deposited by pulsed laser deposition. Transport measurements indicate the films are n-type semiconductors with carrier densities in the range of $10^{19}$ to $10^{20}$ cm$^{-3}$. The hall mobility ranges from 2.1 to 13.7 cm$^2$/Vs depending on the sulfurization temperature. UV-Vis result shows an absorption coefficient of $>10^5$ cm$^{-1}$ at a photon energy of $>1.97$eV and temperature dependent conductivity measurements reveal shallow donor level with an activation energy of several milli-electron volts. Our results assure that BaZrS$_3$ is a promising candidate material for optoelectronics.

Session F28 FIAP FECS: Seeing Your Career In a New Light 405-407 - Benjamin Ueland, Ames Lab - Tag(s): Careers, Industry, Invited, Undergrad Friendly

8:00AM F28.00001: Life as a PhD/MBA in the Optics and Photonics Industry [Invited] YURI SIKORSKI (Presenter), Excelitas Technologies Corp. — TBD

8:36AM F28.00002: When your protagonist is a Hamiltonian: A career in physics writing and editing [Invited] JESSICA THOMAS (Presenter), American Physical Society — Physics (physics.aps.org) is the online magazine for the Physical Review journals. We write and edit articles about top papers from the journals; we also work on news features, Q&As, and a variety of stories related to physics research and its influences. This talk is aimed at anyone who wants to learn more about a career in science writing and editing. Using a few examples of recent Physics articles, I'll give you an inside look at what we do and where we get our ideas. I'll also explain how the members of our team broke into this line of work and the skills we seek when hiring.

9:12AM F28.00003: From the Study of Physics to Entrepreneurship [Invited] JERAMY HUGHES (Presenter), FieldLine Inc. — Sit back as I take you on a journey that starts with working in the labs of Nobel Laureates and continues with founding FieldLine, a company that is creating world changing medical technologies. There will be plenty of failure, restarts, and advice for success as you learn how you can make the most of your opportunities.
9:48AM F28.00004: Navigating a National Lab Career [Invited]  JOHN SARRAO (Presenter), Los Alamos Natl Lab — The Department of Energy’s seventeen National Laboratories provide a career path that’s in between academia and industry. And the National Labs are hiring, with a number of Labs having hiring needs that are greater than 1000 staff/year. Nevertheless, the National Labs are relatively unknown to many students (and faculty) in academia. In this presentation, an overview of the Department of Energy National Laboratories is provided as well as a description of possible trajectories that span from graduate student for the duration of one’s career (as in the case of the speaker) to a variety of short-term internships, post-doc appointments, and staff positions.

10:24AM F28.00005: Trailblazing an Industrial Physics Career: Three Case Studies on Getting Hired Outside Your Subfield [Invited]  MATTHEW THOMPSON (Presenter), BAE Systems — You have probably heard that physicists are very employable and most of us find positions in the private sector. That is great news but making the transition can seem daunting when you are wrapping up your academic research on a hyper-specific topic in a narrow specialty. In this talk, I will recount how I switched subfields three times since leaving graduate school along with the lessons I learned about succeeding in the job market along the way. Moving between areas as diverse as particle accelerator physics, magnetic confinement fusion, and aerospace has been a fascinating journey I look forward to sharing.

Tuesday, March 3, 2020 8:00 AM - 10:48 AM

Session F29 DSOFT DBIO DFD GSNP: Active Matter in Complex Environments IV  501 - Tapomoy Bhattacharjee, Princeton University

8:00AM F29.00001: Nonequilibrium phases in mixtures of active and passive particles  JUNANG LI (Presenter), SHREYAS GOKHALE, Massachusetts Institute of Technology MIT, ALEXANDRE SOLON, Physics, Sorbonne Université, JEFFREY GORE, NIKTA FAKHRI, Massachusetts Institute of Technology MIT — Active systems composed of self-propelled particles are intrinsically out of equilibrium. Due to the breaking of detailed balance at the individual particle level, they exhibit complex dynamic phenomena not observed in their equilibrium counterparts. For instance, distinct nonequilibrium phases such as a demixed state and motility induced phase separated state (MIPS) can arise in a binary mixture of passive and active particles. Here, we map the computational phase diagram of a binary mixture of active and passive particles as a function of orientational interactions and Peclet number and observe new emergent behavior of dynamical clustering and a polar band of active particles. This computational study helps us to illuminate observations of experiments we developed consisting of passive colloid particles immersed in a bath of bacteria. By quantifying fluctuations and correlations between passive particles in both simulations and experiments, we quantify how far the system is from equilibrium.
8:12AM F29.00002: Tuning the self-organization of confined active particles by the steepness of the trap  SHUBHASHIS RANA (Presenter), Univ of Houston, MD. SAMSUZZAMAN, ARNAB SAHA, Physics, Savitribai Phule Pune University — We consider the collective dynamics of self-propelling particles in two dimensions. They can align themselves according to the direction of propulsion of their neighbours, together with small rotational fluctuations. They also interact with each other via soft, isotropic, repulsive potentials. The particles are confined in a circular trap. The steepness of the trap is tuneable. The average packing fraction of the particles is low. When the trap is steep, particles flock along its boundary. They form a polar cluster that spreads over the boundary. The cluster is not spatially ordered. We show that when the steepness is decreased beyond a threshold value, the cluster becomes round and compact and eventually spatial order (hexagonal) emerges in addition to the pre-established polar order. We investigate the kinetics of such ordering. We find that while rotating around the centre of the trap along its circular boundary, the cluster needs to roll around its centre of mass to be spatially ordered. We have studied the stability of the order when the trap is suddenly switched off. We find that for the particles with velocity alignment interaction, the decay of the spatial order is much slower than the particles without the alignment interaction.

8:24AM F29.00003: Active matters: broken symmetries and response  SARA DAL CENGIO (Presenter), DEMIAN LEVIS, Univ de Barcelona, IGNACIO PAGONABARRAGA, EPFL — We address the question of how interacting active systems in a non-equilibrium steady-state respond to an external perturbation. We establish an extended fluctuation-dissipation theorem for Active Brownian Particles (ABP) which highlights the role played by the local violation of detailed balance due to activity. By making use of a Markovian approximation we derive closed Green-Kubo expressions for the diffusivity and mobility of ABP and quantify the deviations from the Stokes-Einstein relation. We compute the linear response function to an external force using unperturbed simulations of ABP and compare the results with the analytical predictions of the transport coefficients. Our results show the importance of the interplay between activity and interactions in the departure from equilibrium linear response.

8:36AM F29.00004: Spontaneous symmetry breaking induced unidirectional rotation of a chain-grafted colloidal particle in the active bath*  WENDE TIAN (Presenter), Soochow Univ — Exploiting the energy of randomly moving active agents such as bacteria is a fascinating way to power a microdevice. Here we show, by simulations, that a chain-grafted disk-like colloidal particle can rotate unidirectionally and hence output work when immersed in a thin film of active particle suspension. The collective spontaneous symmetry breaking of chain configurations is the origin of the unidirectional rotation. Long persistence time, large propelling force and/or small rotating friction are keys to sustaining the collective broken symmetry and realizing the rotation. In the rotating state, we find very simple linear relations, e.g. between the mean angular speed and the propelling force. The time-evolving asymmetry of chain configurations reveals that there are two types of non-rotating state. The basic phenomena are also observed in the macroscopic granular experiments, implying the generic nature of these phenomena. Our findings provide new insights into the collective spontaneous symmetry breaking in active systems with flexible objects and also open the way to conceive new soft/deformable microdevices.

8:48AM F29.00005: Temperature dependence of microtubule-based active fluid  TEAGAN BATE (Presenter), EDWARD J JARVIS, MEGAN VARNEY, KUN-TA WU, Worcester Polytech Inst — Kinesin molecular motors step along microtubules in cells to transport cargos with a stepping speed that increases with temperature. This temperature-dependent speed was reported to follow the Arrhenius Law. Kinesin was also used to drive microtubule-based active fluid; however, whether the flow of the fluid follows the Arrhenius Law to accelerate with temperature remains unclear. Here, we systematically characterized the flow speed of kinesin-driven active fluid as a function of temperature, followed by fitting the data to the Arrhenius equation. We characterized the temperature dependence of the flow speed in three different motor systems: (1) processive motors, (2) non-processive motors, and (3) an even mixture of both, finding that these systems followed the Arrhenius Law and developed faster flows with increasing temperature. However, we found that the relation between the flow speed and temperature could be reversed by introducing a depleting agent that had a temperature-dependent micelle formation, causing the active fluid to flow more slowly when heated. Finally, we heated and cooled the fluid repeatedly to accelerate and decelerate the flow sequentially, demonstrating the ability to control the flow speed in real time.

9:00AM F29.00006: Elasticity mediated attraction between active polar particles*  RAHUL GUPTA (Presenter), TIFR Centre for Interdisciplinary Sciences, RAUSHAN KANT, HARSH SONI, AJAY SOOD, SRIRAM RAMASWAMY, Physical Sciences, Indian Institute of Science — We investigate in experiments and simulations the interaction between a pair of motile granular rods moving through a dense monolayer of beads. Vibration of the supporting surface provides the energy source for motility. Above a critical value of the bead area fraction we find that the rods reorient in such a way as to be drawn towards each other. We present a theory for this active attraction based on the forcing imposed by the motile rods on the crystalline medium of beads, and the action of the medium on the rod orientation. Our theoretically calculated the displacement field around a single rod compares favourably with measurements in simulations. We also discuss the segregation instability for the case of many rods.

*SR was supported by SERB (India) and the Tata Education and Development Trust
9:12AM F29.00007: Light-regulated swimming motility induces cell aggregation in confinement
ALEXANDROS FRAGKOPOULOS (Presenter), JÉRÉMY VACHIER, JOHANNES FREY, FLORA-MAUD LE MENN, MICHAEL WILCZEK, Department of Dynamics of Complex Fluids, Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany, MARCO G. MAZZA, Department of Mathematical Sciences, Loughborough University, Leicestershire LE11 3TU, United Kingdom, OLIVER BAEUMCHEN, Department of Dynamics of Complex Fluids, Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany — A highly concentrated suspension of self-propelled particles can form large-scale concentration patterns, separating into regions of high and low particle concentrations. This phenomenon is induced by the activity of the particles and mediated by their mutual interactions. We observe that a suspension of freely swimming Chlamydomonas reinhardtii cells, a unicellular soil-dwelling microalgae and a model organism of puller-type microswimmers, forms such large-scale aggregations under confinement in specific light conditions. We find that the cell's motility changes under different light conditions. Through active Brownian particle simulations, we show that the change of the motility is sufficient to regulate cell aggregation. Finally, we show evidence that the extent of the photosynthetic activity controls the cell's motility, and consequently, the aggregation formation.

9:24AM F29.00008: Undulatory intruder dynamics in water-saturated granular beds*
ARSHAD KUDROLLI (Presenter), TRINH HUYNH, Clark University — We will report an investigation of active intruder dynamics through complex media with Lumbriculus variegatus moving through water saturated granular beds which are refractive index matched to enable observation of their motion inside the bed. These common marsh and pond dwelling worms display dual longitudinal peristaltic and transverse undulatory strokes. We will demonstrate that only the undulatory stroke plays a role in locomotion while swimming in water and in very shallow sediment layers which do not permit anchoring. The greater drag anisotropy of the rod like body in the sediments is shown to enable faster locomotion speeds compared to water because of drag-assisted propulsion. By constructing a magnetically driven soft filament robot, we will then describe the observed speeds as a function of undulatory strokes under prescribed conditions which include the undulation frequency and amplitude and the rheology of the medium.

*Supported by NSF Grant CBET-1805398.
9:36AM F29.00009: Pressure of bacterial suspensions on confining walls and freely moving chains

XIAOLEI MA (Presenter), SHUO GUO, Department of Chemical Engineering and Materials Science, University of Minnesota, XINLIANG XU, Complex Systems Division, Beijing Computational Science Research Center, XIANG CHENG, Department of Chemical Engineering and Materials Science, University of Minnesota — An active matter consists of a large number of self-propelling units capable of taking in, employing and dissipating energies. Different from equilibrium systems with detailed balance, active matter exhibits many unusual properties, highlighting the nonequilibrium nature of the system. In particular, mechanical pressure, a state variable in equilibrium systems, shows a nontrivial dependence on system boundary as well as specific measurement methods. Here, we experimentally study the mechanical pressure of bacterial suspensions by exploring the interactions between swimming Escherichia coli and confining walls of different shapes, as well as flexible chains of colloids linked by DNA in a quasi-two-dimensional space. We find that the pressure exerted by *E. coli* depends nonmonotonically on the apex angle of the V-shaped confining walls. We further characterize the interactions between *E. coli* and the freely-moving particle chains via imaging the fluctuation of the configuration of the particles and explore their dependence on the rigidity and the length of the chains. A hydrodynamic model is finally proposed to explain our results. Our study sheds light onto the mechanical properties of active matter and provides new understanding on the pressure exerted by swimming microorganisms.

9:48AM F29.00010: Active surfers on a vibrating bath: self-propulsion and interactions

ANAND OZA (Presenter), New Jersey Inst of Tech, IAN HO, School of Engineering, Brown University, GIUSEPPE PUCCI, Institut de Physique de Rennes, DANIEL M HARRIS, School of Engineering, Brown University — We present a combined experimental and theoretical investigation of a newly discovered active matter system consisting of objects floating on a vertically vibrating fluid bath. Recent experiments have demonstrated that such "surfers" oscillate vertically while self-propelling at constant horizontal velocity on the fluid interface. Multiple surfers may self-organize through the collective interfacial deformation in the form of propagating capillary waves. The experiments are complemented by a theoretical model for the surfer's positional and orientational dynamics. The model predictions exhibit good agreement with experimentally observed interaction modes between two surfers. Generally, this work shows that self-propelling objects coupled by interfacial flows constitute a tunable platform for expanding our understanding of active systems.
10:00AM F29.00011: Nutrient depletion thresholds in 3D printed cell assemblies  CAMERON MORLEY (Presenter), THOMAS ANGELINI, University of Florida — Energy consumption is an essential part of active matter; in biological systems energy consumption is often limited by the delivery of oxygen and glucose. Within tissues, these molecules are delivered to cells by a combination of flow through vasculature and intra-tissue diffusion. For dense tissues, the rates of oxygen and glucose diffusion compete with the rates at which they are metabolized, creating a threshold distance from a blood vessel, beyond which cells will become starved. It is almost universally accepted that in tissues of living organisms and in engineered tissues, all cells must be within 200 microns of vasculature because of this competition between diffusion and consumption. However, this rule cannot apply generally to all tissues because cellular metabolic rates are highly variable across cell types and cell densities. In this talk, we will describe experiments that test the 200 micron rule in which we 3D print controlled distributions of hepatocytes into 3D culture medium made from jammed granular microgels. By monitoring cell viability and the consumption of oxygen and glucose, we identify the diffusion-limited crossover to nutrient or oxygen deprived conditions. We vary the size of 3D printed structures and the cell density within them.

10:12AM F29.00012: Control of Active Nematics through Friction*  KRISTIAN THIJSSEN (Presenter), LUUK METSELAAR, University of Oxford, TYLER N SHENDRUK, Loughborough University, AMIN DOOSTMOHAMMADI, The Niels Bohr Institute, JULIA YEOMANS, University of Oxford — Using continuum simulations, we study the impact of anisotropic friction and of position-dependent friction on the emergent flows of active nematics. We show that, depending on whether the active particles align with or tumble in their collectively self-induced flows, anisotropic friction can result in markedly different patterns of motion. For a flow-aligning system with high anisotropic friction, the otherwise chaotic flows are streamlined into flow lanes, reproducing the experimental laning state, which has been obtained by interfacing microtubule-motor protein mixtures with smectic liquid crystals. However, this state is not possible in the flow-tumbling regime, emphasising the role of the flow-tumbling parameter in the dynamics of active nematics. Furthermore, we show that position-dependent friction in active nematic layers allows for the control of the active flows by creating effective hydrodynamic boundaries. Our work demonstrates novel methods to control active matter without the introduction of invasive solid bounding walls.

*This project has received funding from the European Union's Horizon 2020 research and innovation programme Marie Skłodowska-Curie Grant Agreement No. 722497
10:24AM F29.00013: Inertial effects on trapped active matter* MARIO SANDOVAL-ESPINOZA (Presenter), LORENZO GUTIERREZ, Department of Physics, Universidad Autonoma Metropolitana — So far, the effect of translational and rotational inertia in the field of active matter has been almost neglected. Here, we analytically find the effect of inertia on the mean-square displacement and mean-square speed of a system of inertial active Brownian particles subject to a weak and a strong harmonic trap. To validate our analytical results, Brownian dynamics simulations are also performed showing an excellent agreement between our theoretical predictions and the numerical results.

* M. S thanks Consejo Nacional de Ciencia y Tecnologia, CONACyT Grant: CB 2014/237848 for support.

10:36AM F29.00014: Wiggling arthropods induce flow in granular materials* MELIA KENDALL, SHIH-YUAN CHEN, KAREN DANIELS (Presenter), North Carolina State University — Just as heating a viscous fluid causes its viscosity to drop, we observe that the introduction of active particles into a passive granular material can increase its flowability. This effect can be observed, for instance, in the historical practice of aging Milbenkäse cheese in mixtures of flour and mites. In our experiments, we examine this effect by introducing flour beetle larvae (Tribolium confusum) into agricultural grains of various sizes. We measure the timescale for bulk flow via the relaxation of a sloping pile, and the timescale for particle-scale rearrangements via diffusing wave spectroscopy. We find that the macroscopic and microscopic timescales are approximately proportional; both timescales decrease as the fraction of larvae increases, but only for samples in which the grains are smaller than the larvae. For samples in which the larvae and grains are of similar size, these two timescales decouple.

Tuesday, March 3, 2020 8:00 AM - 11:00 AM

Session F30 DSOFT DPOLY DBIO: Self-Limiting Assemblies II: Programmable Assemblies 502 - Efi Efrati, Weizmann Institute of Science - Tag(s): Focus
8:00AM F30.00001: Finite-Size Colloidal Constructs Designed through Self-Assembly of Defective Colloidal Molecules*  

NISHAN PARVEZ (Presenter), MEHDI ZANJANI, Miami University — Engineering various types of structures through self-assembly of colloidal particles is a powerful approach in material design and processing. While simple colloidal building blocks provide a number of well-known structures, more complex building blocks, such as colloidal molecules, are needed to create novel structures with desired functionalities and tunable properties.

In this study, we use computational techniques to identify, investigate, and exploit self-assembly paradigms that are made possible through the use of defective colloidal molecules. Specifically, we study how defective units, which are typically missing one or two particles compared to the regular units, can be taken advantage of to build finite-size constructs that would otherwise be inaccessible. We further demonstrate different types of finite-size, self-limiting, ‘supermolecules’ that can be assembled through engineered directional interactions between defective and regular colloidal molecules. We use Molecular Dynamics (MD) simulations to study the thermodynamics and kinetics of self-assembly, and investigate the phase behavior of the resulting colloidal constructs as a function of building block particle size ratio.

8:12AM F30.00002: Self-assembly of protein-made structures  

AGNESE CURATOLO (Presenter), CARL GOODRICH, OFER KIMCHI, MICHAEL PHILLIP BRENNER, Harvard University, YANG HSIA, ZIBO CHEN, SCOTT BOYKEN, DAVID BAKER, University of Washington — Living organisms create complex protein based materials with remarkable properties. Inspired by those, one could ask if it would be possible to design protein-based materials from scratch for specific human uses, with applications ranging from medicine to biomaterials.

To achieve this goal, we need to understand and re-design the rules used by nature to encode specificity in protein interactions. Sophisticated techniques for designing proteins de novo have been developed recently in David Baker's lab. These proteins interact via designed hydrogen-bonding networks and can be used as building blocks to fabricate functional materials. The drawback is the enormous space of interactions that can be designed.

In order to explore this space and identify the interactions leading to specific mechanical properties, we need to understand the link between the protein building blocks and the target structures to assemble. Here I will present different approaches that one can take to predict the yield of protein-made structures and address the difficulties of relating statistical mechanics models and real world experiments.
8:24AM F30.00003: Programmable self-assembly of DNA origami capsids based on the principles of virus structure.  
* [Invited] SETH FRADEN (Presenter), Brandeis Univ — We provide a general and modular solution for building synthetic icosahedral shells on the scale of 100 nm, motivated by the 1962 Caspar and Klug theory of virus structure. Strategies were explored for controlling the pathways, kinetics, and the yield by which subunits arrange themselves into icosahedral symmetry. The methods of DNA origami were employed to produce accurately-designed and rigid building blocks. We created multiple large virus-like capsids and validated the structures using cryo electron microscopy and studied the capsid assembly process experimentally and with a computational model to elucidate how the kinetics and yield of target structures depends on control parameters. Our capsid building blocks represent a near-ideal manifestation of patchy particles whose geometry and interactions can be designed with sub-nanometer and kBT precision, thus achieving a long sought after goal in soft matter physics.

9:00AM F30.00004: Functionalized DNA origami shells for cargo encapsulation*  
S.ALI AGHVAMI (Presenter), Physics, Brandeis University, CHRIS SIGL, ELENA WILLNER, HENDRIK DIETZ, Physics, TUM, SETH FRADEN, Physics, Brandeis University — Inspired by the efficient design of virus particles, we develop self-assembling DNA origami icosahedral nanostructures for cargo encapsulation and delivery. Our design is based on the Casper and Klug (CK) geometric principles of virus structure. We demonstrate a robust method for self-assembly of virus like DNA origami capsids of various sizes by designing specific capsomers with programmable shape complementary lock and key interactions. The building blocks are designed and constructed according to the CK symmetry principles that dictate the minimal number of distinct bonds per capsid. These DNA nanostructures are highly modular, allowing us to successfully functionalize them for encapsulation of organic and non-organic cargo particles. We study self-assembly of capsid and encapsulation of different types of particles with TEM and electrophoretic mobility assays to elucidate different aspects of assembly pathways and encapsulation yield. These DNA origami structures are biocompatible and have highly controllable size and shape, making them candidates for biomaterial engineering purposes such as drug delivery and gene therapy.

*We acknowledge financial support from NSF MRSEC DMR-1420382.
9:12AM F30.00005: Structural and mechanical properties of nucleic acid nanotubes: A combined all-atom and coarse-grained molecular dynamics study*  
SUPRIYO NASKAR (Presenter), HIMANSHU JOSHI, MOUNIKA GOSIKA, Indian Institute of Science - Dept of Physics, BANANI CHAKRABORTY, Department of Chemical Engineering, Indian Institute of Science, NADRIAN C SEEMAN, Department of Chemistry, New York University, PRABAL K MAITI, Indian Institute of Science - Dept of Physics — In this work, we introduce a computational framework to model nucleic acid nanotubes and estimate their mechanical properties using various levels of theory. Using atomistic molecular dynamics (MD) simulations, we report the enhancement of the structural and mechanical stability of DNA nanotube (DNT) by changing the salt concentrations. The calculated persistence length ($L_p$) of the DNTs is ~1-2 μm which is an order of magnitude higher than that of a single dsDNA. DNTs have stretch modulus ($\gamma$) value in the range of ~6-8 nN. We find that, with the gradual increment of salt concentration, an increase in $L_p$ and $\gamma$ which reaffirms the structural and mechanical stability of the DNT at higher salt concentrations. We also model DNT using two widely used coarse-grain (CG) models – namely Martini and oxDNA. We compare and contrast the all-atom MD and experimental results with the results obtained using these CG models. We also propose a model of hexagonal nanotubes made of dsRNA connected by double crossover at different positions. The calculated $\gamma$ and $L_p$ of the in silico modeled RNTs are in the same range of values as in the case of DNTs. Using helicoidal parameters of individual base pairs, we explain the relative flexibility and rigidity of the RNTs having different sequences.

9:24AM F30.00006: Self-assembly of DNA origami particles into self-limited surfaces*  
DAICHI HAYAKAWA (Presenter), Physics, Brandeis University, DOUGLAS HALL, Polymer Science and Engineering, University of Massachusetts Amherst, CHRIS SIGL, Physics, Technische Universität München, GREGORY GRASON, Polymer Science and Engineering, University of Massachusetts Amherst, WILLIAM ROGERS, Physics, Brandeis University — The combination of proteins’ unique folded shapes and specific interactions enable them to self-assemble into functional, nanostructured materials, such as viral capsids and microtubules. In this talk, I will present experimental results showing that we can mimic these features using DNA origami. We devise a scheme for designing synthetic building blocks with prescribed shapes and specific interactions. Our building blocks are DNA origami triangles, which bind via DNA base stacking interactions between shape-complementary edges. The dihedral angles between neighboring building blocks can be tuned independently by designing the building-block geometry. We illustrate our design approach by making triangular building blocks that assemble into self-limited structures, like a zigzag nanotube which is limited in size along one dimension. Molecular dynamics simulations, gel electrophoresis, and electron microscopy verify the three-dimensional structures of the individual building blocks as well as their assemblies. Going forward, our design method will enable us to create other building blocks that self-assemble into surfaces with user-prescribed curvatures.

*We acknowledge financial support from NSF MRSEC DMR-1420382.
9:36AM F30.00007: Frustration in the absence of Gaussian Curvature: what we learned from colloidal crystallization on a cylinder*  NABILA TANJEEM (Presenter), WILLIAM H WILKIN, CHRISTOPHER RYCRFT, VINOTHAN MANOHARAN, Harvard University — We demonstrate the effects of a closure constraint on a crystal in the absence of Gaussian curvature. Most studies on closure constraints have focused on crystals on the surface of a sphere, in which case both Gaussian curvature and topology affect the crystallization dynamics. To separate the effects of topology from Gaussian curvature, we study crystallization of colloidal spheres on the surface of a cylinder experimentally, because a cylinder has zero Gaussian curvature, but has a surface that loops back on itself. We find that chiral structures and line-slip defects emerge owing to the closure constraint. We also find that owing to anisotropic crystal growth on a thin and long cylinder, line-slip defects with smaller chiral angles become frustrated, incorporating kinks and fractional vacancies that do not relax in experimental timescale. We show a connection between crystal morphology and growth dynamics, which may elucidate the assembly mechanism of tubular crystalline materials, such as rod-like viruses, bacterial S-layers, and nanotubes.

*This work was supported by Harvard MRSEC (NSF DMR 1420570).

9:48AM F30.00008: Self-Assembly of Triply-Periodic Minimal Surfaces, An “Inverted” Caspar-Klug Approach*  CARLOS DUQUE (Presenter), DOUGLAS HALL, Univ of Mass - Amherst, BOTOND TYUKODI, MICHAEL HAGAN, Physics, Brandeis University, GREGORY GRASON, Univ of Mass - Amherst, CHRISTIAN SANTANGELO, Physics, Syracuse University — The seminal work of Caspar and Klug paved the way to deepen our understanding of the formation of viral shells. Since then, many efforts have been put into understanding the structural properties of a wide variety of viruses. Recently, with the development of DNA nanotechnology, it has been possible to program DNA nanoparticles to self-assemble into intricate shapes by carefully designing some elemental building blocks. In this work, we are interested in studying an “inverted” Caspar-Klug problem, focussed primarily on structures with negative Gaussian curvature. More specifically, we study a family of surfaces called triply periodic minimal surfaces (TPMS). During this talk I'll describe our efforts to discretize these surfaces using a Caspar-Klug approach. Furthermore, I’ll discuss how we can encode some simple rules on the programable matter in order to self-assemble into the desired structures. We perform Monte Carlo simulations to test the validity of the matching rules and finally touch upon the robustness of the assembled structures with the introduction of imperfections in the assembly process.

*NSF grant DMR-1507377
10:00 AM F30.00009: Colloidal crystallization on a cone* JESSICA SUN (Presenter), NABILA TANJEEM, VINOTHAN MANOHARAN, Harvard University — We study the self-assembly of colloidal spheres on the surface of a cone, which has zero Gaussian curvature but varying mean curvature. Therefore, we expect that a colloidal crystal growing on a cone must self-intersect at an angle and is limited to a finite size. In our experimental system, colloidal particles assemble by short-ranged depletion interactions onto a pulled microcapillary tube. For a cylindrical tube of constant mean curvature, defects form where the crystalline grain self-intersects. These defects, called line-slip defects, consist of particle pairs with five-fold coordination along the defect line. However, as we increase the cone angle of the tube, a gap opens up along the defect line. This gap, or fractional vacancy, has varying width along the length of the defect. We show that the varying width of the fractional vacancy corresponds with the cone angle. When we increase the cone angle to a critical value, the system reaches a jammed state.

10:12 AM F30.00010: Programming extrinsic geometry to control membrane self-assembly* DOUGLAS HALL (Presenter), Univ of Mass - Amherst, MARK STEVENS, Sandia National Laboratories, GREGORY GRASON, Univ of Mass - Amherst — Advancements in nanotechnology have furthered the ability for tailoring shape of building blocks for self-assembly. A current challenge is to develop theories of self-limiting assembly of distinct superstructures, e.g. to create ribbons with robustly self-regulating and finite dimensions that are much larger than the building block dimensions. Previous work successfully describes helical nanoribbon assembly and how molecular shape is related to the programmed intrinsic geometry of the assembly (i.e. the preferred Gaussian curvature), resulting in self-limitation via frustration-induced stresses.

In this talk, we show how an additional molecular shape parameter separately controls the extrinsic geometry (i.e. the directionality of curvature axis relative to inter-block packing directions), modulates the intrinsic frustration energetics and influences the size scale over which frustration stress accumulate in the assembly. We derive a continuum elastic description of intrinsic- and extrinsic-programmed membranes, relate it to a coarse-grained model that realizes these shape parameters and verify the role of extrinsic geometry with simulations.

*We acknowledge NSF DMR-1608862, NSF MRSEC DMR-1420382 and the DOE CINT User facility.
10:24AM F30.00011: Dynamical and equilibrium calculations of self-limited assembly through geometric frustration*  BOTOND TYUKODI (Presenter), FARZANEH MOHAJERANI, Brandeis University, GREGORY GRASON, UMass Amherst, MICHAEL HAGAN, Brandeis University — The self-assembly of subunits into large structures with well-defined finite sizes is ubiquitous in biology. Understanding how to engineer self-assembling structures that exhibit such self-limiting assembly would have important applications in developing functional materials. Recent theoretical arguments have proposed a broad mechanism for self-limiting, geometrically frustrated assembly, in which the preferred local packing of subunits is frustrated by an incompatibility with the preferred global order of the assembly process.

In this talk, we use a recently developed dynamical MC algorithm and free energy calculations to study the assembly of subunits that undergo frustrated assembly. We consider triangular elastic subunits that assemble into a 2D sheet with local hexagonal packing, which is frustrated by the fact that the preferred inter-subunit binding angle favors a negative Gaussian curvature. This incompatibility induces a strain which grows with the size of the assemblage, in some cases leading to a finite size equilibrium assembly with open boundaries. We characterize the relationship between subunit geometry, material properties, the assembly size, and its robustness to parameter variations.

10:36AM F30.00012: Emergence of fiber in frustrated self assembly  HUGO LE ROY (Presenter), MARTIN Lenz, MERT TERZI, University of Paris Sud — Self-organization is an essential characteristic of life at all scales. Mistakes in self-organization at the protein level can lead to severe diseases such as Alzheimer’s, in which normally soluble proteins aggregate into fibril structures that interfere with the protein’s initial biological role. We try to understand the general mechanism behind these aggregation phenomena, which are exhibited by a wide variety of proteins. If surface tension energy would drive aggregation, it would do so at the cost of elastic energy due to protein deformation from there ill-fitting shape. Previous studies have found that fiber-like aggregates can have an energetic benefit over other shapes, representing a trade-off between surface tension and elastic energies. In this work, we use statistical physics tools to investigate the thermodynamic stability of such fibers in more realistic conditions.
10:48AM F30.00013: Role of Geometrical Frustration in Self-limiting Enantioselective Synthesis of Chiroptical Helices  PRASHANT KUMAR (Presenter), JIAO YAN, ALEXANDER F SIMON, DANIEL KATZ, Univ of Michigan - Ann Arbor, DOUGLAS HALL, GREGORY GRASON, University of Massachusetts Amherst, NICHOLAS KOTOV, Univ of Michigan - Ann Arbor — Tunable rotation of light polarization across a wide wavelength spectrum is a desired property for optoelectronic materials. Nanoscale helices and their segments (bow-ties) are expected to exhibit some of the strongest chiroptical activity among nanoscale structures with mirror asymmetry. Successful efforts for fabrication of helices with desired geometry (pitch, length, width, twist angle and thickness) have been focused on top-down approaches such as ion-beam lithography. However, lithographic methods are limited by the fabrication efficiency of the instrumentation involved, thereby hindering bulk production. Herein, we present a colloidal synthesis route for enantiopure bow-ties by guiding the electrostatic and coordination interactions between cadmium ions and chiral amino acid cysteine (Cys). Cd-Cys bow-ties are self-assembled from sheet-like monomeric units, with individually controllable length, width and pitch, leading to tunable chiroptical activity across 500 nm to 3 μm wavelength range. This self-limiting structure of bow-ties can be described within the theoretical framework of geometrical frustration and provide chemical design rules for controlling the interaction and bending energy of monomeric units.

Session F31 DSOFT GSNP DPOLY: Wetting and Adhesion of Soft Materials: Dynamics and Instability II 503 - Etienne Barthel, ESPCI Paris

8:00AM F31.00001: Multiphase Flow Through Hairy Channels  CHRISTOPHER USHAY (Presenter), ETIENNE JAMON-PUILLET, PIERRE-THOMAS BRUN, Princeton University — Surfaces textured with long, flexible fibers are ubiquitous in nature and often serve vital functions in multiphase systems. Cilia in lung epithelia transport mucus along airways, while the fur of semiaquatic mammals entrains air for insulation while swimming. Inspired by their versatility, we fabricate “hairy” elastic surfaces by casting a curing elastomer in laser-cut acrylic molds. Specifically, we apply arrays of deformable posts in model systems for the displacement of immiscible phases in a Hele-Shaw cell patterned with elastic features, wherein the buckling of the obstacles modifies the local geometry and thus has a strong effect on drainage. By displacing the oil with water at \( \text{Ca} \ll 1 \), we study the geometry and contact line dynamics of the evolving interface and the impact of confinement on oil removal. Models for depth-averaged fluid flow and the deflection of elastic beams are adapted to our problem to describe the deformation of the host medium due to interfacial and viscous forces. We find the oil phase captured in bundles, in quantities that differ significantly from the undeformed reference case; this has implications towards both enhanced oil recovery and the development of liquid-infused surfaces, which possess properties such as omniphobicity and drag reduction.
8:12AM F31.00002: Rate control of blister inflations and the skin patterns*  TONG SHEN
(Presenter), EDUARD BENET CERDA, FRANCK J. VERNEREY, University of Colorado, Boulder — Surface blistering is commonly observed in various biological processes such as cell apoptosis and locomotion. Despite the variety between systems, blister formation and growth are characterized by the delamination of a thin viscoelastic membrane from its substrate, followed by its large deformation (>100 %) as it is inflated by the infiltration of interstitial fluid. The dynamic of this process is controlled by three rates: the inflation rate, the skin’s viscoelasticity and the delamination rate. Through a combination of experiment and theoretical modeling, we find that competition between these time scales may trigger two instabilities, namely the membrane’s thinning instability and the delamination instability. Utilizing the interplay between these two mechanisms, we are able to control the equilibrium shape of a blister by simply mediating its inflation rate. These findings are then used to understand the surface blisters observed on thermo-sensitive hydrogels as they quickly deswell during their volume phase transition. By understanding the mechanism that governs the interplay between blister inflation and solvent transport, one can explain a diversity of skin patterns observed on the gel surface for different temperature and the gel's crosslink density.

*NSF Award No. 1761918

8:24AM F31.00003: Rupture noise of a moving contact line*  CAISHAN YAN (Presenter),
Department of Physics, Hong Kong University of Science and Technology, DONGSHI GUAN, State Key Laboratory of Nonlinear Mechanics, Institute of Mechanics, CAS, China, PIK-YIN LAI, HSUAN-YI CHEN, Department of Physics, National Central University, Taiwan, PENERG TONG, Department of Physics, Hong Kong University of Science and Technology — Many disordered systems exhibit crackling noise when driven by an external force or filed, such as Barkhausen noise in magnetization of ferromagnetic materials, acoustic emission in plastic deformation and seismic activity in earthquakes. Here, we report the avalanche statistics of a moving contact line (CL) pulled by an AFM-based hanging glass fiber through a liquid-air interface. The measured capillary force acting on the circular CL between the liquid-air interface and fiber surface exhibits zig-zag fluctuations, resulting from stick-slip motion of the CL. In the stick state, the measured capillary force increases linearly with CL displacement. Once it reaches a critical value, the CL slips quickly in the form of avalanches, accompanied by a loss of capillary force $\delta f$. We found that the measured $\delta f$ follows a power-law distribution and the power-law exponent agrees with the predicted value by the ABBM model. The experimental results reveal novel features of the stick-slip dynamics and can help to understand other stick-slip phenomena.

*Work supported in part by the Research Grants Council of Hong Kong SAR.
8:36AM F31.00004: Soft Wetting and Phase Separation on Swollen Polymer Networks
ZHUOYUN CAI (Presenter), JONATHAN PHAM, Univ of Kentucky — When a water drop is deposited on a soft adhesive substrate, the surface tension of water drives deformation of the substrate to increase contact area; this is commonly known as soft wetting. In recent soft wetting theories, elastic forces and surface stress oppose substrate deformation. However, very soft, crosslinked materials often contain a liquid phase (i.e. solvent) and is can be considered a swollen network. For a covalently crosslinked network, solvent may separate from network near the contact line to minimize the elastic energy. Although phase separation near contact lines have been considered, the phase distribution at the contact zone is not well understood, and the condition required for phase separation is unclear. We implement confocal microscopy to visualize the crosslinked polymer and solvent phase separately during soft wetting. By controlling the degree of crosslinking and swelling ratio, we investigate both the solvent leeching and the deformation of the network. We find that phase separation does not clearly occur when the swelling ratio is small. We expect that examining the microscale contact zone will help in developing a theory for wetting of soft gels.

8:48AM F31.00005: Spreading dynamics of water onto soluble polymer coatings with hydrophobic insoluble patterns
SOLOMON S. MELIDES, CPE, U.Surrey, JONATHAN E. BROWN, Food Science and Nutrition, U.Surrey, JOSEPH L. KEDDIE, Physics, U.Surrey, MARCO RAMAIOLI (Presenter), UMR 782, Institut National Recherche Agronomique (INRA) — The wetting of many food powders is affected by hydrophobic ingredients present at the surface, such as fat. Instant beverages, soups and infant formulas are typical examples. The spreading of sessile droplets on homogeneous soluble polymer films is dominated by the hydration resulting from water evaporation and condensation ahead of the moving contact line\textsuperscript{1,2,3}, resulting in a strong dependence of the contact angle ($\theta$) on the contact line speed ($U$), film thickness and local water content. This study introduced surface heterogeneity by inkjet printing hydrophobic fat patterns at controlled area fractions 0-50% onto thin soluble polymer coatings of maltodextrin to assess the impact on the water spreading dynamics, at controlled ambient RH. Increasing the area coverage increased strongly $\theta$, for every $U$. A surface coverage of 26.3% was found to halve $U$ after 10 s of spreading. Fat patterns were shown to alter both the interface shape and the contact line length. A theory is proposed to describe the impact of these hydrophobic insoluble patterns on the water spreading dynamics.

9:00AM F31.00006: Tape Loop Adhesion  THERESA M ELDER, TIMOTHY J TWOHIG, ANDREW CROLL (Presenter), North Dakota State Univ — A common method of adhering two parallel surfaces to each other is to place a tape loop between them. Despite the tape loop’s prevalence there has, to our knowledge, been no full description of the mechanics of this system to date. We attack the problem experimentally using a reduced half-loop geometry, which is moved through a compression-retraction (sticking then peeling) cycle from which force-displacement curves are measured. We also imaged the shape of the loop during the experiment with photography and laser scanning confocal microscopy. By using both polydimethylsiloxane (PDMS) and polycarbonate (PC) as ‘tape’ materials, we explored the mechanics of both ‘tacky’ and dry adhesive systems. Notably, we find that the compression curve is completely insensitive to surface interactions. Adapting the ‘sticky-elastica’ model of Majidi and Vella, we show how the entire cycle can be described using only an elastic modulus and critical energy release rate as inputs. Remarkably, a complete model of the cycle allows us to create an incredibly simple measurement of adhesion, involving only a ruler.

9:12AM F31.00007: Elastocapillarity and Rolling Dynamics of Solid Nanoparticles*  YUAN TIAN (Presenter), HEYI LIANG, ANDREY DOBRYNIN, Polymer Science, The University of Akron — We use molecular dynamics simulations of rolling dynamics of solid nanoparticles with size $R_p$ in contact with soft elastic substrates to elucidate effect of capillary, elastic and friction forces on rolling motion. Our simulations have shown that a nanoparticle can be in stationary, steady rolling, and accelerating states depending on the nanoparticle-substrate work of adhesion, $W$, the magnitude of the net applied force, $F$, and the substrate shear modulus $G$. In the stationary state, the restoring torque produced in the contact area balances the torque due to the external force. The crossover rolling force $F_r$ is proportional to $WR_p$. In the steady rolling state, $F > F_r$, the nanoparticle maintains a constant rolling velocity which is a manifestation of the balance between the rolling friction force and the applied force. The observed scaling relationships between the applied force and nanoparticle velocity reflect a viscoelastic nature of the substrate deformation dynamics. A nanoparticle begins to accelerate when the energy supplied to the nanoparticle exceeds the energy dissipated in the contact area due to viscoelastic substrate deformation. Using these simulation results, we have constructed a diagram of states in terms of dimensionless parameters $F/WR_p$ and $W/GR_p$.

9:24AM F31.00008: Understanding Elastomeric Contact Interfaces in the Presence of Water*

NITYANSHU KUMAR (Presenter), SUKHMANJOT KAUR, SIDDHESH DALVI, ALI N DHINOJWALA, Univ of Akron — The traction of tires in the rain or sticking a bandage on wet skin involves understanding the role of interfacial water in adhesion and friction. In most cases, the contact interfaces are not completely dry or wet and instead show patchy contact. Even for smooth surfaces, the contact can be patchy due to difficulty in draining the water upon contact. In this work, we have studied the contact interface between hydrophobic PDMS and hydrophilic sapphire substrate in dry and wet conditions using infrared-visible sum-frequency generation (SFG) spectroscopy and macroscopic Johnson-Kendall-Roberts (JKR) adhesion measurements. SFG spectroscopy provides information on interfacial water and shows direct spectral peaks associated with the surface -OH groups in contact with either water or PDMS elastomers. This molecular information can be directly correlated with the macroscopic work of adhesion, adhesion hysteresis, and friction. We will discuss how the presence of interfacial water is affected by normal load and velocity.

9:36AM F31.00009: Universal Scaling Behavior of the Tackiness of Polymer Melts

YOU WANG, AIPING ZHOU, XIAORONG WANG (Presenter), School of Chemical Science and Engineering, Tongji University — This presentation describes the measurement of stickiness or tackiness, as measured by the peak force to pull off a cylindrical probe from neat polyisoprene melts, the latter of varying materials and surface roughness, over a range of separation speeds. The polymers were either linear or star-branched, with the molecular weights of the former ranging from 84 to 476 kg/mol and of the latter from 609 to 1130 kg/mol. Dynamic mechanic measurements of the polymers showed normal and classic behavior to this well-characterized system. We find that when the pulling speed ($V_s$) is greater than a critical speed ($V_c$), the maximum tack force ($F_{max}$) can be generally described by the following scaling relationships: $F_{max} \sim V_s^{1/3}$ and $F_{max} \sim t_{max}^{-1/2}$, where $t_{max}$ the time when the maximum force is reached in the force-time profile. Remarkably, this scaling behavior of the tackiness appears to be universal as it is independent of the adhered surface, the molecular weight distribution, and the linear or branched chain architecture of the polymer melt. We connect these relations to the physics whereby the tack is controlled by the crack propagation along the interface.
9:48AM F31.00010: Spreading dynamics of water droplets on hydrophilic surfaces*  MESFIN TSIGE (Presenter), SELEMON BEKELE, Univ of Akron — In the early stage of droplet spreading, the inertia of the drop resists the capillary driven motion, and for liquids with low viscosity the spreading radius has been observed to grow with time as \( r(t) \sim t^{1/2} \), independent of surface wettability. In the final stages, the effect of viscous forces acting in the neighbourhood of the three phase contact line become relevant and the competition between surface tension and viscous forces results in extremely slow spreading dynamics and follows what is called Tanner's law, \( r(t) \sim t^{1/10} \). In this work, we will present results on the spreading behaviour of water droplets of varying sizes on a completely wetting surface investigated using fully atomistic molecular dynamic simulations. The spreading observed is characterized by a monolayer of molecular dimensions that moves ahead of the main bulk part of the droplet. Interestingly, the bulk part initially spreads over the monolayer with increasing radius until a characteristic time \( t^* \); thereafter, the bulk radius shrinks maintaining a constant contact angle until it disappears altogether. We will show that a first principle model based on hydrodynamic theory describes the spreading data rather well in the regime where the low contact angle approximation holds.

10:00AM F31.00011: Multi-scale model of gas transport through soap-film membranes used for Artificial Photosynthesis* GABRIELE FALCIANI (Presenter), Politecnico di Torino, RICARDO FRANKLIN, ALI HASSANALI, International Centre for Theoretical Physics, ELIODORO CHIAVAZZO, Politecnico di Torino — This activity is part of the recently funded SoFiA project aiming at a new concept of soap-film photosynthetic membrane for carbon dioxide conversion into fuel [1]. Here, we specifically focus on gas transport through those membranes realized in the form of functionalized soap-films. Diffusion phenomena in the water core and surfactant monolayers are described by Fick's law [2, 3]. Molecular dynamics is used to compute the surfactant distribution and orientation in the membrane monolayers assuming hexaethylene glycol monododecyl ether (C12E6). The obtained atomistic details are then incorporated in a continuum model describing transport phenomena at a larger scale. Numerical predictions are validated against experimental data from literature and used to estimate the characteristic time for fuel-oxygen mixing when separated by photosynthetic soap film membranes.

The role of crystallization, dewetting, and contact angle in the formation of high aspect ratio crystals

MATHEW GISO (Presenter), Physics & Astronomy, Tufts University, HAODA ZHAO, PATRICK T SPICER, Chemical Engineering, University of New South Wales, TIM ATHERTON, Physics & Astronomy, Tufts University — High aspect ratio crystals have many applications including improved delivery of important ingredients in consumer products. We present a process to produce crystals with a controllable aspect ratio using just oil and water in an easily scalable process. When an oil in water emulsion crystallizes, generally crystallization occurs so quickly the droplets do not deform. By adding surfactants the remaining liquid fraction can be forced to eject the crystals as they grow resulting in an elongated crystal. The contact angle the oil droplet makes with the crystal does not remain constant during this process. The rate of dewetting can be tuned by varying the surfactant concentration. The rate of crystallization can be controlled by vary how quickly the system cools. We examine the crystallization and dewetting behaviors by using a non-equilibrium Monte Carlo model. We examine the behavior of the contact angle using a semi-analytical geometric model. Our results give insight into how the contact angle changes and the dependence of the final crystal morphology on the dewetting and crystallization rates.

Detection of Polypeptide Conformational Transitions in Solution via Sound Velocity and Optical Rotation

*ALYSSA BLAKE (Presenter), GRAHAM PARKINSON, PAUL RUSSO, Georgia Inst of Tech — Of the many different core-shell particles being designed for drug delivery, protein sequestration, and other applications, polypeptide-coated silica is among the most promising. The combination of a configurable, chiral surface and a wide spectrum of surface moieties is difficult to match using conventional polymers. A model system for such polypeptide-silica composite particles (PCPs) has been constructed by covalent attachment of poly (ε-carbobenzyloxy-L-lysine) (PCBL) to silica microbeads. PCBL exhibits a reversible coil-helix transition when dissolved as a pure polymer in m-cresol, but the use of conventional optical methods (e.g., circular dichroism) to confirm such a transition for particles tethered to silica beads is confounded by solvent opacity and strong scattering. Sound velocity measurements provided comparable results to the conventional methods, such as optical rotation, but allows for optically active solvents and strongly scattering samples to be more easily measured. The combination of these two methods provides a new way to understand polypeptide transitions in complex environments and real-world formulations.

Giant hyaluronan polymer brushes display polyelectrolyte brush polymer physics behavior

*JESSICA FAUBEL (Presenter), School of Physics, Georgia Institute of Technology, RHIDDI P PATEL, School of Materials Science and Engineering, Georgia Institute of Technology, JENNIFER CURTIS, School of Physics, Georgia Institute of Technology, BLAIR K BRETTMANN, School of Materials Science and Engineering, Georgia Institute of Technology — We report on the polyelectrolyte brush behavior of extra-large hyaluronan polymer brushes (~15 microns) recently developed using an enzyme-mediated growth process. The giant height of the brushes enables direct characterization of 3D structure and time-dependent behavior. In this study, we explored the stimulus response of the brush to ionic strength and solvent changes. The brush displays classic osmotic brush and salted brush regime behaviors. In poor solvent (ethanol), the brush collapse by 96%. The collapse is rapid when changing from a good to a poor solvent, but re-expansion is extremely slow when changing back to a good solvent. The observed brush behavior is similar to that seen for smaller polyelectrolyte brushes, indicating that these ultra-thick brushes will serve well as model systems to study more complex phenomena, including dynamics, through confocal microscopy

9:00AM F32.00004: Detecting Bacteria with Plasmonic Microcapsules* REMI DREYFUS (Presenter), CNRS, CÉLINE BUREL, Solvay, CHRISTOPHER B MURRAY, UPENN, BERTRAND DONNIO, CNRS — Assembling nanoparticles into dispersible colloidal pH-sensitive sensors remains a challenge. Here, we show how to combine optically active plasmonic gold nanoparticles and pH-responsive thin shells into “plasmocapsules”. Upon pH change, plasmocapsules swell or shrink. Concomitantly, the distance between the gold nanoparticles embedded in the polymeric matrix varies, resulting in an unambiguous color change. Billions of micron-size sensors can thus be easily fabricated. They are non-intrusive, reusable, and sense local pH changes. Each plasmocapsule is an independent reversible microsensor over a large pH range. Finally, we demonstrate their potential use for the detection of bacterial growth, thus proving that plasmocapsules are a new class of sensing materials

9:12AM F32.00005: Enzyme-Responsive Materials for Regenerative Medicine [Invited] SARAH HEILSHORN (Presenter), Stanford Univ — In living materials, the tissue-level structure is constantly being remodeled through the molecular action of cell-secreted enzymes. Bioactive materials have been designed previously to respond to these enzymes through cleavage of individual molecular bonds. However, the resulting changes in the tissue-level material architecture has been underappreciated as a potential material design parameter that can impact cell function. Combining our experimental measurements of chemical reaction rates with a simple model of percolation network theory, we were able to accurately predict how tissue-level network structure evolves in an engineered biomaterial over time. We then demonstrated that encapsulated human endothelial cells respond to these tissue-level structural changes by forming vascular-like networks. In another example of molecular-level design enabling control of tissue-level structure and cell biology, we engineered a material for proliferating neural stem cells. Upon encapsulation, neural stem cells only maintained their stem-like behavior if they could sufficiently remodel the material through the action of a cell-produced enzyme. We further demonstrated that neural stem cell differentiation into more mature cell types is also dependent on tissue-level structure. Thus, this body of work has introduced material remodeling and tissue-level structural dynamics as key design criteria for the field of biomaterials.
Shape Control of Charge-patterned Nanocontainers

Nicholas Brunk (Presenter), Vikram Jadhao, Intelligent Systems Engineering, Indiana University — Stimuli-responsive control of the shape of nanoparticle (NP) containers enables their application as adaptive drug-delivery carriers. NP shape adaptation also provides dynamic building blocks in the design of reconfigurable, biomimetic materials. Molecular dynamics (MD) simulations are used to explore the role of surface charge patterning in controlling electrostatically-driven shape deformation of hollow, elastic NPs. Charge patterns investigated include those commonly synthesized in inverse patchy colloids: Janus particles with (N = 2) patches, striped charge patterns (N > 2), and polyhedral patterns. For Janus patterns, transitions to convex bowl, flattened hemisphere, and concave spinning-top-like conformations occur depending on the salt concentration screening the electrostatic drive to deform. As the number of stripes increases (N > 2), NPs with charged terminating ends adopt disc and rod conformations. However, (N > 2) striped particles with neutral terminating ends form concavities reminiscent of lock-and-key colloids. We also explore the shapes of polyhedrally-patterned nanocontainers and discuss the intersection between pattern-driven and buckling-driven shape control.

A simple mechanical model for synthetic catch bonds

Kerim Dansuk (Presenter), Sinan Keten, Department of Mechanical Engineering, Northwestern University — Catch bonds are protein-ligand bonds which become more difficult to break as the applied force increases, a counterintuitive phenomenon that has not yet been reproduced in synthetic systems. Here, we have demonstrated that a simple mechanical design based on a tweezer-like mechanism can exhibit catch bond characteristics under thermal excitations. The tweezer has a force-sensitive switch which controls the transition of the system to a high-ligand-affinity state with additional ligand-tweezer interactions. Applying kinetic theory to a two-mass-two-spring idealized model of the tweezer, we show that by tuning the shape of the switch and the ligand-tweezer interaction energy landscapes, we can achieve greater lifetimes at larger force levels. We validate our theory with molecular dynamics simulations and produce a characteristic lifetime curve reminiscent of catch bonds. Our analysis reveals minimal design guidelines for reproducing the catch bond phenomenon in synthetic systems such as molecular switches/foldamers, DNA linkers, and nanoparticle networks.

Office of Naval Research Early Career Award, PECASE, grant # N00014-16-1-3175
10:12AM F32.00008: Towards Tumor pH Detection Using Plain Radiography: An Injectable pH-Responsive Polyacrylic Acid Based Hydrogel Biosensor*  
SACHINDRA KIRIDENA (Presenter), UTHPALA WIJAYARATNA, MD, ARIFUZZAMAN, JEFFREY N. ANKER, Department of Chemistry, Clemson University — A pH responsive polyacrylic acid hydrogel based injectable biosensor was developed to measure local tumor pH using plain radiography in order to study cancer pathophysiology, track tumor progression, and determine effectiveness of drugs in vivo. Although plain radiography is unable to detect local chemical concentrations directly, a chemically responsive hydrogel was synthesized to move a tantalum bead and thus report the local concentration. The hydrogel was synthesized by free radical co-polymerization of acrylic acid and n-octyl acrylate and a 13 mm disk of the gel with embedded radiopaque wire had a range of pH 4–8 with a precision of 0.065 pH units. A preliminary study was carried out to miniature this hydrogel sensor and fit it into an injectable porous metal sleeve, all fitting within a breast cancer biopsy marker needle. The 10 mm sensor showed repeatable response to pH cycling in the range of pH 4–8. We are optimizing the sensor for sensing in the pH 6.5 to 7.5 range most relevant to tumor acidosis in order to track tumor physiology and assess response to chemo/radiotherapy.

10:24AM F32.00009: Modulation of hydrogel biophysical properties using photoadaptable chemistry improves formation of intestinal organoids*  
MAX YAVITT (Presenter), TOBIN BROWN, ELLA HUSHKA, Department of Chemical and Biological Engineering, University of Colorado Boulder, PETER DEMPSEY, Department of Pediatrics, University of Colorado Anschutz Medical Campus, KRISTI ANSETH, Department of Chemical and Biological Engineering, University of Colorado Boulder — There is increasing interest to develop well-defined platforms for organoid growth and expansion. It is known that organoid formation from single intestinal stem cells (ISCs) in synthetic hydrogels is influenced by matrix stiffness and can be initiated by hydrogel degradation. Understanding these forces is key to improving efficiency of organoid growth. We use the adaptable allyl sulfide (AS) photochemistry to tune hydrogel biophysical properties through on demand network reorganization. We show that reorganization is dependent on the protonation state of a soluble, monofunctional thiol species. The rate of degradation can therefore be tailored by controlling the thiol pKa or the solution pH. This understanding then guides the selection of conditions that allow for more rapid degradation. Formed using a biorthogonal conjugation reaction, the AS hydrogels support organoid growth from ISCs, which show maintenance of stem cell markers. Intermittent light exposure will be applied in situ to tune the modulus of cell laden hydrogels and the resulting influence on growth, morphology, and presentation of mechanosensitive biochemical markers will be assessed. This understanding can be leveraged to optimize growth of colonies for development of intestinal organoids.

10:36AM F32.00010: Biosensor physics: DNA folding in a crowded environment* MARK TAYLOR (Presenter), Dept. of Physics, Hiram College, WOLFGANG PAUL, Institute for Physics, Martin-Luther-University — At the molecular level, biological systems operate in very crowded environments. It has long been recognized that crowding can affect the stability and phase transitions of the biopolymers comprising such systems. Similar issues arise in developing biotechnology applications based of dense arrays of surface-tethered polymers. In our recent work we directly measure the entropy reduction resulting from crowding/confinement using Wang-Landau computer simulation techniques [1]. Here we discuss the folding transition of a specific stem-loop forming, single-stranded DNA oligomer that has been studied extensively by the Plaxco group [2]. We develop a coarse-grained model for ssDNA (based on a flexible hard-sphere chain with square-well patch interactions that accounts for both H-bonding and base-pair stacking) and use it to examine the entropic effects associated with surface crowding. For the tethered ssDNA oligomer crowded by other tethered oligomers, we find, in agreement with experiment, that both stabilization and destabilization of the folded state are possible depending on the conformational state of the crowders. 10:48AM F32.00011: Effect of Nanoparticle Surface Functionality on Magnetic and Interfacial Properties of Iron Oxide–Poly(ethylene oxide) Nanocomposites* DONOVAN WEIBLEN (Presenter), Materials Science and Engineering, Rensselaer Polytechnic Institute, GRACE L GIONTA, Chemical and Biological Engineering, Rensselaer Polytechnic Institute, DENIZ RENDE, Center for Material, Devices, and Integrated Systems, Rensselaer Polytechnic Institute, PINAR AKCORA, Chemical Engineering and Materials Science, Stevens Institute of Technology, RAHMI OZISIK, Materials Science and Engineering, Rensselaer Polytechnic Institute — Magnetically susceptible nanoparticles (NPs) have shown promise in diverse application areas such as shape memory polymers, membranes, and drug delivery. In the current work, the impact of surface coating of iron oxide (Fe₃O₄) NPs on interfacial heat transfer, bulk magnetization properties, and structure of poly(ethylene oxide), PEO, nanocomposites was explored. Bare, poly(ethylene glycol) (PEG), and amine coated 10–nm-diameter Fe₃O₄ NPs were dispersed at concentrations less than 1% by weight in PEO. When exposed to an alternating magnetic field (AMF), temperature increases for all PEO/Fe₃O₄ nanocomposites. Amine and PEG coated NPs showed an improved heat generation efficiency. Analysis of magnetization curves revealed an unusual result. Amine coated NPs had the strongest magnetization, however, bare NPs showed a stronger magnetization than the PEG coated NPs. Disagreement between magnetization and magnetic heating results implies that interfacial heat transfer is impacted by NP surface modification. Simulations and experiments were carried out to identify the interfacial structure. Specific attention was paid to how the interface changes with applied AMF and how it affects the mechanism of heat transfer.

*This material is based upon work supported by the NSF Grant 1825254.
In many polymers, the connection between morphology and performance is complex, and conventional materials structure measurements are not sufficient to provide a predictive structural model. Nanoscale variations in molecular orientation and composition, particularly in amorphous regions, are thought to be critical, but few techniques can probe them. I will describe our approach to polarized resonant soft X-ray scattering (P-RSoXS), which combines principles of soft X-ray spectroscopy, small-angle scattering, real-space imaging, and molecular simulation to produce a molecular scale structure measurement for soft materials and complex fluids. I will provide a complete description of our newly-constructed P-RSoXS measurement station at NIST beamlines of the National Synchrotron Light Source II. Results from model systems including commodity plastics, block copolymers, and semiconducting polymers will be discussed. An emphasis will be placed on connections between P-RSoXS and small angle neutron scattering (SANS), especially similarities in contrast variation approaches. I will conclude with our progress toward a forward-simulation framework that describes scattering length density at the nanoscale as a three-dimensional tensor. Results from this approach provide previously inaccessible orientation measurements of nanoscale amorphous regions in polymers.

X-ray scattering is a powerful tool to study the structure and dynamics of soft matter on length scales from nanometers to millimeters and time scales from picoseconds to seconds. In the presentation, I will give a brief overview of the scattering techniques and instruments available at the new, high-brightness, NSLS-II synchrotron to study soft and biomaterials and then present the detailed design, parameters and the status of the Soft Matter Interfaces (SMI) beamline. SMI beamline capabilities on the tender x-ray regime will be highlighted since it enables resonant x-ray scattering measurements at the K-edges of key elements to bring new perspectives to the soft matter community: such as the P, Cl for water membrane problematics; Sulfur edge for organo-electronic filed; as well as K, Ca and more edges. The second part of the presentation will focus on a broad overview of the first results obtained at the beamline on a wide range of material, from organo-photovoltaic polymer to liquid membranes. Finally, the development of new in-situ stages, such as heating, shearing opens a wide field of possibilities.

Molecular orientation in polyamide reverse osmosis membranes revealed by polarized resonant soft x-ray scattering

PETER BEAUCAGE (Presenter), National Institute of Standards and Technology — Despite their broad application for water desalination, little is known about the fundamental interplay of synthesis, structure, and water transport in polyamide thin film composite membranes. The active layers of these materials are produced by interfacial polymerization atop a porous support resulting in films of typical thickness 100 nm with > 50 nm RMS roughness, making characterization by conventional techniques extremely challenging. Using polarized resonant soft x-ray scattering, a uniquely sensitive probe of molecular orientation and structure, we observe a striking degree of polarization-induced anisotropy in both commercial and model polyamide films. This anisotropy is likely due to local molecular orientation of C=C and C=O π* electron systems. We compare orientation distributions and optical constants from P-RSoXS with those obtained by angle-dependent NEXAFS and demonstrate a new strategy for signal enhancement of interfacially oriented scattering. This previously-unreported molecular orientation may play a key role in connecting the processing and structure in polyamide thin film composite membranes to their water transport mechanisms, enabling enhanced performance in these important devices.

PAB thanks the NIST-NRC postdoctoral fellowship for support.

Label-free characterization of aqueous molecular micelle nanostructure and dynamics via in-situ RSoXS

TERRY MCAFEE (Presenter), BRIAN AKIRA COLLINS, Washington State Univ, ISVAR CORDOVA, CHENG WANG, Lawrence Berkeley National Laboratory, THOMAS FERRON, Washington State Univ, PHILLIP PICKETT, University of Southern Mississippi — Micelles are key to applications from drug delivery to commercial paints. Their nanostructure and dynamics are of critical importance to their macroscopic properties and functions, but are difficult to measure. Here we demonstrate a novel technique capable of such measurements based on Resonant Soft X-ray Scattering (RSoXS), which is uniquely capable of probing organic materials using their intrinsic chemical bonds rather than laborious and potentially disruptive labeling. Our customized nanofluidic cell enables RSoXS to be performed in liquid environments, allowing structure and dynamics to be measured in-situ for the intended application. We first apply the technique to a model system, Pluronic F127 micelles. Resonant energy contrast tuning allows the internal structure and composition to be measured quantitatively. We further investigate a novel amphiphilic statistical copolymer, “polysoap”, designed for oil spill remediation. Dynamic dual flow reveals an unexpected concentration dependence of the corona, which was not observed with traditional visible light scattering. We further show that despite aggregation, the unimeric core structure is retained, crucial for its application.

*NSF MRI grant 1626566

ISVAR CORDOVA (Presenter), MSD, Lawrence Berkeley National Lab, LUKE LONG, Physics, UC Berkeley, GUILLAUME FREYCHET, NSLS-II, Brookhaven National Lab, CHENG WANG, ALS, Lawrence Berkeley National Lab, PATRICK NAULLEAU, MSD, Lawrence Berkeley National Lab — With the adoption of extreme ultraviolet (EUV) lithography across the semiconductor industry, there comes a need to develop new resist materials that will become the mainstay enabling technology. This development places pressure on the metrology community to develop adequate non-destructive techniques capable of measuring the sub-10 nm patterns that such resists are meant to produce. Recent progress in grazing incidence and resonant x-ray scattering techniques have shown particular promise at being able to address part of these characterization challenges.¹,²

In this work, we show how resonant scattering contrast can harness spatially distributed chemical heterogeneities within exposed resist in order to probe their buried profile. Specifically, by focusing on a novel photoresists containing both organic and inorganic components, we demonstrate the insights into critical parameters gained by performing resonant scattering measurements at various energies and configurations.

---

**10:00AM F33.00007: Revealing Strain-Induced Conjugated Polymer Behaviors with Soft X-Ray Scattering and Spectroscopy**

WENKAI ZHONG (Presenter), GREGORY SU, QIN HU, Lawrence Berkeley National Laboratory, FENG LIU, Shanghai Jiaotong University, WANLI YANG, THOMAS RUSSELL, CHENG WANG, Lawrence Berkeley National Laboratory — Conjugated polymers have generated great interest due to their potential in the fabrication of deformable logic circuits that can be integrated into portable/wearable electronics. Here, we developed a beamline setup that can be capable of probing the bulk- and surface-sensitive data of polymer thin films during tensile test using soft x-ray. The combination of experimental and simulated x-ray spectroscopies assists to uncover the fingerprint of molecular behaviors under strain-stress measurement. Furthermore, to establish the relationship of the molecular evolution and device performances, the charge transport properties of the static strained thin film are also evaluated. We expect this work can contribute to understand the molecular origins of mechanical behaviors associated with the resulting device performances.
10:12AM F33.00008: Polarized resonant soft X-ray scattering reveals local chain orientation in polymer-grafted nanoparticles  SUBHRANGSU MUKHERJEE (Presenter), National Institute of Standards and Technology, JASON STREIT, RICHARD ARTHUR VAIA, Air Force Research Laboratory, DEAN DELONGCHAMP, National Institute of Standards and Technology — Polymer-metal nanocomposites that are based on blends of metal NPs and matrix polymers face numerous design limitations and processing challenges. Polymer-grafted nanoparticles (PGNs) are of interest for applications ranging from structural to photonic and electrical. Many of the potential applications (coatings, adhesives, membrane separators, energy storage, etc.) necessitate co-optimization of functional performance with yield stress and toughness. An understanding of how the micro-architecture determines plasticity and failure modes in PGN assemblies is incomplete largely due to lack of tools to fully characterize the microstructure including local interfacial orientation. Here we show the measurement of local chain orientation in a PS-Au PGN system using polarized resonant soft X-ray scattering. The scattering anisotropy was observed at X-ray energies where the anisotropic contrast was affected by the Carbon K-edge 1s-π* resonance of the polystyrene phenyl group. Simple models of the particle geometry with forward simulation of the scattering pattern are consistent with phenyl ring orientation being ‘face on’ relative to the particle.

10:24AM F33.00009: Combining spectroscopy with DFT for optical models of polarized RSoXS to reveal molecular alignment in nanostructures*  VICTOR MURCIA (Presenter), BRIAN AKIRA COLLINS, Washington State Univ — Polarized Resonant Soft X-ray Scattering (pRSoXS) is uniquely sensitive to local molecular orientation regardless of crystallinity, making it a powerful tool in characterizing various types of nanostructures. Unfortunately, it is difficult to interpret the scattering patterns due to a lack of appropriate optical models. Building block models (BBM), used to measure global orientation in X-ray absorption spectroscopy (XAS) won't work for pRSoXS as it assesses differences in local ordering and means that XAS measurements alone will not provide enough information for an optical model. We have developed a model that combines angle-dependent XAS with density functional theory (DFT) to algorithmically create a biaxial optical tensor for molecules. We first show how the uniaxial approximation (UA) can be applied to the scattering anisotropy (SA) of Copper(II)Phthalocyanine (CuPc) films as measured by pRSoXS by expanding upon the BBM informed by DFT calculations. Then we show how the UA fails to describe the SA measured on poly-3-hexylthiophene (P3HT) films implying the need for a lower symmetry model. By combining DFT calculations with XAS, a model that enables extraction of additional details of local molecular orientation through pRSoXS can be developed.

*DOE Career Award DE-SC0017923
10:36AM F33.00010: Control of solvent aggregation to impact active layer morphology and enhance performance in non-fullerene organic solar cells  GUOYAN ZHANG (Presenter), SINTU RONGPipi, BROOKE KUEI, ENRIQUE D GOMEZ, Penn State — The use of solvent additives in the active layer casting solution has proved to be an effective strategy to enhance the performance of solar cells. Solvent additives often have high boiling points, can enhance or reduce solubility, and thereby promote polymer aggregation in solution prior to spin-coating. As a consequence, the use of solvent additives can facilitate the crystallization process. The resulting ordered structure can remarkably increase charge photogeneration, carrier lifetime, and carrier mobility.

Recently, we have found that volatile solvent additives can also improve the performance of organic solar cell fabricated with solution-processed non-fullerene acceptors, including Y6 to achieve device efficiencies in excess of 10%. We examined the effects of solvent quality on the structure in solution of both the donor and acceptor, and the resulting effects on film morphology and performance in solar cell devices. A combination of resonant soft X-ray scattering, grazing-incidence wide-angle X-ray scattering, energy-filtered TEM, and ultrafast spectroscopy reveal the complex interplay between solution structure and subsequent film structure through perturbations induced by solvent additives.

10:48AM F33.00011: Controlling Ionomer Phase Separation Through Side-Chain Engineering  GREGORY SU (Presenter), ISVAR CORDOVA, Lawrence Berkeley National Laboratory, WILLIAM WHITE, University of California, Irvine, MATTHEW LINDELL, MICHAEL YANDRASITS, 3M Corporation, LAWRENCE RENNA, University of California, Irvine, JUN FENG, Lawrence Berkeley National Laboratory, SHANE ARDO, University of California, Irvine, CHENG WANG, AHMET KUSOGLU, Lawrence Berkeley National Laboratory — Phase separation in perfluorinated ion-conducting polymer, or ionomer, membranes defines pathways for ion transport and controls overall conductivity. However, this phase-separated morphology is difficult to characterize and challenging to control based on molecular-level insights. Herein, we show two strategies to control phase-separation and domain spacing in perfluorinated ionomers, and resonant X-ray scattering is used to provide enhanced contrast and chemical sensitivity to decipher nanoscale morphology. Perfluoro ionene chain extended ionomers containing two or three ionic groups per side-chain exhibit tunable domain spacing based on side-chain length. Furthermore, the chain extended ionomers have greater long-range order and higher proton conductivity and water uptake compared to conventional perfluorinated sulfonic acid ionomers. Perfluorinated sulfonic acid ionomers with photoacid dyes covalently bound to side-chain ends, which are promising for light-driven ion conduction, reveal a phase-separation length scale that increases with increasing dye content. Overall, these studies provide insights into detailed connections between polymer chemistry and phase-separated morphology to inform molecular-level design of next-generation membranes.

Session F34 DPOLY DSOFT GSNP DFD: 3D Printing of Polymers and Soft Materials I 506 - Anthony Kotula, National Institute of Standards and Technology - Tag(s): Focus
8:36AM F34.00002: Re-Printable, Self-Healing Polymer Networks*  
SVETLANA SUKHISHVILI (Presenter), Department of Materials Science and Engineering, Texas A&M University, FRANK GARDEA, Army Research Laboratory South, U.S. Army Combat Capabilities Development Command, QING ZHOU, Department of Materials Science and Engineering, Texas A&M University — We report a versatile approach to designing 3D printable, re-processable dynamic covalent networks with controllable mechanical properties. The approach involves synthesis of epoxy-based oligomeric building blocks of controllable length which are then reversibly crosslinked using the Diels-Alder (DA) reaction. The networks demonstrate several features which are beneficial for additive manufacturing, such as reversible dissociation to liquids at temperatures above 110 °C and fast curing during fused deposition modeling. Moreover, DA reactivity of the precursor material improved interlayer adhesion during printing and enabled self-healing. Using this approach, a series of networks with glass transition temperatures controlled between -10 and 35 °C and the elastic moduli between 10 MPa and several GPa were demonstrated. Finally, the 3D printed networks exhibited shape-memory effects which are based on the stereochemical characteristics of DA adducts.

8:48AM F34.00003: Reactive Processing in Extrusion based Polymeric 3D Printing with Surface Segregating Additives*  
NEIKO LEVENHAGEN, MARK DADMUN (Presenter), University of Tennessee, Knoxville — Fabricating complex geometries with isotropic, robust mechanical properties by fused deposition modeling (FDM) remains a key target in expanding additive manufacturing towards the production of large scale commercially relevant structures. Due to the large size of polymer chains and the complex thermal environment experienced by the printed filament in FDM, entanglement of polymers between layers is incomplete, resulting in weak inter-layer interfaces and unsatisfactory Z-strength. Recently, our group has addressed these issues by developing novel polymer materials for FDM that revolve around the introduction of low molecular weight surface segregating additives (LMW-SuSAs) to the filament. We have recently expanded this concept to reactive additives, including methacrylate terminated linear and 3-arm PLA LMW-SuSAs. These reactive additives can now form inter-layer crosslinks by rational introduction of UV photo-initiators and fiber-optic based UV illumination. In situ reactive processing of the printed layers results in drastic increases in the transverse tensile stresses of the printed layers up to ~140% and ~200% for the linear and 3-arm LMW-SuSAs respectively to create essentially isotropic materials.

9:00AM F34.00004: 3D Printing Polylactic Acid: modelling residual alignment, annealing and templated crystallinity*  CLAIRE MCILROY (Presenter), School of Mathematics & Physics, University of Lincoln, RICHARD S GRAHAM, School of Mathematical Sciences, University of Nottingham, DARIO CAVALLO, University of Genoa, JON SEPPALA, ANTHONY KOTULA, National Institute for Standards and Technology — Polylactic acid is a semi-crystalline polymer melt commonly used in extrusion-based 3D printing applications. This involves extruding molten polymer through a nozzle and depositing filaments layer-by-layer. Rapid cooling and solidification ensures the structural integrity of the printed part.

Since the crystallization kinetics are typically slow, there is insufficient time above the glass transition for crystallinity to develop. Thus, deposited filaments usually have an amorphous micro-structure upon solidification. Moreover, the deposition flow stretches and orients the polymer molecules, and residual alignment becomes trapped in the weld regions between deposited filaments at the glass transition. We propose that this micro-structure leads to reduced weld strength.

Post-processing thermal annealing may be employed to increase the crystal content and improve mechanical properties. However, we find that non-uniform properties are inevitable. Residual polymer stretch can "template" flow-induced nuclei into the weld regions. Upon annealing these nuclei grow into much smaller spherulites, whose size depend on both print speed and temperature.

9:12AM F34.00005: Determination of polymer chain orientation in 3D printed filaments using Polarized Raman spectroscopy and Birefringence* NORA HASSAN (Presenter), JONATHAN SEPPALA, ANTHONY KOTULA, ANGELA HIGHT WALKER, KALMAN MIGLER, National Institute of Standards and Technology (NIST) — To study orientation and alignment of molecular chains in 3D printed polycarbonate filaments, we used a combination of polarized Raman spectroscopy and birefringence measurements. By changing the orientation of the sample with respect to polarization of incident radiation, we probe changes in the ratio between orientation-dependent vibration modes and orientation-independent modes. Raman measurements show that in 3D printed filaments, little to no orientation at the monomer level was detected, supporting molecular dynamics simulation results [1]. Birefringence measurements were compared to the intrinsic birefringence of 0.2, to estimate the degree of orientation. Measured values of birefringence suggest minimal orientation in agreement with the results of Raman measurements. 3D printed filaments were pulled at different draw ratios after annealing to estimate the limit of Raman measurements’ sensitivity to chain orientation in 3D printed fibers through comparison with birefringence measurements.

9:24AM F34.00006: Mechanical Properties of an Additively Manufactured Cyanate Ester
MARISSA GIOVINO (Presenter), National Research Council, HILMAR KOERNER, JEFFERY BAUR, Air Force Research Lab - WPAFB — Additive manufacturing is a recent processing method that allows facile fabrication of complex geometries. Additive manufacturing of thermoset composites is commonly done using an extrusion based method termed direct ink writing. Most direct ink writing materials systems have been epoxy based. Epoxy has good mechanical properties but poor thermal stability. To improve the thermal stability a high temperature thermoset resin, bisphenol e cyanate ester, was selected for 3d printing. The cyanate ester was filled with fumed silica to enable direct ink writing. The high temperature thermoset is a brittle material. Inorganic nanoparticles were used to toughen the cyanate ester composite.
Effect of Chain Alignment and Entanglements on Thermal Welding in Fused Filament Fabrication

MARCO GALVANI (Presenter), MARK ROBBINS, Johns Hopkins University — 3D printed structures are often substantially weaker than those made with conventional techniques, but the reason has been unclear. Indeed alignment from flow during deposition was expected to reduce the number of entanglements and thus accelerate welding of filaments through interdiffusion. To address this puzzle we performed molecular dynamics simulations of welding between polymer melts with different degrees of initial alignment. Standard measures of the entanglement density, such as primitive path analysis, indicate significant entanglement loss with increasing alignment, but contrary to existing theories there is no change in the rate of interdiffusion or reorientation. The distance polymers have diffused and the number of entanglements formed across the interface are independent of initial alignment, and chain reorientation always occurs on the equilibrium disentanglement time. Despite this, mechanical tests show that parts welded from aligned states are weaker. We show that this is due to residual alignment in regions near the weld that yield before the weld. The maximum shear strength and fracture energy of systems containing a weld are the same as systems starting from uniform melts with the same alignment.

Supported by NSF through CMMI-1628974 and by CNPq-235249/2014-9.

3D Printing of Polymers and Soft Materials [Invited]

JON SEPPALA (Presenter), National Institute of Standards and Technology — Soft matter 3D printing (3DP) is a rich and diverse research area with new technologies, materials, and processes entering the literature at a rapid pace. Advancements in “traditional” soft 3DP and materials are giving way to hybrid or entirely new processes and materials designed for 3DP. These advancements have been supported by improvement of in-situ process characterization, a more complete understanding of critical material physics, and focused modeling efforts. Soft 3DP processes can now create function from structure and new materials allow the combination of 3DP and self-assembly, producing features at unprecedented length scales. Models, tuned with in-situ process measurements, predict voxel-by-voxel changes in material properties and combining modeling and multi-material printing has enabled advancements in soft robotics, stimuli-responsive materials, and 4D printing. Further, these advancements are pushing the field toward realizing one of the original promises, complete design freedom. This talk will cover “traditional” and emerging soft 3DP processes, material physics, measurement and modeling challenges, and opportunities.
10:24AM F34.00009: Using Eigenvector Centrality to Predict the Mechanical Properties of Structured Materials  CYNTHIA WELCH (Presenter), PAUL WELCH, BRIAN PATTERSON, MATTHEW HERMAN, LINDSEY KUETTNER, Los Alamos National Laboratory — We seek to link mesoscale organization to macroscopic mechanical response using a combination of 3D printing, mechanical testing, and theory. Our ultimate objectives are to provide a simple reduced-order model for predicting mechanical parameters for tailored structures and to better inform engineering models. Here, we report our efforts toward accomplishing these objectives by examining a set of lattice structures with controlled strut deletion. Octet lattice structures overlaying body-centered cubic unit cells were 3D-printed at two different length scales, using either the two-photon polymerization (2PP) method or the vat photopolymerization method with commercially available acrylate-based resins. A set of 10 lattice structures were printed in which struts were randomly removed to give a fraction of deleted struts up to 0.35, and each sample was compression-tested to obtain the Young's modulus. We applied graph theoretical tools typically used in complex network theory to analyze this set of samples. In particular, we propose that the bulk mechanical properties are dictated by a network free energy calculated from the principle eigenvector of the adjacency matrix encoding the mesoscopic structure.

10:36AM F34.00010: Mechanical Enhancement of Polydopamine Nano-Coatings via Thermal Annealing*  KATERINA G MALOLLARI, PEYMAN DELPARASTAN (Presenter), University of California, Berkeley, TANNER FINK, HELEN ZHA, Rensselaer Polytechnic Institute, PHILLIP B MESSERSMITH, University of California, Berkeley — Inspired by the adhesive proteins of mussels, polydopamine (pDA) has become one of the most widely employed methods for functionalizing material surfaces, powered in part by the versatility and simplicity of pDA film deposition. Despite the widespread adoption of pDA as a multifunctional coating for surface modification, it exhibits poor mechanical performance and it still remains a challenge to improve its mechanical properties without sacrificing functionality and versatility of pDA. Here, we demonstrate thermal annealing at a moderate temperature (130 °C) as a facile route to enhance mechanical robustness of pDA coatings. Chemical spectroscopy, x-ray scattering, molecular force spectroscopy and bulk mechanical analyses indicate that monomeric and oligomeric species undergo further polymerization during thermal annealing, leading to fundamental changes in molecular and bulk mechanical behavior of pDA. Considerable improvements in scratch resistance and elastic modulus were noted for the annealed pDA coating, indicating the enhanced ability of the annealed coating to resist mechanical deformations, possibly due to cross-linking and increased intermolecular and cohesive interactions in the pDA structure.

10:48AM F34.00011: The Role of Ionization in Thermal Transport of Solid Polyelectrolytes
TENGFEI LUO (Presenter), XINGFEI WEI, Aerospace and Mechanical Engineering, University of Notre Dame — Amorphous polymers are known as thermal insulators, but increasing their thermal conductivity has not been guided by fully understood physics. In this work, we use molecular dynamics simulations to study the thermal transport mechanism of solid polyelectrolytes, poly(acrylic acid) (PAA) and its ionized forms. The thermal conductivity of PAA increases monotonically with the ionization strength. Although stronger ionization induces larger Coulombic interactions, the Coulombic interaction does not directly contribute to the thermal conductivity enhancement. Instead, it enhances thermal transport through the Lennard-Jones (LJ) interaction. The strong Coulombic force between the counterion and the ionized carboxylic group shifts the LJ force to the stronger LJ repulsive regime, which is mainly responsible for the improved thermal conductivity.

Session F35 DPOLY DSOFT: Biopolymer Structures and Assemblies 507 -
John Dorgan, Michigan State Univ - Tag(s): Focus

8:00AM F35.00001: BREAK —

8:36AM F35.00002: From Modeling Free Chains with the Rosenbluth Algorithm to Modeling Rigid, Compact, and Overlapped Chains with Our Developed Algorithm EBTISAM ALDAIS (Presenter), Biomedical Engineering, Imam Abdulrahman bin Faisal University, SCOTT RUSSELL CRITTENDEN, Physics & Astronomy Department, University of south Carolina — In 1955, Rosenbluth developed a chain-growth technique for Self-Avoiding Random Walk (SARW) with a set of weights that allows one to approximate all possible configurations of a real chain in a cubic or square lattice. We incorporate the Boltzmann factors for intermolecular bending energy into the monomer growth direction choice in the Rosenbluth algorithm to model chains of arbitrary nearest-neighbor rigidity. This allows for the consideration of compact, free, or extended chains. We validate against, and compare to, various other results, showing very good agreement with known results for short chains and demonstrate the ability to model chains up to 500 segments long, far beyond the length at which the normal Rosenbluth method becomes unstable for reasonable non-zero bending energies. Furthermore, we incorporate the Boltzmann factors for finite overlap energy to model chains that allow only two segments to overlap, Single-Overlapped Random Walk (SORW), into our algorithm. Again, we validate our results with a complete set of SORW for short chains. Our developed algorithms can be easily modified to model any configuration, stiff, free, compact, or overlapped, of polymer-like molecules in biological and non-biological systems.
8:48AM F35.00003: Simulations of Grafted Methylcellulose Chains in Solution*
VAIDYANATHAN SETHURAMAN (Presenter), KEVIN D DORFMAN, University of Minnesota — Recent experiments on methylcellulose chain grafted with polyethylene glycol in solution showed inhibition in methylcellulose fibril formation at high grafting density. We utilize coarse-grained molecular dynamics simulations to understand the influence of grafting on methylcellulose chains. The interaction between the grafts and the methylcellulose chains, as well as the grafting density, are systematically varied. Single chain simulations show that the precursor toroidal structure responsible for fibril formation is hampered by the graft, while Multi chain simulations show that the distance between the centers of masses of the chains increase beyond the minimum capture radius required for fibril formation at high grafting densities. We further demonstrate that conformational fluctuations are suppressed with increasing grafting density. Together, our results support the suppression in fibril formation in grafted methylcellulose systems.

9:00AM F35.00004: Random Copolymer Complexation with Proteins and Possible Applications*
JEREMY WANG (Presenter), BAOFU QIAO, TRUNG NGUYEN, JOHN TORKELSON, MONICA OLVERA DE LA CRUZ, Northwestern University — Random copolymers are polymers made of two or more monomer components, with their properties determined by the statistical distribution of the monomer sequence. Generally, these properties are understood to be averages of the different components, but recent work from the Olvera de la Cruz group has shown that the statistical distribution of random copolymers make them uniquely suited to form complexes with proteins, which have a heterogenous surface composed of hydrophilic, hydrophobic, and charged domains. This discovery allows us to develop novel and cost-effective techniques to enhance the properties of certain proteins, such as those with enzymatic functions, and increase their stability in demanding environments. The basic principles and potential applications of such techniques will be discussed.

*This work is funded by the Sherman Fairchild Foundation.
9:12AM F35.00005: Synthesis and Self-assembly of Saccharide-Polystyrene Hybrid Block Copolymers  MINJI SEO (Presenter), SHENG LI, KAIST — Oligosaccharide based block copolymers are a new class of hybrid polymers containing both natural and synthetic segments. Due to the large segregation strength between the hydrophilic saccharide block and the hydrophobic synthetic block, the resulting block copolymers are expected to microphase separate at small molecular weights, yielding ordered morphologies with sub-10nm feature sizes. In this contribution, a series of saccharide-containing diblocks and triblocks were prepared by combining maltotriose with polystyrene of different chain lengths. The polymer conjugates were synthesized via copper(I)-catalyzed 1,3-dipolar azide-alkyne cycloaddition of alkyne-functionalized maltotriose and azido-functionalized polystyrene. Additionally, bifunctional initiators were used to prepare triblocks of polystyrene center block and maltotriose end blocks. Despite the small size of maltotriose, the resulting block copolymers were found to microphase separate to form well-ordered microdomain structures. Their bulk morphologies as well as order-disorder transition behavior were examined to illustrate the complex phase behavior of these hybrid materials.

9:24AM F35.00006: Polyvinyl alcohol composite hydrogels containing mixtures of cellulose nanocrystals and chitin nanofibers*  CAMERON IRVIN, School of Materials Science and Engineering, Georgia Institute of Technology, CHINMAY SATAM, School of Chemical and Biomolecular Engineering, Georgia Institute of Technology, PAUL RUSSO, School of Materials Science and Engineering, Georgia Institute of Technology, JAMES CARSON MEREDITH, School of Chemical and Biomolecular Engineering, Georgia Institute of Technology, MEISHA SHOFNER (Presenter), School of Materials Science and Engineering, Georgia Institute of Technology — Among bio-based polymers, cellulose and chitin are abundant and available in a variety of forms, including nanofibers. Due to their anticipated mechanical properties and anisotropic structure, nanofibers of cellulose and chitin are desirable reinforcing fillers in polymers. These nanofibers are also dispersible in water, making them desirable as reinforcing fillers in polymer hydrogels as well. In this work, we have examined how cellulose nanocrystals (CNCs) and chitin nanofibers (ChNFs) may be used separately and as mixtures to affect the properties of poly(vinyl alcohol) (PVA) hydrogels. CNCs and ChNFs have negative and positive surface charges, respectively, providing opportunities for bonding between the nanofibers when used as mixtures and modifying the hydrogel properties further. The results of this work suggested that the types of networks formed were different with different filler types and these differences were observed through swelling behavior of the hydrogels and mechanical properties. Overall, these results demonstrate that nanoparticle mixtures may be used as effective reinforcements for polymer nanocomposites when compatible surface interactions are present between all the components.

Hierarchically Organized Structure of Electrospun Nanofibers from Computationally Designed Peptide Bundlemers

KYUNGHEE KIM (Presenter), CHRISTOPHER J. KLOXIN, Univ of Delaware, JEFFERY G SAVEN, University of Pennsylvania, DARRIN JOHN POCHAN, Univ of Delaware — Fiber materials made from natural or synthetic polymers can be used as high performance materials exhibiting high stiffness, strength, and/or elongation, all while being light weight. The ability to create a desired internal nanostructure with controllable molecular interactions in the fibers is paramount to a construction of new materials with unique structural features and a remarkable combination of high stiffness, strength, and elongation. Herein, peptides are computationally designed to self-assemble into coiled coil bundles that serve as supramolecular monomers, or “bundlemers”, to create a hierarchical structure for high performance nanofibers. The bundlemers have chemical functionality for desired covalent interactions between bundles to facilitate hierarchical chain growth that displays rigid-rod character. The rigid rods are employed to fabricate uniform nanofibers via electrospinning. The rod chains are observed to be aligned along the fiber axis due to their molecular rigidity and the solution flow during electrospinning process, which impacts the eventual mechanical properties of the nanofibers. The mechanical properties of electrospun rod fibers are investigated as a function of rod length and intra- or inter-chain interactions in the rod chains.

DOE DE-SC0019355

Chitin Nanocrystals confined to polymer microgels.

SUJIN LEE (Presenter), ELSA REICHMANIS, JUNG O PARK, MOHAN SRINIVASARAO, Georgia Inst of Tech — Chitin is the second most abundant polysaccharide after cellulose, which can be extracted from exoskeletons of crustaceans and also from cell walls of fungi and insects. Similar to cellulose nanocrystals, chitin nanocrystals can be isolated through acid hydrolysis and form cholesteric phase. We investigate chitin nanocrystals confined to pnipam microgels using microfluidics device. The twisted structure of chitin nanocrystals are preserved within the polymer spheres, as characterized by optical microscopy. The droplet radius, R of the microgels can be adjusted by changing the volumetric flow rate of oil phase in a microfluidics device. Interestingly, the fabricated microgels shows bipolar structure with the shape of prolate spheroids. They exhibit swelling-deswelling behavior upon temperature change along the axis of helix.
10:00AM F35.00009: Enhanced mechanical properties of fatty acid-derived thermoplastic elastomers through incorporation of ionic interactions* MEGAN ROBERTSON (Presenter), WENYUE DING, JOSIAH HANSON, Univ of Houston — Vegetable oils and their fatty acids are attractive resources for polymers, due to their worldwide abundance, yet the presence of long alkyl chains greatly impacts the resulting polymer properties. The incorporation of ionic interactions in the unentangled poly(n-alkyl methacrylate) midblock of a fatty acid-based thermoplastic elastomeric triblock copolymer was explored as a method of improving its mechanical properties. Poly(methyl methacrylate-b-(lauryl methacrylate-co-tert-butyl methacrylate)-b-methyl methacrylate), which exhibits low tensile strength and elongation at break, was modified by hydrolysis to form poly(methyl methacrylate-b-(lauryl methacrylate-co-methacrylic acid)-b-methyl methacrylate). The methacrylic acid group in the midblock was further neutralized with sodium hydroxide to introduce ionic crosslinks into the system. Increased relaxation time was observed by increasing ion and acid contents. The triblock copolymer mechanical properties were improved significantly by the incorporation of ionic interactions. Enhancement of mechanical properties was correlated with the relaxation time of the midblock.

10:12AM F35.00010: Characterizing Network Structure in Lignin-Based Hydrogel Composites for Aqueous Separations NICHOLAS GREGORICH (Presenter), JUNHUAN DING, MARK C. THIES, ERIC M DAVIS, Clemson University — Lignin-based hydrogels have garnered attention for use in a variety of aqueous separations as lignin is a sustainable, naturally abundant biopolymer with a high concentration of hydroxyl groups, which can be utilized as crosslinking sites during hydrogel fabrication. However, to date, widespread use of these materials is hindered by our limited understanding of how the addition of lignin alters the network structure of these composite hydrogels. Herein, lignin–poly(vinyl alcohol) (PVA) composites were synthesized using lignins of prescribed molecular weights (MWs) and low dispersity using two different crosslinking agents (CLA) – ammonium persulfate and glutaraldehyde. The permeability of various pollutants through the hydrated composites was measured via ultraviolet-visible spectroscopy, where penetrant permeability was found to depend on the MW of lignin and PVA, as well as the concentration of CLA utilized during membrane fabrication. In addition, poroelastic relaxation indentation was used to characterize both the mechanical and transport properties of the composites. Results from this work indicate that transport of pollutants through the composite hydrogels is governed by a combination of the network structure and strength of interaction between the pollutant and lignin.
MCKENZIE COUGHLIN (Presenter), JERRICK EDMUND, Chemical Engineering and Materials Science, University of Minnesota, S. PIRIL ERTEM, SVETLANA MOROZOVA, Chemistry, University of Minnesota, PETER SCHMIDT, Chemical Engineering and Materials Science, University of Minnesota, THERESA M REINEKE, Chemistry, University of Minnesota, FRANK S BATES, TIMOTHY LODGE, Chemical Engineering and Materials Science, University of Minnesota — Methylcellulose (MC) is a commercially relevant cellulose ether. As a water-soluble polymer, MC is used in a variety of applications from food to construction materials. Many applications exploit the thermoreversible gelation of MC at ca. 60 °C, which has been correlated with the formation of nanofibrils upon heating. Previously, we have shown that grafting poly(ethylene glycol) (PEG) chains onto MC modifies the fibril structure, including suppression of fibrils at high enough grafting densities. To expand our understanding of fibril formation, we have grafted poly(N-isopropylacrylamide) (PNIPAm) onto MC at various grafting densities. PNIPAm is water-soluble at room temperature, however, it displays a lower critical solution temperature at ca. 32 °C and phase separates upon heating. The chain conformation of PNIPAm-grafted MC was studied using dynamic and static light scattering as a function of temperature and grafting density. Cryogenic electron microscopy and small-angle X-ray scattering revealed changes in fibril structure and formation. Utilizing small-amplitude oscillatory shear, we characterized the change in modulus and gelation behavior. The effects of PNIPAm-grafting on MC gelation and fibril formation will be compared to the results obtained with PEG-grafted MC.

SUSAN KOZAWA (Presenter), ANNE WALKER, JONAH SCOTT-MCEAN, Case Western Reserve University, JEANETTE GARR, Youngstown State University, CHRIS FLASK, MICHAEL HORE, ALBERTO COSTA, GARY WNEK, Case Western Reserve University — Poly(acrylate) gels have been shown to exhibit electrical potentials in the range normally afforded by living cells. We have unexpectedly found that bathing poly(acrylate) gels in aqueous solutions of monovalent salts such as KH₂PO₄ in a narrow concentration range (ca. 8-16 mM) leads to a softening of gels without measurable volume changes. Moreover, electrical potentials of the gels in KH₂PO₄ solutions show an abrupt increase in gel potential concomitant with the mechanical softening transition. Magnetic resonance imaging experiments reveal an increase in water spin-spin relaxation time (T₂) at this range and small angle neutron scattering demonstrate a structural change at this transition, indicating increased water mobility due to a change in mesh size. This leads us to suggest additional considerations toward a more comprehensive theory of polyelectrolytes, namely ion site and affinity.

10:48AM F35.00013: Strain-Field Analysis of Subsonic and Supersonic Cracks in Filled Elastomers  THANH-TAM MAI (Presenter), KENJI URAYAMA, Kyoto Institute of Technology — In the present study, the transition in the characteristics of local crack-tip strain-field from the subsonic ($V/C_s < 1$) to supersonic ($V/C_s > 1$) cracks in filled elastomers is investigated, where $V$ and $C_s$ are crack-growth velocity and shear wave speed, respectively. The crack propagation of the specimens stretched by pure shear deformation is observed by a digital high-speed camera. The crack-tip strain-field is evaluated by the two-dimensional digital image correlation technique (DIC) on the basis of the captured speckle images. The critical behavior of the vertical strain field ($e_{yy}$) near the crack-tip is characterized by the exponent $\alpha$ in the power law, $e_{yy} \sim (1/r)^\alpha$, known as a crack-tip singularity field. The exponent $\alpha$ in the subsonic crack is constant and larger than those of the linear elastic fracture mechanics (LEFM, $\alpha = 0.5$) as well as weakly nonlinear fracture mechanics (WNLM, $\alpha = 1$). In contrast, the exponent $\alpha$ in supersonic crack significantly increases with an increase in the crack growth rate.

Session F36 DCOMP: Molecular Dynamics Ex Machina: Successes and Challenges 601/603 - Tag(s): Invited
Bayesian optimization is employed to build N-dimensional surrogate models for the energy or property landscapes and infer global minima. The models are iteratively refined by sequentially sampling DFT data points that are promising and/or have high information content. Representing heterogenous materials with compact chemical ‘building blocks’ allowed us to build in prior knowledge and reduce search dimensionality. The uncertainty-led exploration/exploitation sampling strategy delivers global minima with modest sampling, but also ensures visits to less favorable regions of phase space to gather information on rare events and energy barriers.

We applied this active learning scheme to study adsorption at the organic/inorganic interfaces: C\textsubscript{60} on TiO\textsubscript{2}(101) anatase and camphor on Cu(111). Global minima in 6 dimensions are identified with reasonable computational efficiency. BOSS produces chemically-intuitive adsorption energy landscapes that are parsed for local minima and the minimum energy paths between them, allowing us to extract complex barrier-related atomistic pathways. With a recent batch implementation for active learning, BOSS can make use of exascale computing resources to solve large-scale structural problems without sacrificing quantum-mechanical accuracy.

8:36AM F36.00002: Construction and simulation proofs of reliable high-dimensional neural network atomic potentials* [Invited] SATOSHI WATANABE (Presenter), KOJI SHIMIZU, The University of Tokyo, WENWEN LI, YASUNOBU ANDO, AIST, EMI MINAMITANI, Institute for Molecular Science, SEUNGWU HAN, Seoul National University — High-dimensional neural network atomic potentials (HDNNP) [1] has attracted attention because of their potential to achieve reliability and computational efficiency simultaneously. In this talk, we show our attempts to apply the HDNNP to several different topics, and discuss how to construct reliable HDNNP and verify the reliability through simulation proofs.
We show our results on Li ion diffusion in amorphous Li$_3$PO$_4$ [2] and thermal conductivities of wurtzite GaN and silicon crystals [3]. In both cases, we achieved good agreement with calculations within the density functional theory. Then we discuss the atomic energy mapping inferred by HDNNP [4]. We show that the energy mapping can be improved by choosing the training set carefully and monitoring the atomic energy during the training procedure. In addition, we will also touch on the HDNNP to examine the atomic structures of a complex four-element system, Au/Li$_3$PO$_4$ interfaces [5].

9:12AM F36.00003: Embedding physics in machine learning potentials [Invited] GÁBOR CSÁNYI, Department of Engineering, University of Cambridge, ALBERT BARTOK (Presenter), Warwick Centre for Predictive Modelling, School of Engineering, University of Warwick — The last decade has seen an expansion in machine learning methods applied to atomistic modelling problems. Utilising the flexible functional form allowed by different flavours of machine learning approaches and thanks to the abundance of electronic structure data, it is now possible to fit highly predictive potential energy surfaces. However, transferability of these models is often limited, and predictive accuracy may only be expected in structural domains where the training data is concentrated. In the case of complex materials, where the accessible configurational space is significantly larger, data requirements could be prohibitive, and there is a need to place constrains on the interaction model. In this talk, I will discuss machine learning potentials in a Bayesian framework, and how physical knowledge and intuition can be embedded in the Bayesian prior of the model.
Automated training of machine learned potentials with Bayesian active learning

JONATHAN VANDERMAUSE (Presenter), YU XIE, LIXIN SUN, JIN SOO S LIM, STEVEN B TORRISI, SIMON BATZNER, Harvard University, ALEXIE KOLPAK, Massachusetts Institute of Technology, BORIS KOZINSKY, Harvard University — Machine learned interatomic potentials are often manually trained and restricted to single-component and nonreactive systems, severely limiting the practical application of these models. We present an adaptive Bayesian inference method for automating the training of multi-element interatomic potentials using structures drawn “on the fly” from molecular dynamics simulations. Within an online active learning algorithm, the internal uncertainty of a Gaussian process (GP) regression model is used to decide whether to accept the model prediction or to perform a first principles calculation to augment the training set of the model and reoptimize its hyperparameters. Model uncertainties are derived from the variance of the predictive posterior distribution of the GP, which is shown to correlate with true model error on independent test sets. The GP models are based on low-dimensional, explicitly multi-element two- and three-body kernels that can be mapped onto highly efficient cubic spline models suitable for large scale molecular dynamics simulations. Applications to a range of single- and multi-element systems will be discussed, including vacancy and adatom migration in Aluminum, fast-ion diffusion in AgI, and surface segregation in Pd/Ag alloys.

Machine-learning interatomic potentials: a story about how a Big Data approach compensates for our incomplete understanding of interatomic interaction

ALEXANDER SHAPEEV (Presenter), Skolkovo Institute of Science and Technology — Machine learning, an approach to create models based on large amounts of data, is transforming many fields of research. This approach allows us to compensate for our incomplete understanding of a phenomenon by incorporating big data into a model. In my talk I will illustrate how this ideology works in the field of models of interatomic interaction.

Namely, in the first part of my presentation I will give a brief introduction to machine-learning potentials and present some of their success stories. The second part will be devoted to methodological foundations of machine-learning potentials and their successes. In particular, I will formulate the problem of construction of an interatomic potential as a model reduction problem with respect to a quantum-mechanical model (such as DFT). I will then discuss what modeling assumptions are made in classical potentials, identify which ones cause uncontrollable errors, and show how machine learning helps to lift some of those assumptions while still benefiting from physical knowledge. I will conclude by discussing the existing challenges related to those modeling assumptions that are difficult to lift or those cases in which common assumptions fail.

8:00AM F37.00001: The flocking theory: The early developments and a new perspective
[Invited] YUHAI TU (Presenter), IBM Tj Watson Research Center — In this talk, I will first describe some of the "accidental" events over 25 years ago that led to the early developments of the flocking theory. I will then discuss a possible new perspective on the flocking theory by looking at the non-equilibrium thermodynamics of collective motion in active matter.

8:36AM F37.00002: Title: Birth, Death, and Flight: the hydrodynamics of Malthusian flocks
[Invited] JOHN TONER (Presenter), Univ of Oregon — Abstract:

I'll present the hydrodynamic theory of ` `Malthusian Flocks": moving aggregates of self-propelled entities (e.g., organisms, cytoskeletal actin, microtubules in mitotic spindles) that reproduce and die. Long-ranged order (i.e., the existence of a non-zero average velocity \( \langle \vec{v}(\vec{r}, t) \rangle \neq \vec{0} \)) is possible in these systems, even in spatial dimension \( d = 2 \). Their spatiotemporal scaling structure can be determined exactly in \( d = 2 \); furthermore, they lack both the longitudinal sound waves and the giant number fluctuations found in immortal flocks. Number fluctuations are very \{it persistent\}, and propagate along the direction of flock motion, but at a different speed. I'll also present recent results for the three dimensional version of this problem, which required the first full blown dynamical renormalization treatment of a flocking system in its ordered phase.

9:12AM F37.00003: Dynamics of the Outer Solar System: from Neptune to Planet Nine
[Invited] TALI KHAIN (Presenter), Physics, University of Michigan, University of Chicago — The Kuiper belt, found beyond the orbit of Neptune, consists of a population of small, icy bodies that orbit the Sun. Due to perturbations from the giant planets (Jupiter, Saturn, Uranus, Neptune), the orbits of these objects slowly evolve with time. In this talk, we will analyze the orbital dynamics of the Kuiper belt objects (KBOs) both with numerical simulations and with a theoretical Hamiltonian approach. We will discuss the structure of the outer Solar System and focus on the most extreme sub-population of objects: the long-period high eccentricity class. The orbits of these extreme KBOs all appear to point in the same direction in physical space; this anomalous signal cannot be explained by the currently known eight-planet Solar System. In order to understand their origin and dynamics, we introduce the hypothesized Planet Nine to the distant Kuiper belt. We find that the presence of Planet Nine allows for two stable populations of objects - the aligned and anti-aligned KBOs - in agreement with observations. We will discuss the mechanisms that lead to this stability, and focus on a fascinating process called resonance hopping, in which a KBO rapidly transitions from one resonance to another with Planet Nine. By tying together studies of observed KBOs with more general analyses of the evolution of synthetic test particles, we elucidate the dynamics of the outer Solar System in and out of the Planet Nine context.
9:48AM F37.00004: Irwin Oppenheim Award talk: What is the simplest model of an amorphous solid? [Invited] ERIC DEGIULI (Presenter), Ryerson Univ — From glasses and emulsions to colloids and granular matter, amorphous solids show surprising universality in correlations, vibrational properties, and rheology. It has become increasingly clear that constraints of mechanical equilibrium control these universal features. Is there a simple model, analogous to the Debye model for crystals, able to explain this? I will review attempts to answer this question from jamming, large-dimension, and field-theoretic approaches, and argue that the latter is useful and parsimonious. Future challenges and gaps in understanding will be outlined.

10:24AM F37.00005: Something from (almost) nothing: complex lessons from simplicity* [Invited] NIGEL GOLDENFELD (Presenter), University of Illinois at Urbana-Champaign — I describe the use of minimal renormalization-group inspired/justified models in non-equilibrium statistical physics and biology. Using examples chosen from my own work in pattern formation, turbulence and biology, I point out that minimal models are able to make specific parameter-free predictions of appropriately-chosen experimental quantities, an outcome of universality in somewhat surprising settings. I argue that these considerations account for the unreasonable effectiveness of theoretical physics in describing seemingly complex phenomena.

*My work has been continuously funded by the National Science Foundation for 34 years, and by other agencies of the US government including NASA, the Department of Energy and the National Institutes of Health. I am grateful for their long-term support.

Tuesday, March 3, 2020 8:00 AM - 10:24 AM

Session F38 FHP DCOMP: Computation in the History of Physics 607 -

8:00AM F38.00001: Physics in the History of Computing: A Case Study from NSF [Invited] PETER FREEMAN (Presenter), Georgia institute of Technology — The histories of computation and of physics since the 1930s have had an essential co-dependency with each other. Without the most powerful computers and optical networks, many of the most important investigations in physics would be impossible. At the same time, the advancement of computer science and its applications that pervade modern life would also be impossible without the advancements in physics. A recent book, Peter A. Freeman, W. Richards Adrion, and William Aspray, Computing and the National Science Foundation, 1950-2016: Building a Foundation for Modern Computing (ACM Books, 2019, 407 pp.) yields some interesting examples of this co-dependency and areas for further historical research.
8:36AM F38.00002: On the status of Landauer's principle [Invited] KATHERINE ROBERTSON (Presenter), Univ of Birmingham — Maxwell's demon is a creature who cunningly violates the second law of thermodynamics. In what sense is such a demon possible? Whilst thermodynamics legislates against such a creature, the demon looks eminently possible according to the underlying classical or quantum dynamics: Poincare's recurrence theorem and Loschmidt's reversibility objection reveal that entropy can decrease in certain situations.

The orthodoxy is that Maxwell's demon is vanquished by Landauer's principle, according to which there is an entropy cost to reset the demon's memory - a vital step in the cyclic process that supposedly leads to a violation of the second law. But the status of Landauer's principle is controversial: some take it as obviously true, others (such as John Norton) have criticised the proofs of this principle.

In this talk, I clarify the status of Landauer's principle. First I discuss which assumptions are required to establish Landauer's principle, and argue that establishing to which theory (thermodynamics, statistical mechanics or quantum mechanics) these principles belong reveals the status of Landauer's principle. I then consider one of Norton's counterexamples to Landauer's principle, and discuss how it depends on certain views about the physical implementation of computation.

9:12AM F38.00003: Simulation Model Skill in Cosmology. [Invited] ERIC WINSBERG (Presenter), Univ of South Florida — What role can/could simulation play in supporting, puzzle-solving, modifying, disconfirming, or falsifying ΛCDM and its competitors? I review some of the problems cosmologists have solved or hope to solve using computer simulation, and examine some of problems and successes that have emerged. I draw some conclusions regarding the kind of simulation model skill we should expect to find in Cosmology.

9:48AM F38.00004: Cosmology in Silico [Invited] MARIE GUEGUEN (Presenter), University of Pittsburgh — Simulations play an ineliminable role in contemporary cosmology. Given the enormous range of processes involved—from stars forming to clusters of galaxies and cosmic filaments—and their non-linear nature, only numerical simulations can tell us what the standard cosmological model implies for structure formation. Simulations are thus indispensable to extract predictions from models, but also to supplement sparse or non-existing observations, and to help designing the observational surveys.

This ubiquity of simulations in cosmology raises an important concern. Indeed, a few astrophysicists have insisted that simulations suffer from numerical artefacts that none of the traditional methods to assess their reliability have successfully detected. These artefacts significantly impact our ability to track the logical consequences of the physical model implemented. As a result, when simulations fail to reproduce observations, there is no tool available to determine whether this discrepancy stems from numerical artefacts or constitutes a genuine failed prediction, and thus a motivation to revise our models. Yet, not only this concern has been neglected, but the race to an ever-increased resolution and more realistic simulations have made the problem even more complex. In this talk, I present a new method for evaluating the reliability of cosmological simulations, based on the reasoning of these astrophysicists who have contested traditional procedures for verifying simulations.
8:00AM F39.00001: **Nonlinear optics from first-principles real-time approaches** [Invited] MYRTA GRÜNING (Presenter), Atomistic Simulation Centre, Queen's University Belfast, CLAUDIO ATTACCALITE, Centre Interdisciplinaire de Nanoscience de Marseille, CNRS/Aix-Marseille Université — In the past decades, many-body approaches based on the GW approximation and the Bethe-Salpeter equation have become state-of-the-art for calculating optical absorption in solids and nanostructures. In this talk, I’ll first present a real-time approach derived from the non-equilibrium Green’s function, that allows extending the GW+BSE approach beyond the linear regime.[1,2] Using this approach, I’ll address the importance of many-body effects and in particular of excitonic effects for nonlinear optical properties.[3] For example, I’ll look at the case of single-layer monochalcogenide whose strong Second Harmonic Generation cannot be reproduced within the independent-particle approximation.[4] In the second part of the talk, I’ll then discuss the possibility of a real-time approach based on time-dependent density-functional theory, that can describe excitonic effects.[5]

8:36AM F39.00002: **Exciton bandstructure in carbon nanotubes from many-body perturbation theory** DANA NOVICHKOVA (Presenter), Materials and Interfaces, Weizmann Institute of Science, DIANA QIU, Mechanical Engineering and Materials Science, Yale University, SIVAN REFAELY-ABRAMSON, Materials and Interfaces, Weizmann Institute of Science — Understanding exciton decay processes and lifetimes in solid-state materials is of great interest, with emerging applications such as material characterization and energy conversion and storage. A predictive theoretical assessment of the involved underlying interaction mechanisms is, however, highly challenging. A computational scheme that supplies reliable excited-state properties in crystals is many-body perturbation theory within the GW approximation and the Bethe-Salpeter equation (BSE) approach (GW-BSE). This method allows a predictive evaluation of exciton wavefunctions and excitation energies, and recently also exciton bandstructures. In this study, we explore the excitonic bandstructure of a quasi 1D system – single wall carbon nanotubes (SWCNTs), a well-examined material due to its unique electronic properties and application in optoelectronic devices. We further explore the relation of the exciton dispersion to excitonic decay processes.

Exciton and Spin Dynamics for Quantum Defects in Two-dimensional Materials from First-principles

YUAN PING (Presenter), University of California, Santa Cruz — Spin defects in 2D materials such as ultrathin hexagonal boron nitride (hBN) have been found to be promising single-photon emitters and potential candidates for qubits. However, first-principles prediction of accurate defect properties in 2D materials remains challenging, mainly because of the highly anisotropic dielectric screening in 2D materials and strong many body interactions. This work shows how we solve the numerical convergence issues for charged defect properties in 2D materials at both the DFT and many body perturbation theory (GW/Bethe-Salpeter equation), and how we tackle the complex many body interactions including electron-electron, electron-phonon and defect-excitons for the excited state dynamics of spin defects in 2D materials. We are also developing first-principles spin dynamics through Lindblad dynamics for open quantum systems. With our methods, we will design spin defects that have deep defect levels, weak electron-phonon coupling, high radiative recombination rates, and long spin relaxation and coherence time as future materials platforms for quantum information technologies.

This work was funded by NSF DMR-1760260.

Local Field Effect on Non-local Dielectric Screening of Two-Dimensional Interface Systems: A First-principles Study

CHUNHAO GUO (Presenter), JUNQING XU, University of California, Santa Cruz, USA, DARIO ROCCA, University of Lorraine, LPCT, UMR 7019, 54506 Vandœuvre-lès-Nancy, France, YUAN PING, University of California, Santa Cruz, USA — Two-dimensional (2D) materials have provided platforms for exotic physics and emerging applications by forming van-der Waals interfaces. Non-local dielectric screening by substrates play an important role in modifying the quasiparticle properties of these interface systems. While several studies have been performed for the substrate screening of 2D materials, the underlying approximations and the connection between different methods have not been investigated in detail. We derived the effective polarizability of the interfaces from each monolayer sub-system, and showed its equivalence to sum over irreducible polarizability at the Random Phase Approximation level. We used this method to calculate prototypical 2D interface systems (heterojunctions and bilayers) and compared with explicit calculations. We compared different existing methods and discussed the local field effect on quasiparticle energies and absorption spectra. Our study shows good consistency between single layer calculations with effective interface screening and explicit interface calculations, and provides careful evaluation of approximations involved in studying substrate screening and interface quasiparticle properties.

9:12AM F39.00005: Microscopic Theory of Plasmons in Substrate-supported Borophene* 
ANUBHAB HALDAR (Presenter), Boston Univ, CRISTIAN CORTES, PIERRE DARANCET, Center for Nanoscale Materials, Argonne National Laboratory, SAHAR SHARIFZADEH, Boston Univ — Two-dimensional boron, or borophene, is a metallic monolayer material which hosts low-loss, high-confinement, visible light plasmons, with possible applications in nanoplasmonic devices. In contrast with graphene, borophene cannot be exfoliated and has been synthesized on a variety of metallic substrates. In this talk, we present first-principles density functional theory calculations of the dielectric and plasmonic properties of borophene grown on Ag(111). We systematically investigate the linear response and the momentum-dependent polarizability of borophene as a function of its proximity to the metallic substrate. Our calculations indicate that the plasmons in borophene are damped by the substrate, which we explain via a simple electrodynamic model of coupled polarizabilities between the monolayer and substrate. Using this model, we predict the plasmonic properties of borophene on a variety of substrates that minimize plasmon damping.

* S.S. and A.H acknowledge funding from DOE BES Award #DE-SC0018080. This material is based upon work supported by LDRD funding from Argonne National Laboratory under Contract No. DE-AC02-06CH11357. Use of the Center for Nanoscale Materials was supported by DOE under Contract No. DE-AC02-06CH11357.

ARIELLE COHEN (Presenter), KIRK LEWIS, TIANLUN HUANG, SAHAR SHARIFZADEH, Boston Univ — Germanium Selenide (GeSe) and other Group IV monochalcogenides are van der Waals-bonded layered materials with potential applications in sensing, solar energy and spintronics. Importantly, their band gaps can be tuned via strain, doping, and chemical modification. Due to the reduced dimensionality and reduced screening environment in the monolayer, these modifications have a significant impact on the optoelectronic properties. We apply density functional theory (DFT) and many-body perturbation theory to understand the electronic and optical properties of point vacancies in monolayer GeSe. We find that a Selenium vacancy in the -2 charge state induces mid-gap “trap states,” which strongly localize the electron and hole density. These trap states result in a sharp optical absorption peak below the predicted pristine optical gap and a localized exciton wavefunction around the defect. Overall, these results suggest that the vacancy is a strong perturbation to the system, demonstrating the importance of considering defects in the context of materials discovery and device design.

* The authors acknowledge funding support from the U.S. Department of Energy, Office of Science, Award #DE-SC0018080 and computational resources from DOE NERSC and NSF-XSEDE.
9:36AM F39.00007: Investigating the Role of Electron-Phonon Interactions and Reduced Dimensionality on Optical Excitations in Monolayer GeSe*  
TIANLUN HUANG (Presenter), KIRK LEWIS, ARIELLE COHEN, SAHAR SHARIFZADEH, Boston Univ — Two-dimensional (2D) van der Waals-bonded layered materials are promising as inexpensive, light-weight solar energy conversion materials. Better understanding the role of electron-phonon interactions in 2D will be necessary for understanding the optical properties of this class of materials. Here, we use first-principles theory to investigate the role of electron-phonon interactions on the optical absorption spectrum of monolayer germanium selenide GeSe, a direct gap 2D semiconductor with promising optoelectronic properties. We utilize density functional theory, density functional perturbation theory, and many-body perturbation theory to study both bulk and monolayer GeSe. We determine that the optical gap at room temperature is lower than that of the zero temperature for both systems. For the bulk, an indirect gap semiconductor, this reduction is mainly due to phonon-assisted transitions. For the monolayer, we attribute the reduced gap to the localization of the excited-state in the presence of phonons. The significant influence of electron-phonon interactions in the monolayer suggests that this phenomenon should be better understood for 2D material technology.

*We acknowledge funding from U.S. Department of Energy, Office of Science, Award #DE-SC0018080

9:48AM F39.00008: Dielectric embedding GW for weakly coupled molecule-substrate interfaces*  
ZHENFEI LIU (Presenter), Department of Chemistry, Wayne State University — Molecule-substrate interfaces are ubiquitous in many areas of nanoscale materials science. Accurate characterization of their electronic structure from first principles is key in understanding material properties. Although the first-principles GW approach is state-of-the-art and can yield accurate quasiparticle energy levels and interfacial level alignments that are in agreement with experiments, it is computationally challenging for large-scale interfaces. In this work, we develop a dielectric embedding approach based on GW, which significantly reduces the computational cost of direct GW for interfaces without sacrificing accuracy. We perform explicit GW calculations only in the simulation cell containing the molecular adsorbate, in which the dielectric effect of the substrate is effectively embedded. The embedding of the dielectric environment is made possible via a real-space truncation of the Kohn-Sham polarizability. Here, we focus on the interfacial level alignments, i.e., relative positions between molecular frontier orbital resonances and the Fermi level of the substrate, at weakly coupled molecule-substrate interfaces. We demonstrate our approach using a few interfaces of experimental interest.

*Computational resources are provided by NERSC and Argonne National Laboratory.
KEIAN NOORI (Presenter), FENGYUAN XUAN, SU YING QUEK, Natl Univ of Singapore — As the technological applications of 2D material-based electronics continue to rise, an understanding of the physical underpinnings of the energy barriers between metal-2D material contacts becomes critically important. Experimentally, these interfaces are often found to be controlled by Fermi-level pinning, which prevents the tuning of Schottky barrier heights by the modification of the contact metal work function. Theoretically, the high computational cost of these systems has largely restricted first principles studies to DFT-level calculations. The effects of dielectric screening, which are important even in atomically thin 2D materials$^1$, are therefore also ignored. Moreover, the small unit cells considered do not allow for the inclusion of defects, which can affect the energy-level alignment at the interface.

In this work we use the newly-developed XAF-GW approach$^2$ to study large supercells at the many-body GW level, thus including the full effects of dielectric screening. We examine the origin of the Schottky barrier heights of metal-2D material interfaces, including the effects of dielectric screening, structural reconstruction, and defects.

NOCONA SANDERS (Presenter), EMMANOUIL KIOUPAKIS, University of Michigan — Given the successful synthesis of 2D GaN and investigations into the properties of freestanding 2D nitrides, heterostructures of these materials are now of particular interest. Extreme quantum confinement is a viable method to shift light emission to shorter wavelengths, but in 2D nitrides this is counteracted by the quantum-confined Stark shift due to the strong inherent polarization perpendicular to the 2D plane. We report the electronic and optical properties of 2D BN, GaN, AlN, and InN in various stacking orientations, such that the electric fields are either aligned or anti-parallel in two possible configurations. We employ density functional theory and quasiparticle corrections with the GW method, as well as the Bethe-Salpeter Equation, to derive accurate band structures, exciton binding energies, and luminescence energies. Through understanding how the stacking arrangement influences the underlying electronic and optical properties, critical insight will be gained in how to improve 2D III-nitride-based optoelectronics through accessing the additional degree of freedom provided by polarization.

*This work was supported by the NSF ECCS-CDS&E program (1607796). Computational resources were provided by the DOE NERSC facility under Contract No. DE-AC02-05CH11231.
10:24AM F39.00011: Optical trap for two-dimensional excitons* HIROKI KATOW (Presenter), AIST, RYOSUKE AKASHI, University of Tokyo, YOSHIYUKI MIYAMOTO, AIST, SHINJI TSUNEYUKI, University of Tokyo — For its potential optical controllability as quantum degrees of freedom, the exciton in two-dimensional system has attracted much attentions. In this presentation, we propose an optical trapping technique for the exciton. Exploiting the energy shift mechanism of excitonic system coupled to the electromagnetic field, spatial confinement potential can be implemented. The dimensionality and symmetry of the potential can be dynamically tunable. We performed an \textit{ab initio} calculation of the excitonic states in graphane, a two-dimensional wide gap semiconductor with $D_{3d}$ symmetry, based on GW+BSE method by using \textit{BerkeleyGW} package. The lowest excitonic state belongs to $E_u$ representation, followed by $E_g$ and $A_{2g}$ excitons of which energy levels are 500meV and 650meV apart from $E_u$ exciton, respectively. Two- and three-level systems can be implemented by coupling these levels with optical fields. We will report the possible depth and polarization dependency of the potential by applying nearly infrared laser light.

*This work is supported by a NEDO project “Development of advanced laser processing with intelligence based on high-brightness and high-efficiency laser technologies (TACMI project) and the use of the Supercomputer Center facilities, the ISSP the University of Tokyo.

10:36AM F39.00012: Accurate and approximative many-body methods for optical gap of semiconducting 2D materials* FRANTISEK KARLICKY (Presenter), Department of Physics, University of Ostrava — Many-body GW approximation and Bethe-Salpeter equation (BSE) are considered as state-of-the-art methods for reliable prediction of quasiparticle (QP) and optical gaps of bulk materials, respectively. On the other hand, GW and BSE methods are still computationally challenging and its usage for a larger supercell is almost unfeasible. We show which factors are important to obtain accurate QP and optical gaps by GW+BSE approach and we evaluate the magnitudes of such factors [1-3]. We also show that several computationally cheap approximations based on time-dependent DFT can be used as accurate alternative to GW+BSE approach and promising applications on selected vdW heterostructures are demonstrated [3-4].

The Zeeman effect of excitons in two-dimensional transition metal dichalcogenides (TMDs) has attracted much recent attention. A g-factor can be associated with the valley splitting of the band structure in the presence of a weak out-of-plane magnetic field. Experimentalists have measured g-factors of -4 and -16 for excitons in monolayer and twisted bilayer TMDs. Theoretical interpretations of the g-factors have largely focused on monolayer TMDs, relying on a phenomenological model or a k.p model. The phenomenological model assumes that the g-factor is a sum of orbital, spin and valley terms, while the k.p model uses effective masses extracted from tight-binding calculations. Here, we start from the Luttinger-Kohn approximation to treat the magnetic field as a perturbation in a periodic system, and show that the g-factor cannot be written as a sum of only orbital, spin and valley terms. We compute the g-factors for TMD materials using density functional theory (DFT) and include self-energy corrections within many-body perturbation theory (MBPT). Using these results, we comment on the exciton g-factors measured in both monolayer and twisted bilayer TMDs, and show that the MBPT results agree better with experiment than DFT. The effects of spin-orbit coupling are also discussed.

Session F40 DCOMP DCMP DAMOP DMP: Building the bridge to exascale: applications and opportunities for materials, chemistry, and biology IV 705 - James Belak, Lawrence Livermore Natl Lab - Tag(s): Focus
8:00AM F40.00001: Towards Exascale Electronic Structure and Quantum Transport Calculations [Invited] JERRY BERNHOLC (Presenter), North Carolina State University — The development of robust, adaptive software and algorithms that can fully exploit exascale capabilities and future computing architectures is critical to designing advanced materials and devices with targeted properties. We have developed an open-source code that discretizes the DFT equations on real-space grids that are distributed over the nodes of a massively parallel system via domain decomposition. Multigrid techniques are used to dramatically accelerate convergence while only requiring nearest-neighbor communications. The real-space multigrid (RMG) code achieves full plane wave accuracy and scales from desktops and clusters to supercomputers consisting of ~200k cores and 20k GPUs, including the Cray XE-XK systems and the new IBM-NVIDIA pre-exascale Summit. Multilevel parallelization with MPI, threads and/or Cuda/HIP programming enables adaptation to future exascale supercomputers. RMG is distributed via www.rmgdft.org, with over 3,800 downloads do date. Advanced functionalities are provided through interfaces to other codes, including QMCPACK, BerkeleyGW, Phonopy, and ALAMODE. RMG is also being used for high throughput vibrational analysis of large systems at the Spallation Neutron Source. We will also describe the non-equilibrium Green's function module based on variationally-optimized localized orbitals, by which quantum transport properties can be studied for devices containing tens of thousands of atoms with full DFT accuracy. For a system with ten thousand atoms, our initial implementation scales linearly from 100 to 1000 nodes on Summit, already gaining ~4x speed-up from GPUs over CPU-only calculations. Several applications will be described as time permits, including a nanocircuit that could potentially enable electrical sequencing of DNA, and a novel experimentally realizable graphene-nanoribbon-based negative differential resistance device.

8:36AM F40.00002: Towards first-principles design of quantum devices JACEK JAKOWSKI (Presenter), Oak Ridge National Lab, JERRY BERNHOLC, North Carolina State University, MINA YOON, DAVID LINGERFELT, Oak Ridge National Lab, WENCHANG LU, EMIL BRIGGS, North Carolina State University — With the Moore's Law in high-performance computing approaching limits, future progress relies on harnessing quantum effects. Modeling quantum behavior at device scale requires an exascale computer and software that fully utilizes its extraordinary capabilities. Much of current research exploring future directions for nanoscale electronics is focused on two-dimensional materials. Evaluation of future nanodevices is very difficult and it it requires simulations involving thousands of atoms. Advanced quantum-mechanical simulations can be used to develop novel device concepts and identify the appropriate combinations of atomic constituents and nanoscale structures, thereby radically accelerating progress. We discuss the implementation of time-dependent electron dynamics in the real-space multigrid (RMG) density functional theory software package. The use of multiresolution grids permits real-space description of the electronic structure of systems comprised of hundreds-to-thousands of atoms, allowing atomistic description of systems approaching realistic device scales that can include arbitrary defects/impurities. Some results for quantum materials are presented that we believe could be the focus of future quantum computing and quantum information technologies.
GPU-Acceleration of the ELPA2 Distributed Eigensolver for Applications in Electronic Structure Theory*  
VICTOR YU (Presenter), Department of Mechanical Engineering and Materials Science, Duke University, JONATHAN MOUSSA, The Molecular Sciences Software Institute, VOLKER BLUM, Department of Mechanical Engineering and Materials Science, Duke University — The solution of eigenproblems is often a key computational bottleneck that limits the tractable system size of electronic structure theory. For large systems, these eigenproblems can easily exceed the capacity of a single computer, thus must be solved on distributed-memory parallel computers. The ELSI library facilitates large-scale electronic structure calculations by providing a unified interface to various fast and scalable eigensolvers and density matrix solvers, including the EigenExa, ELPA, libOMM, NTPoly, PEXSI, and SLEPc libraries. The ubiquitous adoption of hybrid CPU-GPU nodes in supercomputing opens up new opportunities to accelerate electronic structure calculations. We here present GPU-oriented optimizations of the ELPA two-stage tridiagonalization eigensolver (ELPA2). On top of its existing cuBLAS-based GPU offloading, we add a CUDA kernel to speed up the back-transformation of eigenvectors, which was known as the main bottleneck of the two-stage tridiagonalization algorithm. CPU, GPU, and MPI activities are overlapped wherever possible. Robust choices that maximize the GPU compute intensity are identified. We demonstrate the performance of this GPU-accelerated eigensolver by a set of benchmark calculations.

*This work is supported by NSF under grant number 1450280.

Driving exascale computational science with AiiDA  
SEBASTIAAN HUBER ( Presenter), GIOVANNI PIZZI, NICOLA MARZARI, Ecole Polytechnique Federale de Lausanne — The ever-growing availability of computational power and sustained development of advanced computational methods have contributed much to recent scientific progress. This progress presents new challenges regarding the sheer amount of calculations and data that has to be managed.

Next-generation exascale computing infrastructures will harden these challenges and we believe will require automated and scalable solutions.

Therefore, we have developed a comprehensive, robust, open source, high-throughput infrastructure AiiDA (http://aiida.net) dedicated to address the challenges in automated workflow management and data provenance storage.

We discuss how AiiDA's engine can now sustain throughputs of ~100’000 processes/hour, while automatically storing full data provenance.

The provenance is stored in relational database that makes the data queryable, traversable, and directly enables high-performance data analytics.

Any simulation software can be interfaced to AiiDA via its plugin system, and AiiDA's workflow language provides advanced automation and error handling features, as we demonstrate through one of our high-throughput projects.

We highlight how the resulting data can be disseminated by and to the wider community in a FAIR way on the Materials Cloud (http://materialscloud.org).
**9:12AM F40.00005: DMFTwDFT: A free-license DMFT package interfaced with various DFT implementations**

HYOWON PARK (Presenter), VIJAY SINGH, Univ of Illinois - Chicago, UTHPALA HERATH, West Virginia University, BENNY WAH, XINGYU LIAO, Univ of Illinois - Chicago, ALDO H ROMERO, West Virginia University — The electronic and structural characterization of strongly correlated materials (SCMs) is one of the most difficult problems in computational materials science. Dynamical Mean Field Theory (DMFT) has been successful in treating local many-body effects of correlated orbitals in SCMs, particularly when it is combined with density functional theory (DFT). In this talk, we present an open-source computational package (DMFTwDFT) combining DMFT with various DFT codes interfaced to a Wannier90 package for adopting maximally localized Wannier functions as local orbitals to describe a correlated subspace. We also provide the library mode for computing a DMFT density matrix such that our package can be efficiently linked to various DFT codes and achieves the charge-self-consistency within DFT+DMFT loops. We used our code for the study of well-known correlated materials, namely LaNiO3, SrVO3, and NiO to compute the density of states, the band structure, the total energy, the atomic force, and the Fermi surface within DFT+DMFT, and also compared our results to those obtained from other DFT+DMFT codes.

*This work is supported by the NSF SI2-SSE Grant 1740112.*

**9:24AM F40.00006: Scaling and Performance of Real-Space Electronic Structure Calculations on Exascale Architectures**

EMIL BRIGGS (Presenter), WENCHANG LU, JERRY BERNHOLC, North Carolina State University — Electronic structure calculations are hard to scale on massively parallel systems, and these challenges are compounded on CPU-GPU exascale architectures. Real-space formulations enable easy parallelization via domain decomposition, which has been implemented in our open-source real-space multigrid code (RMG). RMG has been designed to perform well on leading-edge supercomputers from inception. However, scaling to extreme sizes and to distributed multi-CPU-GPU architectures requires careful consideration of data distribution and flow, including inter-node transfers as well as between CPUs and GPUs located on the same node. The large mismatches between CPU and GPU clock speeds and FLOP rates provides additional constraints as well as optimization opportunities. We will discuss efficient and scalable implementation of distributed data flow and key electronic structure algorithms on exascale class machines in RMG, as well as methods for addressing MPI scalability constraints and data bottlenecks. RMG source code and build scripts for pre-exascale Summit, Cray XE-XK, clusters, Linux, Windows, and MacOS workstations are available at [www.rmgdft.org](http://www.rmgdft.org) together with help files and examples.
9:36AM F40.00007: From LSMS to MuST: Large scale first principles materials calculations at the exascale*  
MARKUS EISENBACH (Presenter), XIANGLIN LIU, Oak Ridge National Lab,  
KHORGOLKHUU ODBADRAKH, University of Tennessee, YANG WANG, Pittsburgh Supercomputing Center, Carnegie Mellon University — We present recent advances in our Locally-selfconsistent Multiple Scattering (LSMS) code for scalable first principles density functional calculations of materials. A fundamental science drivers for large scale calculations is the need to understand materials beyond periodic crystalline lattices. Due to the large simulation cells of many thousands of atoms needed to describe complex electronic and magnetic ordering, defect states or disorder in alloys, the cubic scaling of traditional first principles methods has prevented direct first principles calculations. The real space formalism of LSMS enables calculations for $O(100,000)$ atom. In preparation for exascale systems, we are extending the use of accelerators to the calculation of forces and embedding methods for disordered systems. We will present results and performance measurements for defects in high entropy alloys and non-collinear magnetism in disordered systems. The computational capabilities will be available in our Multiple Scattering Theory suite (MuST) [https://github.com/mstsuite]

*Research supported in parts by the Office of Science of DOE and by the NSF Office of Advanced Cyberinfrastructure and the Directorate of Mathematical and Physical Sciences. It used resources of the Oak Ridge Leadership Computing Facility.

9:48AM F40.00008: Mixed precision sampling of quantum states of matter*  
THOMAS MAIER (Presenter), Oak Ridge National Laboratory, GIOVANNI BALDUZZI, URS R HAEHNER, ETH Zürich, YING WAI LI, Los Alamos National Laboratory, ARGHYA CHATTERJEE, ED D'AZEVEDO, Oak Ridge National Laboratory — Monte Carlo simulations are widely used throughout all areas of science. In materials science, they provide an important framework to unravel the mechanisms that give rise to complex behavior and different quantum states of matter. The DCA++ code is a high-performance research application that solves quantum many-body, materials problems with a cutting edge quantum Monte Carlo based dynamic cluster approximation (DCA). Here we discuss how mixed precision arithmetics finds a natural home in statistical sampling based Monte Carlo, and how it is being used in DCA++ to boost performance on ORNL’s Summit supercomputer.

*This work was supported by the Scientific Discovery through Advanced Computing (SciDAC) program funded by U.S. Department of Energy, Office of Science, Advanced Scientific Computing Research and Basic Energy Sciences, Division of Materials Sciences and Engineering.
Towards finite-temperature tensor network simulations of the two-dimensional Hubbard model

ALEXANDER WIETEK (Presenter), MILES STOUDENMIRE, Center for Computational Quantum Physics, Flatiron Institute — The phase diagram of the two-dimensional Hubbard model at finite temperature poses one of the most interesting conundrums in contemporary condensed matter physics. Tensor network techniques, such as matrix-product based approaches as well as 2D tensor networks (PEPS), yield state-of-the-art unbiased simulations of the 2D Hubbard model at zero temperature and are capable of giving unbiased results at finite temperature as well. A promising approach for applying tensor networks to study finite-temperature quantum systems is the minimally entangled typical thermal state (METTS) algorithm, which is a Monte Carlo technique that samples from a family of entangled wavefunctions, and which offers favorable scaling and parallelism. We demonstrate how the METTS algorithm in combination with modern time-evolution algorithms for matrix-product states, like the time-dependent variational principle (TDVP) method, allows simulating the Hubbard model at finite temperature for cylinder geometries approaching the two-dimensional limit.

Comparison of systematically improvable DMC and AFQMC for condensed matter

ANOUAR BENALI (Presenter), Argonne Natl Lab, FIONN MALONE, MIGUEL A MORALES, Lawrence Livermore National Laboratory, LUKE SHULENBURGER, Sandia National Laboratories — Diffusion Monte Carlo (DMC) and Auxiliary Field Quantum Monte Carlo (AFQMC) can both have their approximations systematically improved by applying successively more accurate trial wavefunctions. In this work we assess the cost and feasibility of determining exact total energies for solid state Hamiltonians by studying primitive cells of four representative materials, Al, LiF, C and TiO2. Specifically, we utilize multideterminant trial wavefunctions generated via selective CI techniques with various sizes of single particle basis. Attention is paid to the rate at which the error decreases as the trial wavefunction includes more determinants and also to the cost as the basis increases in size. In this way, we are able to compare both DMC and AFQMC on equal terms at identical levels of approximation.

*Supported by US DOE BES, Mat. Sci. and Engn. Div., Comput. Mat. Sci. Prog. and Center for Predictive Simulation of Functional Materials. Calculations used resources of the Argonne Leadership Computing Facility, which is a DOE Office of Science User Facility supported under Contract DE-AC02-06CH11357 and the Livermore Computing Facilities. SNL is managed and operated by NTESS under DOE NNSA contract DE-NA0003525
Quantum Monte Carlo with orbital optimization applied on solids

YE LUO (Presenter), Argonne Natl Lab — The accuracy and efficiency of quantum Monte Carlo (QMC) methods can be improved directly by improving many body wavefunction. Full wavefunction optimization introduced a decade ago enabled solving scientific challenges beyond chemical accuracy. Recently algorithmic development pushed the computational efficiency of wavefunction derivatives and thus paved the way for simulation with large electron counts although demonstrations are mostly limited to molecular systems. When applying QMC in solids, using fixed orbitals calculated by density functional theory (DFT) together with variationally optimized Jastrow factors is still the common practice. Recent study on bandgaps shows qualitative improvement by simply adding limited multi determinant expansion. This hints the necessity of improving single particle orbitals restricted by DFT. Thus, we enable orbital optimization schemes like mixing occupied and unoccupied orbitals or directly optimizing orbital shapes and study their strength and weakness on solid state systems.

*This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, as part of the Computational Materials Sciences Program and Center for Predictive Simulation of Functional Materials.

Auxiliary-Field Quantum Monte Carlo Applied to Correlated Materials

FIONN MALONE (Presenter), Lawrence Livermore Natl Lab, JOONHO LEE, Department of Chemistry, Columbia University, SHUAI ZHANG, Laboratory for Laser Energetics, University of Rochester, MIGUEL A MORALES, Lawrence Livermore Natl Lab — In this talk we investigate the application of auxiliary-field quantum Monte Carlo (AFQMC) to correlated materials. Focusing on elemental transition metals and their oxides we systematically investigate the effect of trial wavefunction and basis set quality on the energetics and static properties computed from AFQMC. We show how recent algorithmic developments allow us to reliably reach the thermodynamic limit and compare directly to experiment.

*The work of FDM, SZ and MAM was performed under the auspices of the U.S. Department of Energy (DOE) by LLNL under Contract No. DE-AC52-07NA27344. FDM, SZ and MAM acknowledge funding support from the U.S. DOE, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, as part of the Computational Materials Sciences Program and Center for Predictive Simulation of Functional Materials (CPSFM).
10:48AM F40.00013: Magnetic and charge orders in the ground state of the 2D repulsive Hubbard model

HAO XU (Presenter), William & Mary College, MINGPU QIN, School of Physics and Astronomy, Shanghai jiao tong University, HAO SHI, YUAN-YAO HE, SHIWEI ZHANG, Center for Computational Quantum Physics, Simons foundation — Using the auxiliary field quantum Monte-Carlo (AFQMC) method combined with a self-consistent constraint [1], we systematically study the ground state of the two-dimensional repulsive Hubbard model as a function of doping and interaction strengths. We focus on the spin and charge correlations, applying pinning fields to break translational symmetry and computing the spin and charge densities to probe the emergence of long-range order and collective modes. A phase diagram of spin-density and charge-density waves (including stripes) is obtained.

*The work is supported by Simons Foundation.

Session F41 GMAG DMP: Skyrmion Crystals 707 - Lingfei Wang, Seoul National University

8:00AM F41.00001: Skyrmion crystal from RKKY interaction mediated by 2DEG ZHENTAO WANG (Presenter), University of Tennessee, Knoxville, YING SU, SHIZENG LIN, Theoretical Division, T-4 and CNLS, Los Alamos National Laboratory, CRISTIAN BATISTA, University of Tennessee, Knoxville — Skyrmion crystals have been found in centro-symmetric itinerant magnets, where the long-range Ruderman-Kittel-Kasuya-Yoshida (RKKY) effective coupling is believed to be the dominant interaction between the local moments. In this work we show that the RKKY interaction mediated by a dilute ($k_F \ll 1$) 2D electron gas (2DEG) on a C$_6$ invariant lattice stabilizes a magnetic skyrmion crystal in the presence of magnetic field and easy-axis anisotropy. A remarkable aspect of this mechanism is that the ordering wave vectors of the resulting skyrmion crystal are dictated by the Fermi wave vector: $|Q_\nu| = 2k_F$ ($\nu = 1, 2, 3$). Consequently, the topological contribution to the Hall conductivity of the 2DEG becomes very large within the weak-coupling regime: the quantized value $e^2/h$ is reached when $J$ becomes comparable to the Fermi energy $E_F$. 
Magnetic hedgehog lattices in noncentrosymmetric metals* SHUN OKUMURA (Presenter), Department of Applied Physics, University of Tokyo, SATORU HAYAMI, Department of Physics, Hokkaido University, YASUYUKI KATO, YUKITOSHI MOTOME, Department of Applied Physics, University of Tokyo — Recently, three-dimensional topological spin textures called the magnetic hedgehog lattices (HLs) were discovered in the B20-type compounds MnSi_{1-x}Ge_x [1]. The HLs have periodic arrays of magnetic monopoles and anti-monopoles, which induce interesting transport phenomena, such as the topological Hall effect and the topological thermoelectric transport. However, their stabilization mechanism has not been fully understood thus far. Here we investigate the ground state of an effective spin model with long-range interactions arising from the itinerant nature of electrons by variational calculations and simulated annealing. We find that the HLs are stabilized even at zero field by the synergetic effect of symmetric and antisymmetric interactions from the spin-charge and spin-orbit couplings, respectively. We also clarify the full phase diagram in the magnetic field, which includes multiple phase transitions with changes in the number of monopoles and anti-monopoles [2].

Ordering in magnetic skyrmion lattices* JAMES STIDHAM (Presenter), MICHEL PLEIMLING, Virginia Tech — Ordering in magnetic skyrmion lattices is an active area of research for skyrmion systems. In this talk, we present recent results obtained using Langevin molecular dynamic simulations, based on a previously derived particle model of skyrmions. Using a Voronoi cell algorithm, we examine the effect of the Magnus force present in skyrmion systems and how it affects ordering when noise is both present and absent in the system. We observe power-law behavior during late time ordering in these skyrmion systems. We also find power-law behavior when looking at the difference in time of consecutive events as the system orders.

*This research was supported by the US Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Grant No. DE-SC0002308.
Formation of square skyrmion lattice in a centrosymmetric magnet without geometrical frustration

Khanh Nguyen (Presenter), Taro Nakajima, Xiuwen Yu, Shang Gao, Max Hirschberger, Riken Center for Emergent Matter Science, Yuichi Yamasaki, Nims, Hajime Sagayama, Hiromi Nakao, KEK, Licong Peng, Kiyomi Nakajima, Riken Center for Emergent Matter Science, Kiyou Shibata, Rina Takagi, The University of Tokyo, Taka-Hisa Arima, Riken Center for Emergent Matter Science, Yoshinori Tokura, Shinichiro Seki, The University of Tokyo — Magnetic skyrmion, a topologically stable swirling spin texture, has attracted attention as a particle-like object potentially suitable for high-density information bit. The previous observation of skyrmions has mostly focused on noncentrosymmetric systems with Dzyaloshinskii-Moriya interaction, while the further search of novel mechanisms to realize smaller skyrmion is highly demanded. Here, we report the observation of square skyrmion lattice for a centrosymmetric non-frustrated tetragonal magnet GdRu$_2$Si$_2$ by performing resonant x-ray scattering and Lorentz TEM experiments. The possible origin of observed skyrmion formation has been discussed in terms of four-spin interaction mediated by itinerant electrons. The present results demonstrate that skyrmions can be stabilized even without geometrical frustration and inversion symmetry breaking, and suggest that rare-earth intermetallics with highly-symmetric crystal lattice may be ubiquitously platforms to explore nanometric skyrmions of exotic origins.

**8:48AM F41.00005: Dramatic enhancement of the skyrmion phase-space of Cu$_2$OSeO$_3$ driven by high pressure**

LIANGZI DENG (Presenter), HUNG-CHENG WU, ALEXANDER LITVINCHUK, Texas Center for Superconductivity and Physics Department at the Univ of Houston, NOAH YUAN, Massachusetts Institute of Technology, JEY-JAU LEE, National Synchrotron Radiation Research Center, Taiwan, RABIN DAHAL, Texas Center for Superconductivity and Physics Department at the Univ of Houston, LIANG FU, Massachusetts Institute of Technology, HELMUTH BERGER, Institute of Physics of Complex Matter, Switzerland, HUNG-DUEN YANG, Department of Physics, National Sun Yat-sen University, Taiwan, ZHENG WU, MELISSA GOOCH, PAUL C. W. CHU, Texas Center for Superconductivity and Physics Department at the Univ of Houston — Generally, the skyrmion phase in a bulk helimagnet occurs only over a very restricted magnetic-field – temperature phase space and often at low temperatures. We have expanded and enhanced the skyrmion phase region from the small range of (55-58.5 K) to (5-300 K) in single crystal Cu$_2$OSeO$_3$ by pressures up to 42.1 GPa through a series of phase transitions from the cubic $P2_13$, through orthorhombic $P2_12_12_1$ and monoclinic $P2_1$, and finally to the triclinic $P1$ phase, using our newly developed ultrasensitive high pressure magnetization technique. The results are in agreement with our Ginzburg - Landau free energy analyses that pressure tends to stabilize the skyrmion states and at higher temperatures. These observations also show that the skyrmion state can be achieved at higher temperatures in various crystal symmetries, suggesting the insensitivity of skyrmions to the underlying crystal lattices and thus the possibility of finding more ubiquitous presence of skyrmions in helimagnets.

9:00AM F41.00006: Detection of magnetic skyrmion tubes in cubic B20 FeGe nanostructures

NITISH MATHUR (Presenter), MATTHEW JOHN STOLT, Department of Chemistry, 1101 University Avenue, Madison, WI-53706, University of Wisconsin Madison, FEHMI YASIN, RIKEN CEMS, Wako Japan - 3510198, PHILIPP RYBAKOV, Royal Institute of Technology (KTH), Stockholm, NIKOLAI S. KISELEV, Forschungszentrum Jülich, Germany, XIUZHEN YU, RIKEN CEMS, Wako Japan - 3510198, SONG JIN, Department of Chemistry, 1101 University Avenue, Madison, WI-53706, University of Wisconsin Madison —

In chiral helimagnets with the non-centrosymmetric cubic B20 crystal structure, such as FeGe, host magnetic Bloch-type skyrmions due to the Dzyaloshinskii-Moriya interaction (DMI). Although magnetic skyrmions are depicted as two-dimensional spin textures in bulk crystals, in reality, they possess a three-dimensional structure of skyrmions that looks like elongated tubes extending throughout the thickness of the sample. We have synthesized single-crystal FeGe nanowires (NWs) and Fe_{1-x}Co_xGe (x<0.1) nanoplates (NPLs) via chemical vapor deposition (CVD) to explore these magnetic skyrmion tubes (SkT) in geometrically confined nanostructures. Lorentz transmission electron microscopy imaging as well as magnetotransport measurements confirmed that skyrmions are stabilized in a wider magnetic field (B_{ext}) and temperature region in these nanostructures in comparison to the bulk materials. Furthermore, magnetoresistance measurements on FeGe nanostructures have shown some unusual features when B_{ext} is parallel to the current direction. In conjunction with magnetic contrast imaging techniques and micromagnetic simulations, we have further explored the spin modulation of SkT with the variation of in-plane applied magnetic field in FeGe nanostructures.
Spectroscopic-imaging STM measurement of magnetic skyrmions in a centrosymmetric crystal

YUUKI YASUI (Presenter), CHRISTOPHER BUTLER, KHANH NGUYEN, Center for Emergent Matter Science, RIKEN, TAKUYA NOMOTO, Department of Applied Physics, The University of Tokyo, SATORU HAYAMI, Department of Physics, Hokkaido University, TETSUO HANAGURI, Center for Emergent Matter Science, RIKEN, YUKITOSHI MOTOME, RYOTARO ARITA, Department of Applied Physics, The University of Tokyo, TAKA-HISA ARIMA, Department of Advanced Material Science, The University of Tokyo, YOSHINORI TOKURA, SHINICHIRO SEKI, Department of Applied Physics, The University of Tokyo — The magnetic skyrmion, vortex-like magnetic swirling structure, has attracted attention as a topological quasi-particle. The Dzyaloshinskii-Moriya interaction originating from broken inversion symmetry in the crystal structure is considered to be the key to stabilize the skyrmion. However, a mechanism to stabilize magnetic skyrmions even in centrosymmetric crystals has been proposed [1, 2]. For such centrosymmetric systems, experiments to show how the itinerant electrons interact with the magnetic structure are highly desired for further understanding.

We performed spectroscopic-imaging scanning tunneling microscopy (SI-STM) measurements for a centrosymmetric crystal GdRu$_2$Si$_2$, which is expected to host magnetic skyrmions. As a result, we found that the density of states near the Fermi energy (0.1 eV) varies in different magnetic phases including the skyrmion phase. Besides, we also observed periodic modulation in the electronic states with the same period as the magnetic skyrmion.

In the presentation, we will discuss a possible skyrmion formation mediated by itinerant electrons.

Helical and skyrmion phases in amorphous Fe-Ge thick films

XIAOQIAN CHEN (Presenter), ROBERT STREUBEL, Lawrence Berkeley National Laboratory, DINAH SIMONE BOUMA, University of California Berkeley, ROLAND KOCH, STEPHEN DOUGLAS KEVAN, Lawrence Berkeley National Laboratory, FRANCES HELLMAN, University of California Berkeley, PETER FISCHER, SUJOY ROY, Lawrence Berkeley National Laboratory — Magnetic skyrmions are topologically protected solitons with the potential to revolutionize future spintronics and computing due to its low energy cost of manipulation. Skyrmion phase, now found in various single crystals including ferrimagnet FeGe, has recently predicted to also manifest in vector spin frustrated amorphous films. We studied amorphous Fe-Ge films using coherent resonant soft x-ray scattering. We observed magnetic Bragg peaks associated with the helical and skyrmion periodicity and mapped out their field-temperature phase diagram. We also observed spontaneous dynamics for a large range of temperatures. We calculate the respective one-time correlation functions of this fluctuation, whose characteristic curvatures indicate the distinct dynamical behavior of the helical and skyrmion textures.

Observation of Robust Néel Skyrmions in Metallic PtMnGa

SRIVASTAVA (Presenter), Nano-Systems from ions, spins and electrons, Max Planck Institute of Microstructure Physics, PARUL DEVI, Solid State Chemistry, Max Planck Institute for Chemical Physics of Solids, ANKIT SHARMA, TIANGPING MA, HAKAN DENIZ, HOLGER MEYERHEIM, Nano-Systems from ions, spins and electrons, Max Planck Institute of Microstructure Physics, CLAUDIA FELSER, Solid State Chemistry, Max Planck Institute for Chemical Physics of Solids, STUART PARKIN, Nano-Systems from ions, spins and electrons, Max Planck Institute of Microstructure Physics — Bloch[1] and anti-skyrmions[2] have attracted much attention since their first observation. Bulk Néel skyrmions have been observed in two compounds, GaV4S8[3] and VOSe2O5[4], but at low temperatures only. Here we report the first observation of bulk Néel skyrmions in a non-centrosymmetric metallic compound PtMnGa by means of Lorentz Transmission Electron Microscopy (LTEM)[5]. Skyrmions in PtMnGa are found to be stable over a wide temperature range up to its Curie temperature (~220K). By contrast with skyrmions observed to date, we find that the skyrmion size in PtMnGa is strongly influenced by the thickness of the lamella in which the skyrmions are observed. Their size increases by a factor of 7 when the thickness is increased from ~90 nm to ~4 µm. Moreover, skyrmions can be stabilized at zero field after suitable field cooling processes and are highly robust against large in-plane magnetic fields (~1 T). These properties make PtMnGa and related compounds an extremely exciting system for future spintronic applications.

New low temperature phases in chiral cubic magnets

CATHERINE PAPAS (Presenter), FENGJIAO QIAN, LARS J. BANNENBERG, ANKIT LABH, Applied Sciences, Delft University of Technology, HERIBERT WILHELM, Helmholtz Institute Ulm, ROBERT CUBITT, EDDY LELIÈVRE-BERNA, Institut Laue-Langevin, Grenoble, France, GREGORY CHABOUSSANT, Laboratoire Léon Brillouin, CEA-Saclay, Gif sur Yvette, France, LISA DEBEER-SCHMITT, Oak Ridge National Laboratory, Oak Ridge, USA, MARCUS P. SCHMIDT, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, MAXIM MOSTOVOY, Zernike Institute for Advanced Materials, University of Groningen, Netherlands, ANDREY LEONOV, Chiral Research Center, Hiroshima University, Japan — Chiral and skyrmion-hosting cubic magnets have so far been described in terms of a universal magnetic phase diagram composed of helical spiral, conical spiral, and skyrmion crystal phases. A remarkable deviation from this universal behavior occurs in Cu2OSeO3 revealed by neutron scattering and magnetization measurements. Below the upper critical field at which the conical spiral state disappears, the spiral wave vector rotates away from the magnetic field direction. We discuss the physical origin of this new state and suggest that it provides the inhomogeneous magnetic environment required to stabilise new low temperature skyrmionic phases. We discuss the different stabilization and nucleation mechanisms and the thermodynamic stability of these low temperature skyrmionics phases, as they have been investigated by neutron scattering.

10:00AM F41.00011: Weak crystallization of fluctuating skyrmion textures in MnSi* JONAS KINDERVATER, IOANNIS STASINOPOULOS, ANDREAS BAUER, FRANZ XAVER HASLBECK (Presenter), FELIX RUCKER, ALFONSO CHACON, Physics Department, Technical University of Munich, Germany, SEBASTIAN MÜHLBAUER, CHRISTIAN FRANZ, Heinz Maier-Leibnitz Zentrum (MLZ), Technical University of Munich, Germany, MARKUS GARST, Institut für Theoretische Festkörperphysik, Karlsruhe Institute of Technology, Germany, DIRK GRUNDLER, Institute of Materials and Laboratory of Nanoscale Magnetic Materials and Magnonics, École Polytechnique Fédérale de Lausanne, Switzerland, CHRISTIAN PFLEIDERER, Physics Department, Technical University of Munich, Germany — We report an experimental study of the emergence of non-trivial topological winding and long-range order across the paramagnetic to skyrmion lattice (SkL) transition in the transition metal helimagnet MnSi. Combining measurements of the susceptibility with small angle neutron scattering, neutron resonance spin echo spectroscopy and all-electrical microwave spectroscopy, we find evidence of skyrmion textures in the paramagnetic state exceeding $10^3 \text{Å}$ with lifetimes above several $10^{-9} \text{s}$. Our experimental findings establish that the paramagnetic to SkL transition in MnSi is well-described by the Landau soft-mode mechanism of weak crystallization, originally proposed in the context of the liquid to crystal transition. As a key aspect of this theoretical model, the modulation-vectors of periodic small amplitude components of the magnetization form triangles that add to zero. In excellent agreement with our experimental findings, these triangles of the modulation-vectors entail the presence of the non-trivial topological winding of skyrmions already in the paramagnetic state of MnSi when approaching the SkL transition. J. Kindervater et al., Phys. Rev. X (accepted for publication)

10:12AM F41.00012: Surface Effects in the Magnetic Textures of B20 MnGe Thin Films

JACOB REPICKY (Presenter), JOSEPH P CORBETT, TAO LIU, ADAM S AHMED, Ohio State Univ - Columbus, JONATHAN GUERRERO-SANCHEZ, Physics, Universidad Nacional Autónoma de México, ROLAND KAWAKAMI, JAY A GUPTA, Ohio State Univ - Columbus — Bulk MnGe hosts a three-dimensional skyrmion state with a period of only 3 nm. Using low-temperature (5K) spin-polarized scanning tunneling microscopy, we show that this magnetic texture is modified at the surface of MnGe thin films. We observe a stripe-like phase with a 6-8 nm period and a propagation vector that is not strongly pinned to any direction, but is influenced by step edges, surface termination, and atomic lattice strain. We also report the observation of target skyrmions with triangular shape that is set by the atomic lattice vectors, and a core size of 15 nm. We observe the target state is much more sensitive to magnetic fields than the stripe phase, and that pulses with the STM tip demonstrate the texture can be ‘switched’ between states with different topological charge. By analyzing the voltage and current applied during switching events we can determine their dependence on thermal energy of tunneling electrons, injection of spin-polarized current, or electric fields. Finally, we explore the magnetic texture in different film thicknesses and compare their larger scale film morphology to distinguish between thin film effects and true surface effects.

10:24AM F41.00013: Equilibrium Skyrmions and Antiskyrmions in Strained Bulk Ferromagnets at Room Temperature

DANIIL KITCHAEV (Presenter), ANTON VAN DER VEN, University of California, Santa Barbara — Control over skyrmion formation and topology at room temperature is foundational to the realization of skyrmion-based spintronic devices. Strained bulk ferromagnets are a rich platform for achieving both goals as strain can precisely adjust the effective magnetic Hamiltonian and thereby control the stability of emergent phases. We use phenomenological and symmetry arguments to identify simple strain fields which may stabilize chiral skyrmions over wide temperature ranges for all crystallographic point groups. We then use first-principles calculations, cluster-expansions and Monte Carlo analysis to computationally demonstrate the strain-induced formation of equilibrium skyrmions and antiskyrmions at room temperature in a proof-of-concept material. Finally, we demonstrate how strain may be used to control the relative stability of skyrmions and antiskyrmions, or engineer a state where these topologies are degenerate.

*The research reported here is supported by the Materials Research Science and Engineering Center at UCSB (MRSEC NSF DMR 1720256) through IRG-1.
10:36AM F41.00014: Investigating skyrmions using muon-spin spectroscopy*  TOM LANCASTER (Presenter), Physics, Durham University, GEETHA BALAKRISHNAN, Physics, University of Warwick, STEPHEN BLUNDELL, Physics, University of Oxford, MATJAZ GOMILSEK, Jozef Stefan Institute, THOMAS HICKEN, BENJAMIN HUDDART, Physics, Durham University, ALES STEFANCIC, Paul Scherrer Institut, MURRAY N WILSON, Physics, Durham University — We present the results of muon-spin relaxation measurements on materials hosting a skyrmion lattice (SkL) phase. We argue that the muon is primarily sensitive to the dynamics of the SkL and we have used this property to probe the local magnetism of several distinct skyrmion systems. Here we discuss our recent results on the effect of disorder on the Néel-skyrmion system GaV$_4$S$_{(8-y)}$Se$_y$ [1], where we have used low-level substitution to assess the stability of the SkL. We also discuss Zn-substituted Cu$_2$OSeO$_3$, where we show that the splitting of the SkL phase that was previously reported is only observed in polycrystalline samples and reflects the occurrence of several coexisting phases with different Zn content, each distinguished by different magnetic behavior [2]. We support our results with density functional theory calculations of the muon stopping states, that allow us an additional insight into the local environment of the muon probe.

*This work is supported by EPSRC (UK) under grants EP/N024028/1 and EP/N032128/1.

10:48AM F41.00015: Imaging the internal spin structures of skyrmions by Lorentz scanning transmission electron microscopy*  ZHEN CHEN (Presenter), Cornell University, TENG XU, Department of Physics, Tsinghua University, GREGORY FUCHS, Cornell University, WANJUN JIANG, Department of Physics, Tsinghua University, DAVID MULLER, Cornell University — Magnetic skyrmions are noncollinear spin textures that have been detected and studied using many different techniques. However, a detailed characterization of the internal spin structures of skyrmions, especially for skyrmions with diameters smaller than 100 nm, is experimentally challenging. These experiments are extremely important for defining the chirality and spin topology. Recent experiments show that Lorentz scanning transmission electron microscopy with a high-dynamic-range pixel array detector - Lorentz 4D-STEM, allows direct imaging of magnetic structures at a spatial resolution down to a few nanometers. Here we first show that Lorentz 4D-STEM technique combining with ptychography can be used to detect the detailed spin structures inside skyrmions and spin singularities in skyrmion lattices. We subsequently demonstrate the direct determination of the chirality of Néel-type skyrmions from the magnetic induction field distribution in an inclined sample setup. Using both fast, wide-field Lorentz TEM and quantitative, high-resolution Lorentz STEM, we are able to perform real-space imaging of magnetic spin textures at length scales that span microns down to a few nanometers.

*Supported by DARPA TEE program (D18AC00009).

Tuesday, March 3, 2020 8:00 AM - 11:00 AM
8:00AM F42.00001: Distinct magneto-Raman signatures of spin-flip phase transitions in CrI$_3$

AMBER MCCREARY (Presenter), THUC MAI, National Institute of Standards and Technology, FRANZ UTERMOHLEN, Ohio State University, JEFFREY SIMPSON, Towson University, KEVIN GARRITY, National Institute of Standards and Technology, XIAOZHOU FENG, Penn State University, DMITRY SHCHERBAKOV, Ohio State University, YANGLIN ZHU, Penn State University, JINHU, University of Arkansas, DANIEL WEBER, Ohio State University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, JOSHUA GOLDBERGER, Ohio State University, ZHIQIANG MAO, Penn State University, CHUN NING LAU, YUANMING LU, NANDINI TRIVEDI, ROLANDO VALDES AGUILAR, Ohio State University, ANGELA HIGHT WALKER, National Institute of Standards and Technology — The discovery of 2-dimensional (2D) materials, such as CrI$_3$, that retain magnetic ordering at monolayer thickness has resulted in a surge of research in 2D magnetism from both pure and applied perspectives. Here, we report a magneto-Raman spectroscopy study on multilayered CrI$_3$, focusing on two new features in the spectra which appear at temperatures below the magnetic ordering temperature and were previously assigned to high frequency magnons. We observe a striking evolution of the Raman spectra with increasing magnetic field in which clear, sudden changes in intensities of the modes are attributed to the interlayer ordering changing from antiferromagnetic to ferromagnetic at a critical magnetic field. Our work highlights the sensitivity of the Raman modes to weak interlayer spin ordering in CrI$_3$. In addition, we theoretically examine potential origins for the new modes, which we deduce are unlikely single magnons.

8:12AM F42.00002: Probing Tunneling Magnetoresistances in Chromium Trihalide Junctions via First Principles Calculations*

JONATHAN HEATH (Presenter), MARCELO KURODA, Auburn University — The demonstration of magnetic tunnel junctions in heterostructures formed with two-dimensional materials has spawned research ventures regarding spin transport in these layered systems. Efforts that initiated with CrI$_3$ have now been expanded to other chromium trihalides such as CrBr$_3$ and CrCl$_3$. Owing to their nanometer thicknesses, the electronic and magnetic properties of chromium trihalide systems are affected by quantum confinement effects along with their environments. Here we characterize physical properties of multilayer chromium trihalide/graphene junctions using density functional theory (DFT) and Landauer's formalism for ballistic transport. We find that band alignments in few-layer chromium trihalide (CrX$_3$ with X = F, Cl, Br and I) slabs change based on the metamagnetic state of the junctions and differ from those of isolated layers. We also delve into metamagnetic dependent complex band structures as well as discuss changes in the band structures of chromium trihalide junctions beyond DFT. Our results suggest that tunneling magnetoresistance values as high as 4,000% can be attained in bilayer heterojunctions.

*We gratefully acknowledge the financial support from NSF DMR-1848344 grant.
8:24AM F42.00003: Optically probing low energy magnetic excitations in bilayer CrI$_3$
HONGCHAO XIE (Presenter), University of Michigan - Ann Arbor, ZHIPENG YE, Texas Tech University, SHANGJIE TIAN, HECHANG LEI, Renmin University of China, RUI HE, Texas Tech University, LIUYAN ZHAO, University of Michigan - Ann Arbor — Study of spin waves, collective magnetic excitations, in two-dimensional (2D) magnets emerges as one key yet new topic in the research of 2D magnetism. Among all the 2D magnets studied so far, bilayer CrI$_3$ stands out because of the realization of the layered antiferromagnetism, in which the spins order ferromagnetically within each layer and antiferromagnetically between the two layers. So far, the magnetic excitations in natural bilayer CrI$_3$ have been rarely studied, with the exception of inelastic magneto-tunneling spectroscopy results. A further question of how such magnetic excitations depends on the angular alignment between the two layers and the resulted long-range Moiré superlattice remains totally unexplored. Here, I will first present our ultra-low frequency Raman spectroscopy studies on the spin waves in natural bilayer CrI$_3$ and discuss its comparison to the inelastic magneto-tunneling spectroscopy. I will further show the magnetic field dependence of the spin waves in natural bilayer CrI$_3$. Furthermore, I will explore how these low energy spin waves depend on the twist angle between bilayer CrI$_3$.

8:36AM F42.00004: Current Control of Magnetism in Two-Dimensional Fe$_3$GeTe$_2$ [Invited]
ARNE BRATAAS (Presenter), Norwegian Univ Tech (NTNU) — The recent discovery of magnetism in two-dimensional van der Waals systems opens the door to discovering exciting physics. We investigate how a current can control the ferromagnetic properties of such materials. Using symmetry arguments, we identify a recently realized system in which the current-induced spin torque is particularly simple and powerful. In Fe$_3$GeTe$_2$, a single parameter determines the strength of the spin-orbit torque for a uniform magnetization. The spin-orbit torque acts as a contribution to the out-of-equilibrium free energy and introduces new in-plane magnetic anisotropies to the system. Therefore, we can tune the system from an easy-axis ferromagnet via an easy-plane ferromagnet to another easy-axis ferromagnet with increasing current density. This finding enables unprecedented control and provides the possibility to study the Berezinskii-Kosterlitz-Thouless phase transition in the 2D XY model and its associated critical exponents.

9:12AM F42.00005: Enhanced magnetoresistance in mixed van der Waals magnetic tunnel junctions
DAHLIA KLEIN (Presenter), DAVID MACNEILL, Massachusetts Institute of Technology MIT, MÄRTA TSCHUDIN, Universität Basel, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology MIT — Since the recent isolation of monolayer CrI$_3$, there has been a surge of interest in van der Waals heterostructures incorporating 2D magnets. Studies have demonstrated large tunneling magnetoresistances in van der Waals magnetic tunnel junctions fabricated from the insulating layered chromium trihalides (CrX$_3$) due to the spin filter effect. Here, we report electron tunneling in graphite/CrCl$_3$/CrBr$_3$/graphite van der Waals heterostructures to study the effect of the CrCl$_3$/CrBr$_3$ interface. We find that the magnetoresistance persists above the Néel temperature of the in-plane antiferromagnet CrCl$_3$ with enhanced values compared to magnetic tunnel junctions fabricated from CrCl$_3$ alone. We interpret these data as resulting from the out-of-plane ferromagnet CrBr$_3$ acting as a spin-polarizing layer.
The recent advent of atomically-thin ferromagnetic crystals has allowed experimental studies of two-dimensional (2D) magnetism that not only exhibits novel behavior due to the reduced dimensionality but also often serves as a starting point for understanding of the magnetic properties of bulk materials. However, the experimental techniques that were used to explore two-dimensional ferromagnetism could not probe the magnetic field directly. Here we show that ballistic Hall micromagnetometry provides a reliable and convenient way to measure magnetization of individual two-dimensional ferromagnets. Our devices are made by van der Waals assembly in such a way that the investigated ferromagnetic crystal is placed on top of a multiterminal Hall bar made from encapsulated graphene. We apply the micromagnetometry to study atomically-thin chromium tribromide (CrBr$_3$). The material remains ferromagnetic down to monolayer thickness and exhibits strong out-of-plane anisotropy. Magnetic response of CrBr$_3$ varies little with the number of layers and its temperature dependence cannot be described by the simple Ising model of two-dimensional ferromagnetism.

9:36AM F42.00007: The quantum non-Heisenberg nature of two-dimensional CrI$_3$ magnets

ELTON SANTOS (Presenter), DINA WAHAB, MATHIAS AUGUSTIN, Queens Univ Belfast, SAMUEL MAÑAS-VALERO, Instituto de Ciencia Molecular, Universidad de Valencia, WENJUN KUANG, Physics, University of Manchester, SARAH JENKINS, Physics, University of York, EUGENIO CORONADO, Instituto de Ciencia Molecular, Universidad de Valencia, IRINA GRIGORIEVA, IVAN JESUS VERA MARUN, Physics, University of Manchester, EFREN NAVARRO-MORATALLA, Instituto de Ciencia Molecular, Universidad de Valencia, RICHARD F. L. EVANS, Physics, University of York, KOSTYA S. NOVOSELOV, Physics, National University of Singapore — Higher-order exchange interactions and quantum effects are widely known to play an important role in describing the properties of nano magnets. Here we show that the magnetism of recently discovered 2D CrI$_3$ cannot be captured at the level of a simple Ising model as initially thought. Using a complementary suite of magneto-optical Kerr effect microscopy, magnetic force microscopy, correlated first-principles methods and Monte Carlo techniques including higher-order exchange interactions, we identify CrI$_3$ as a quantum non-Heisenberg material. We find that biquadratic exchange interactions are essential to quantitatively describe the magnetism of CrI$_3$ but requiring quantum scaling corrections to reproduce its thermal properties. The quantization of spin-wave excitations at the low temperature regime is reflected on the fluctuations of the magnetization which follow Bose-Einstein rather than the Boltzmann statistics. These fluctuations induce the formation of metastable magnetic domains stabilizing into a single macroscopic magnetization over large surface areas. Such domains have characteristics of N'eel and Bloch types with a narrow domain wall width (3-5 nm). Similar behavior is expected for the majority of 2D vdW magnets where higher-order exchange interactions are appreciable.

9:48AM F42.00008: Substrate-assisted asymmetric electronic gap in artificial magnetic honeycomb lattice*

JIASEN GUO (Presenter), YIYAO CHEN, GEORGE YUMNAM, QUINN CUNNINGHAM, DEEPAK K SINGH, Univ of Missouri - Columbia — An artificial magnetic honeycomb lattice was prepared via physical vapor deposition. Asymmetric electronic gaps with increasing breadth were observed in the differential conductivity when applying in-plane current at low temperatures ranging from 27K to 40 K. Electrical hysteresis behavior was also observed and became more profound with increasing temperature. It was seen that an in-plane magnetic field parallel or antiparallel to the applied current tends to narrow the aforementioned gaps and reduce the degree of asymmetry drastically. Resistance measurement with applied magnetic field up to 8.5 T shows a temperature-dependent transition from positive magnetoresistance to negative magnetoresistance, which we suspect, is subject to the effect of the substrate. The observed negative magnetoresistance can be explained as the giant magnetoresistance effect due to the ordering of magnetic moment on the artificial honeycomb lattice.

10:00AM F42.00009: Magneto-Raman study of the Neel-type Antiferromagnet MnPSe$_3$*

THUC MAI (Presenter), National Institute of Standards and Technology, JOSHUA ARGO, Materials Science and Engineering, The Ohio State University, AMBER MCCREARY, National Institute of Standards and Technology, ROLANDO VALDES AGUILAR, Physics, The Ohio State University, VICKY DOAN-NGUYEN, Materials Science and Engineering, The Ohio State University, ANGELA HIGHT WALKER, National Institute of Standards and Technology — The discovery of 2D magnetism in van der Waals materials such as CrI$_3$ and Cr$_2$Ge$_2$Te$_6$ demonstrated that long range magnetic ordering can survive in the monolayer limit, given that the material has sufficiently large anisotropy. MnPSe$_3$ is a layered material with Neel-type antiferromagnetic spins lying parallel to the basal plane. We perform a systematic magneto-Raman study of MnPSe$_3$. Multiple excitation laser wavelengths were used. With resonant Raman condition, we study the temperature and magnetic field dependence of the Raman spectrum of single crystal MnPSe$_3$. A drastic shift in the phonon spectrum across T$_{\text{Neel}}$ is observed. We compare the spin-phonon coupling between bulk and thin samples.

Work at OSU was supported by the Center for Emergent Materials, an NSF MRSEC under grant DMR-1420451. This was also supported in part by The Ohio State University Institute for Materials Research. X-ray diffraction was performed at the Center for Electron Microscopy and Analysis (CEMAS) at The Ohio State University.

10:12AM F42.00010: Magnetic structure determination of transition metal dichalcogenide Fe$_{1/3}$NbS$_2$*

SHAN WU (Presenter), University of California, Berkeley, ZHIJUN XU, (NCNR, National Institute of Standards and Technology), ERAN MANIV, ARANI ACHARYA, SPENCER DOYLE, CAOLAN JOHN, JAMES ANALYTIS, ROBERT J BIRGENEAU, University of California, Berkeley — In layered transition metal dichalcogenides (TMD) MA$_2$ (M = Ta, Nb, A = S, Se), the weak van der Waals bonding between adjacent layers allows easy intercalation of transition metal atoms. Intercalated magnetic ions, such as T = Fe, Co, Mn, Cr, occupy the vacant octahedral sites between the layers and form an ordered triangular superlattice. This introduces in the magnetic degree of freedom, giving rise to a class of layered magnetic materials with a rich array of magnetic phenomena. Recently, the current-induced switching and magnetic memory effects were reported in FexNbS$_2$ with x close to 1/3 that exhibits an antiferromagnetic transition at T$_N$ ~ 45 K. This provides a new avenue to realize the spintronic device. From neutron diffraction experiment, we determined a stripe-type order that develops into three magnetic domains, which is strongly coupled to three nematic domains. The magnetic order parameter can be explained with the development of canted moment, which is associated with competing exchange interactions in the frustrated lattice and the effect of Dzyaloshinskii-Moriya interaction because of the lack of the inversion symmetry.

*This work is funded by the U.S. DOE, Materials Sciences and Engineering Division under Contract No. DE-AC02-05-CH11231 within the QM Program (KC2202).
Magnetic interactions and excitations in magnetic 2D van der Waals materials* LIQIN KE (Presenter), Ames Laboratory — Magnetic 2D van der Waals (m2DvdW) materials add new functionality, leading to novel new magnetic 2D devices. Using linear-response ab initio methods, we investigate the magnetic interactions and spin excitations in various m2DvdW systems. Dynamical spin susceptibility is calculated using single-particle Hamiltonians constructed within density-functional theory (DFT) and the quasiparticle self-consistent GW (QSGW) methods. Results are compared with available Inelastic Neutron Scattering (INS) measurements. We found that the more elaborate description of electron interactions better describes the magnetic interactions within 2D van der Waals systems. For example, plain DFT overestimates the exchange couplings in CrI3, while the spin-wave spectrum calculated in QSGW is closer to experiments. The effects of Dzyaloshinskii-Moriya interaction on spin excitations are also discussed.

*This work was supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, Materials Sciences and Engineering Division, and Early Career Research Program. Ames Laboratory is operated for the U. S. Department of Energy by Iowa State University under Contract No. DE-AC02-07CH11358.

Is 2H-MoTe₂ an intrinsically magnetic semiconductor?* JONAS A. KRIEGER, ZURAB GUGUCHIA, TONI SHIROKA, THOMAS PROKSCHA, ANDREAS SUTER, VLADIMIR STROKOV, ZAHER SALMAN (Presenter), Paul Scherrer Institute — Layered transition metal dichalcogenides are currently intensively investigated due to their opto-electronic, superconducting and topological properties as well as their potential usage as mono-layer building blocks. However, despite their layered nature they often exhibit three dimensional (3D) properties in the bulk. A recently detected long-range magnetic order in semiconducting 2H-MoTe₂ was attributed to defects [1]. Here we present results of complementary spectroscopic techniques to elucidate the nature and origin of the reported magnetic order. We find that the magnetism is intrinsic with a layered-antiferromagnetic ground state. Our results also show that this magnetism remains unchanged near the surface, opening new possibilities for applications of 2H-MoTe₂ in interface engineering.

Patterning-induced ferromagnetism of Fe₃GeTe₂ van der Waals materials beyond room temperature

MENGMENG YANG (Presenter), QIAN LI, CHENG GONG, University of California, Berkeley, RAJESH V CHOPDEKAR, ALPHA T. N'DIAYE, JOHN TURNER, Lawrence Berkeley National Lab, GONG CHEN, University of California-Davis, ANDREAS SCHOLL, PADRAIC SHAFER, ELKE ARENHOLZ, ANDREAS SCHMID, Lawrence Berkeley National Lab, SHENG WANG, University of California, Berkeley, KAI LIU, University of California-Davis, NAN GAO, University of California, Berkeley, ALEMAYEHU S ADMASU, SANG-WOOK CHEONG, Rutgers University, New Brunswick, CHANYONG HWANG, Korea Research Institute of Standards and Science, JIA LI, Peking University, FENG WANG, XIANG ZHANG, ZI Q. QIU, University of California, Berkeley — Magnetic van der Waals (vdW) materials have emerged as promising candidates for spintronics applications especially after the recent discovery of intrinsic ferromagnetism in monolayer vdW materials. There has been a critical need for tunable ferromagnetic vdW materials beyond room temperature. Here we report a real space imaging study of itinerant ferromagnet Fe₃GeTe₂ and the enhancement of its Curie temperature well above ambient temperature. We find that the magnetic long-range order in Fe₃GeTe₂ is characterized by an unconventional out-of-plane stripe domain phase. In Fe₃GeTe₂ microstructures patterned by focused ion beam, the out-of-plane stripe domain phase undergoes a surprising transition at 230 K to an in-plane vortex phase that persists beyond room temperature. The discovery of tunable ferromagnetism in Fe₃GeTe₂ materials opens up vast opportunities for utilizing vdW magnets in room temperature spintronics devices.

Session F43 DCOMP DAMOP DCMP: Precision many-body physics III: Non-perturbative QFT 702 - James LeBlanc, Memo Univ of Newfoundland - Tag(s): Focus

Particle transmutations in flat-band lattices: bosons to fermions, fermions to composite fermions [Invited] SAURABH MAITI (Presenter), Concordia Univ, TIGRAN SEDRAKYAN, Physics, University of Massachusetts, Amherst — Understanding new quantum states and exotic quasiparticles can often be facilitated by approaching the problem in a different basis. One such example, amongst many, is viewing hard core bosons as fermions coupled to a special gauge-field (called the Chern-Simons gauge field). The non-Maxwellian nature of this gauge field introduces new challenges in treating such a problem. However, progress has been made by treating the problem via various mean-field schemes. In this talk, we will draw our attention to the consequences of one particular scheme that is designed to be applicable for various interesting 2D lattices. We will see how this scheme leads to a particular intra-unit cell flux distribution that provides a natural description of the system in the parameter space where a chiral spin-liquid is stabilized for bosons residing in either a Honeycomb lattice or a Kagome lattice. We will view these results in light of other numerical works in the literature. Interestingly, we will also see that when the same scheme is applied to fermions in a lattice, subject to an external magnetic field, we can make interesting predictions related to the composite fermion state: in particular the theory suggests that Graphene with next nearest neighbor hopping at the half-filling condition should be a doped Haldane-Chern insulator of composite fermions.
8:36AM F43.00002: Coherent states, Gram matrix, and Hofstadter butterfly with flat band
YOUJIANG XU (Presenter), HAN PU, Rice Univ — Through a concrete example, we illustrate that the correspondence between Gram matrices and Hamiltonians may open up grand opportunities to discover novel systems. We find that the Gram matrices of certain subsets of coherent states, whose associating eigenvalues form a lattice on the complex plane, can be interpreted as Hamiltonians which govern the dynamics of a particle hopping around the lattice under a gauge field. The completeness of the subsets of coherent states guarantees massive degeneracy of the ground states of the Hamiltonians, which is independent from the shape of the lattice, while different types of lattice result in different Hofstadter-butterfly-like patterns in the excitation spectrum. The models also feature ground state wave functions in universal form whose dynamics is special. Numerical evidence suggests that it is highly possible to study the models experimentally.

8:48AM F43.00003: Chern-Simons fermionization approach to the chiral spin liquid on a frustrated square lattice with moat band*
RUI WANG (Presenter), Nanjing Univ, Z. Y. XIE, Renmin Unvi, HAIYUAN ZOU, Shanghai Jiao Tong Univ, WEI SU, Nanjing Univ, TIGRAN SEDRAKYAN, Umass, Amherst, BAIGENG WANG, D. Y. XING, Nanjing Univ — We utilize the Chern-Simons (CS) fermionization to study quantum spin XY models on a square lattice in the regime where the lattice dispersion exhibits a moat-like structure. We analytically derive the low-energy effective field theory, and predict a possible non-uniform chiral spin-liquid (CSL) ground state. Using high-precision numerical calculations such as the tensor network renormalization group based on projected entangled paired state (PEPS), we obtain numerical evidences that further suggest the stabilization of the non-uniform CSL. Finally, we show that the CS fermionization approach is also able to describe the magnetically ordered phases, which are captured by a CS superconducting state with condensation of Cooper pairs of CS fermions. By comparing the Goldstone mode of the magnetically ordered phase and that of the CS superconductor, we found high-precision agreements that suggest the equivalence of the two states in terms of the low-energy excitations.

9:00AM F43.00004: Viscous Topological Electromagnetic Phases of Matter* ZUBIN JACOB (Presenter), Purdue Univ — We present the fundamental model of a topological electromagnetic phase of matter: viscous Maxwell-Chern-Simons theory. We solve both continuum and lattice regularized systems to demonstrate that this is the minimal (exactly solvable) gauge theory with a nontrivial photonic Chern number for electromagnetic waves coupled to matter $C \neq 0$. Physically, our predicted electromagnetic phases are connected to a dynamical photonic mass in the integer quantum Hall fluid. This arises from viscous (nonlocal) Hall conductivity and we identify the nonlocal Chern-Simons coupling with the Hall viscosity. The electromagnetic phase is topologically nontrivial $C \neq 0$ leading to unidirectional transverse electromagnetic edge waves when the Hall viscosity inhibits the total bulk Hall response. Our work bridges the gap between electromagnetic and condensed matter topological physics while also demonstrating the central role of spin-1 quantization in nontrivial photonic phases.

9:12AM F43.00005: Imaging impurities at quantum Hall edges in graphene: Dissipation rings induced by forward scattering GU ZHANG (Presenter), IGOR GORYNI, ALEXANDER MIRLIN, Karlsruhe Institute of Technology — Motivated by the recent experiment by Marguerite et al. on imaging in graphene samples, we investigate theoretically the dissipation induced by resonant impurities in the quantum Hall regime. Briefly, the impurity induced forward scattering of quantum Hall particles leads to an enhanced phonon emission, which reaches its maximum when the impurity state is fine tuned to its resonance by an applied tip voltage. Our analysis of the effect of a tip potential on the dissipation thus reveals peculiar thermal rings near the impurity, in consistency with experimental observations. This thermal ring behavior, while appearing similar as that in two dimensional materials, turns out to be physically novel and contains features that are unique in quantum Hall systems.

9:24AM F43.00006: Repulsive Casimir force in time-reversal symmetry broken media* ZHOU LI (Presenter), ZUBIN JACOB, Purdue Univ — In quantum field theory, a vacuum is not empty but full of fluctuating electromagnetic waves. If two dielectric mirrors (silicon plates) are placed facing each other in vacuum, it is well known that there exists an attractive Casimir force between them. When one of the silicon plates is replaced by a medium with time-reversal symmetry breaking (usually achieved by an external magnetic field), we show that the Casimir force can become repulsive. This opens the possibility of controlling the quantum vacuum with non-reciprocal media.

*DARPA NLM
9:36AM F43.00007: Supersymmetry approach to interacting disordered systems: the SYK model
TIGRAN SEDRAKYAN (Presenter), Univ of Mass - Amherst, KONSTANTIN EFETOV, Theoretical Physics, Ruhr-University, Bochum, Germany — In this talk, we propose a new, supersymmetric sigma-model representation for interacting disordered fermion systems. To derive it, we decouple the interaction Hamiltonian using the conventional Hubbard-Stratonovich approach. Then we notice that the Hubbard-Stratonovich field can, in some situations, be gauged out from the denominator. This enables one to supersymmetrize the interacting theory. The new formalism is tested by calculating the fermion Green's function in the SYK model at large times and is argued to be effective for other interacting models with the disorder.

9:48AM F43.00008: Spin and charge correlations across the metal-to-insulator crossover in the half-filled 2d Hubbard model*
AARAM J. KIM, FEDOR SIMKOVIC, EVGENY KOZIK (Presenter), King's College London — The 2d Hubbard model with nearest-neighbour hopping on the square lattice and an average of one electron per site is known to undergo an extended crossover from metallic to insulating behavior driven by proliferating antiferromagnetic correlations. We study signatures of this crossover in spin and charge correlation functions and present results obtained with controlled accuracy using diagrammatic Monte Carlo in the range of parameters amenable to experimental verification with ultracold atoms in optical lattices. The qualitative changes in charge and spin correlations associated with the crossover are observed at well-separated temperature scales, which encase the intermediary regime of non-Fermi-liquid character, where local magnetic moments are formed and non-local fluctuations in both channels are essential.

10:00AM F43.00009: Equation of state and entropy of the doped 2d Hubbard Model*
CONNOR LENIHAN (Presenter), AARAM J. KIM, EVGENY KOZIK, FEDOR SIMKOVIC, Kings Coll — We study thermodynamic properties of the doped Hubbard model with nearest-neighbour hopping on the square lattice by Diagrammatic Monte Carlo and obtain results with controlled error bars in the thermodynamic limit. The behaviour of entropy reveals signatures of the insulating regime developing near half-filling at larger interactions: a maximum in the entropy as a function of density appears as the coupling strength is increased, along with an inflection point near half-filling evidencing a metal to insulator crossover. Cold atom simulations of the Hubbard model which prepare the sample adiabatically will find our data useful for thermometry.

Simons Foundation: Simons Collaboration on the Many-Electron Problem
10:12AM F43.00010: Pseudogap effects in the unitary Fermi gas and in strongly interacting 2D Fermi gases*  SCOTT JENSEN (Presenter), YORAM ALHASSID, Yale University, CHRISTOPHER GILBRETH, Central Washington University — Understanding of the unitary Fermi gas of infinite scattering length presents a major challenge owing to the presence of strong correlations. In particular, the existence and extent of a pseudogap regime, in which pairing correlations persist above the superfluid critical temperature, has been extensively debated in the literature. We address the pseudogap question using auxiliary-field quantum Monte Carlo methods on the lattice, optimized to enable large lattice calculations of thermodynamic observables. In particular, we calculate a model-independent energy-staggering pairing gap, which avoids an ill-posed numerical analytic continuation. We extrapolate to the continuum limit, thereby removing finite effective range effects. We use similar methods to study pseudogap effects in interacting 2D Fermi gases along the Bardeen-Cooper-Schrieffer (BCS) to Bose-Einstein condensation (BEC) crossover. Our results provide a benchmark for experiments and other strong coupling methods.

10:24AM F43.00011: Implicit renormalization approach to the problem of Cooper instability*  ANDREY CHUBUKOV, Physics, University of Minnesota, NIKOLAI PROKOF'EV (Presenter), BORIS SVISTUNOV, Univ of Mass - Amherst — In the vast majority of cases, superconducting transition takes place at exponentially low temperature $T_c$ out of the Fermi liquid regime. We discuss the problem of determining $T_c$ from known system properties at temperatures $T \gg T_c$, and stress that this cannot be done reliably by following the standard protocol of solving for the largest eigenvalue of the original gap-function equation. However, within the implicit renormalization approach, the gap-function equation can be used to formulate an alternative eigenvalue problem, solving which leads to an accurate prediction for both $T_c$ and the gap function immediately below $T_c$. With the diagrammatic Monte Carlo techniques, this eigenvalue problem can be solved without invoking the matrix inversion or even explicitly calculating the four-point vertex function. [Phys. Rev. B 100, 064513 (2019)]

10:36AM F43.00012: Photoinduced superconducting-like properties: \( \eta \)-pairing and charge stiffness in optically driven Mott-Hubbard systems*  TATSUYA KANEKO (Presenter), Department of Physics, Columbia University, SEIJI YUNOKI, RIKEN, ANDREW MILLIS, Department of Physics, Columbia University, Center for Computational Quantum Physics, Flatiron Institute — We theoretically investigate the electron-electron (superconducting) pairing correlations and charge stiffness in the one-dimensional Hubbard model subjected to a pump electric field. By employing unbiased numerical methods, we show that irradiation of the Mott insulating state of the Hubbard model induces strong pair density-wave-like correlations. The pair density-wave correlations induced here are due to \( \eta \)-pairing states, which are preferentially generated by photoexcitation and possess staggered off-diagonal long-range correlations in the excited states of the Hubbard model. We show that the optically induced \( \eta \)-pairing states give rise to the nonzero charge stiffness, in contrast to the Mott insulating state, where the charge stiffness vanishes. We also discuss the system size dependence associated with the \( \eta \)-pairing state and show that the pairing correlations decay very slowly with system size.

*This work is supported by Grants-in-Aid for Scientific Research from JSPS (Projects No. JP18K13509 and No. JP18H01183) and the Basic Energy Sciences program of the US Department of Energy under grant DE-SC0018218. T.K. was supported by the JSPS Overseas Research Fellowship.

10:48AM F43.00013: Pairing tendencies in two-orbital Hubbard models with reduced sign problem  EDWIN HUANG (Presenter), University of Illinois at Urbana-Champaign, ABOLHASSAN VAEZI, Stanford University and Sharif University of Technology — How unconventional superconductivity arises from strong repulsive interactions is a central question in the study of high-temperature superconductivity. Here we study two-orbital Hubbard models with orbital-dependent interaction strength by large-scale Determinantal Quantum Monte Carlo (DQMC) simulations. When one orbital is strongly interacting and the other is weakly or non-interacting, the fermion sign problem is significantly reduced. Temperatures more than two orders of magnitude below the Fermi energy are accessible by DQMC. We present results for the superfluid stiffness and pairfield susceptibilities of such models and comment on their relevance to unconventional superconductors, including the recently discovered superconducting nickelates.

Session F44 DCOMP: Van Der Waals Interactions in Molecules, Materials, and Complex Environments I  704 - Noa Marom, Carnegie Mellon Univ - Tag(s): Focus
8:00AM F44.00001: Quantum-mechanical van der Waals Interactions from Atoms to Asteroids [invited] ALEXANDRE TKATCHENKO (Presenter), University of Luxembourg — Noncovalent van der Waals (vdW) interactions arise from quantum-mechanical electronic and atomic fluctuations and they are ubiquitous in essentially all molecules and materials [RMP 88, 045003; Chem. Rev. 117, 4714; Science 351, 1171]. Intergrain vdW interactions have even been hypothesized to explain cohesion in kilometer-sized rubble pile asteroids in space [Nature 512, 174]. I will review the substantial progress in our understanding of everpresent quantum vdW forces at the atomic, nano, and mesoscopic scales achieved during the last two decades. Then I will turn to big gaps in our knowledge where intensive research is required, including (i) the unification of vdW methods with semilocal density functionals, (ii) the scaling of vdW forces with topology, dimensionality, size, and electronic properties of materials, (iii) the interplay between atomic vibrations and electronic fluctuations in the vdW forces, (iv) the delicate transition between vdW and Casimir physics in complex systems.

8:36AM F44.00002: Dispersion-corrected MP2 for improved descriptions of inter- and intramolecular interactions in organic molecular crystals* GREGORY BERAN (Presenter), University of California, Riverside — Reliably modeling polymorphic molecular crystals requires a careful balance between intra- and intermolecular interactions. Density-functional theory models have made tremendous progress in modeling such interactions, but a number of failures for conformational polymorphs and other systems can be found in the literature. A dispersion-corrected MP2 model, MP2D, will be presented which provides more accurate descriptions of non-covalent interactions in these challenging polymorphic crystals. The MP2D dispersion correction is expressed in terms of atom-centered dispersion coefficients which are computed via Grimme's D3 scheme. This approach has the benefits that the dispersion correction can be computed for any organic system with negligible computational cost, it can be applied to both intra- and intermolecular interactions, and analytical gradients can be implemented trivially. The performance of MP2D for both benchmark data sets and in challenging polymorphic molecular crystals will be presented.

*Funding for this research from the National Science Foundation (CHE-1665212) and XSEDE supercomputer time (TG-CHE110064) are gratefully acknowledged.
8:48AM F44.00003: Van der Waals Attraction and Pauli Repulsion: Learning New Tricks from an Old Dog
ORNELLA VACCARELLI (Presenter), DMITRY FEDOROV, ALEXANDRE TKATCHENKO, University of Luxembourg Limpertsberg — The structure and stability of molecular systems bonded by van der Waals (vdW) interactions are governed by the interplay between dispersion attraction and Pauli repulsion [Hermann et al., Chem. Rev. 117, 4714 (2017)]. Arising due to different physical origins, these forces do not seem to have a simple connection. Here, we present a coarse-grained approach for evaluating the exchange energy based on the multipole expansion of the Coulomb interaction. This allows us to reveal an unexpected compensation between attractive dispersion and repulsive exchange forces for closed-shell dimers at equilibrium distance, valid for each term of the multipole expansion. This effect explains the surprisingly simple relationship between the vdW radius and atomic polarizabilities discovered recently [Fedorov et al., PRL 121, 183401 (2018)]. The obtained recipe to build coarse-grained models for the exchange-repulsive forces in vdW-bonded systems could be used to develop next-generation quantum force fields. Therefore, our findings hint on a hidden symmetry between exchange and correlation interactions and suggest a surprising connection between electronic and geometric properties of atoms.

9:00AM F44.00004: Characterization of van der Waals Interactions with Energy Decomposition Analysis*
COLIN EGAN (Presenter), FRANCESCO PAESANI, CHINGLIN CHAN, JOSHUA FIGUEROA, Chemistry, UC San Diego — Van der Waals (vdW) interactions are ubiquitous in nature, and represent important contributions to the structure, stability, and function of many chemical systems. The absolutely localized molecular orbital energy decomposition analysis method (ALMO-EDA) allows for the characterization and quantification of intermolecular interactions such as London dispersion, the predominant attractive vdW component which is due to correlated fluctuations of the electron densities between molecules, and Pauli repulsion, the predominant repulsive vdW component which is a consequence of the antisymmetry of fermionic wave functions. Here we discuss our work studying vdW interactions calculated with ALMO-EDA in small and large molecular systems, and our findings regarding the role of nonlocal terms in approximate exchange-correlation density functionals in predicting vdW interaction energies, as well as many-body cooperativity in vdW interactions.

*This work was supported by NSF grant CHE-1453204.
9:12AM F44.00005: Introducing vdW-DF3 — an accurate van der Waals Density Functional*
DEBAJIT CHAKRABORTY (Presenter), Department of Physics, Wake Forest Univ, KRISTIAN BERLAND, Centre for Material Sciences and Nanotechnology, University of Oslo, TIMO THONHAUSER, Department of Physics, Wake Forest Univ — Recently, we identified the shape of the switching function in the original van der Waals density functional vdW-DF as the key to control the relative contributions of dispersion interactions at different separations (PRB 99, 195418, 2019). Building on this development, we introduce a reformulation that results in significantly higher accuracy for several different classes of systems, in particular for separations beyond the binding distance. This is achieved through tuning the switching function (and thus the non-local correlation) as well as the (semi)local exchange to a set of molecular dimers. Our new formulation provides better binding energies at the equilibrium distance and binding curves of molecular dimers, more accurate interlayer binding energies and lattice constants for layered systems, and improved binding energies for adsorption systems such as small-molecule-adsorption in MOFs and benzene on coinage metals.

*This work was funded by NSF grant No. DMR-1712425 and the Norwegian Research Council, project No. 250346.

9:24AM F44.00006: Experimental determination of van der Waals forces between two-dimensional materials in air and water [Invited]  
PAVLO GORDIICHUK (Presenter), Department of Chemical Engineering, Massachusetts Institute of Technology MIT — Two-dimensional (2D) materials have rather diverse properties and are therefore of high interest for applications in material science, physics, chemistry, and biology. Since many of these applications rely on interfacial stacking, a fundamental understanding of the interactions between 2D materials is of paramount importance. In this work, we describe a strategy which enables rapid and high-throughput determination of the forces between 2D materials (both in air and in liquids) using atomic force spectroscopy. While our experiments demonstrate strong adhesive forces between two graphene sheets with binding energies close to theoretical values, the scaling of the van der Waals (vdW) force with the separation distance differs quite substantially from theoretical predictions. In addition, our experiments in purified water demonstrate that the water confined between two hydrophobic surfaces leads to repulsive interactions, with increasing ionic strength reverting this behavior. These experiments challenge our current understanding of the vdW force and provide much needed experimental benchmarks for the further development of theoretical vdW methodologies.
**10:00AM F44.00007: Influence of Pore Size on the van der Waals Interaction in Two-Dimensional Molecules and Materials**

YAN YANG (Presenter), KA UN LAO, ROBERT DISTASIO, Cornell University — Despite the importance of porous two-dimensional (2D) molecules and materials in advanced technological applications, the question of how the void space in these systems affects the van der Waals (vdW) scaling landscape has been largely unanswered. In this work [1], we present a series of analytical and numerical models demonstrating that the mere presence of a pore leads to markedly different vdW scaling across non-asymptotic distances, with certain relative pore sizes yielding effective power laws ranging from simple monotonic decay to the formation of minima, extended plateaus, and even maxima. These models are in remarkable agreement with first-principles approaches for the 2D building blocks of covalent organic frameworks (COFs), and reveal that COF macrocycle dimers and periodic bilayers exhibit unique vdW scaling behavior that is quite distinct from their nonporous analogs. These findings extend across a range of distances relevant to the nanoscale, and represent an unexplored avenue towards governing the self-assembly of complex nanostructures from porous 2D molecules and materials.

*NSF MRSEC program (Grant No. DMR-1719875)*

**10:12AM F44.00008: Ultra Long-Range Interactions in the Delamination of Atomically-Thin Layers from Substrates**

PAUL HAUSEUX (Presenter), STÉPHANE BORDAS, ALEXANDRE TKATCHENKO, University of Luxembourg — Anomalous proximity effects have been experimentally observed in systems ranging from proteins, bacteria, and gecko feet suspended over semiconductor surfaces to interfaces between graphene and different substrate materials (Si, SiO2, Cu). In the latter case, long-range forces are evidenced by measurements of a non-vanishing stress that extends up to micrometer separations between graphene and the substrate. State-of-the-art models to describe adhesive properties are unable to explain these experimental observations, instead underestimating the measured distance range by 2-3 orders of magnitude. Here we develop an analytical and numerical variational approach that combines continuum mechanics and elasticity with quantum many-body treatment of van der Waals dispersion interactions between two extended objects. A full relaxation of the coupled adsorbate/substrate geometry as a function of separation leads us to conclude that wavelike atomic deformation is responsible for the observed ultra long-range stress in delamination of graphene from various substrates. Remarkably, the observed long-range proximity effect seems to be a general phenomenon for thin membranes and its correct theoretical description requires a direct coupling between quantum and continuum mechanics.
Recent atomic force microscopy experiments [ACS Nano 2014, 8, 12410–12417] conducted on graphene (G)-coated SiO$_2$ demonstrated that monolayer G can effectively screen dispersion van der Waals (vdW) interactions deriving from the underlying substrate. This G vdW opacity has far reaching implications, encompassing stabilization of multilayer heterostructures, micromechanical phenomena and heterogeneous catalysis. By quantum many-body analysis and ab-initio Density Functional Theory, here we provide theoretical rationalization of the observed G vdW screening on weakly interacting substrates: despite single atom thickness, the strong non-locality of G density response ensures large compensation between standard attractive vdW terms and many-body repulsive contributions, enabling effective vdW opacity over a broad range of distances. By virtue of combined theoretical/experimental validation, G hence emerges as a promising ultrathin shield for modulation and switching of vdW interactions and electrostatic fields at interfaces and complex nanoscale devices.

Tuesday, March 3, 2020 8:00 AM - 10:48 AM

Session F45 DCOMP DCP: Modeling the electrochemical interface and aqueous solutions I 706 - Alexandre Rocha, Universidade Estadual Paulista - Tag(s): Focus
Addressing electrified water-metal interfaces with Non-Equilibrium Green's Functions* [Invited]  
PABLO ORDEJON (Presenter), Theory and Simulation, Catalan Institute of Nanoscience and Nanotechnology — The TranSIESTA method and code [1,2] were developed within the SIESTA project [3] to study problems involving steady-state non-equilibrium problems in nanoscale costrictions, where an external electric bias is applied between the two sides of the constriction, establishing a steady electric current. Non-equilibrium Green's Functions are used there to solve the problema, as they can deal with open, non periodic systems (leads plus nanoconstriction) driven out of equilibrium (external applied bias). This machinery can be also used to study electrified solid/liquid interfaces [4], where an external bias is applied to the solid electrode. Here, one is not concerned with the quantum electronic transport, but with the effect of the external bias on the properties and the chemical reactions induced at the metal/liquid interface. I will show examples of application of this idea, as a proof of concept for future realistic, atomistic first-principles simulations of electrochemical processes.

8:36AM F45.00002: First principles simulations of electrified silicon/water interfaces

ZIFAN YE (Presenter), BOZHI TIAN, GIULIA GALLI, University of Chicago — Si-based materials have been used in a myriad of devices, including light-activated systems such as cathodes in photoelectrochemical cells and p-i-n junctions in optoelectronic biomodulators. In both cases, Si surfaces are in contact with water, and the interface is under bias (e.g. under the effect of an electric field). Here we report a study of electrified Si/water interfaces aimed at understanding charge transfer mechanisms between the solid and the liquid, and their influence in determining the performance of optoelectronic devices. In particular, we carried out ab-initio molecular dynamics simulations of the hydrogenated Si(100)/water interface using the Qbox code (http://qboxcode.org), and we investigated the effect of an applied electric field on the band offsets at the interface. We compared our results with patch clamp measurements and we further investigated the modification of the structural properties of water at the interface, induced by an applied bias.

8:48AM F45.00003: Ion Pairing in Liquid Water: An Ab Initio Study

ALEC WILLS (Presenter), MARIVI FERNANDEZ SERRA, Physics & Astronomy, Stony Brook University — Potentials of mean force are widely used to study solvation characteristics as a function of a particular reaction coordinate of interest. In particular, ion-pair association in water is of great importance to many scientific and industrial applications, but is not widely understood. Here we present a detailed study of NaCl solvation properties in the dilute limit. We examine in detail the sources of discrepancies between simulation results, with the objective to separate approximation and statistical errors from physical interpretations. It is found that the choice of water model and simulation time step has a notable effect on the solvation state stability. Moreover, solution density also has a large effect on energetically favorable configurations. We show how the underlying description of liquid water has important consequences on the inter-ionic potential of mean force, and how the solute ions affect the solution's equilibrium properties. Our results shed light into how ions in water affect its structure and correlate with low density and high density liquid fluctuations.

9:00AM F45.00004: Integrating First-Principles Simulations with Electrochemical Experiments: Towards a Realistic Description of Aqueous Interfaces  TUAN ANH PHAM (Presenter), CHENG ZHAN, BRANDON WOOD, TADASHI OGITSU, Lawrence Livermore Natl Lab — Improved understanding of electrochemical interfaces is critical for a wide variety of emerging applications, such as hydrogen production, supercapacitors and water desalination. In this talk, we will discuss how first-principles simulations can be integrated with in-situ experiments to understand physicochemical properties of several representative electrochemical systems. We will present our studies of aqueous solutions at graphitic interfaces, where we show that structure and electrical response of the interfaces is governed by a complex interplay between bias potential, intrinsic electronic properties of the electrode, and specific ion effects-including ion hydration and charge transfer. In addition, we will discuss how a combination of first-principles molecular dynamics simulations, many-body perturbation theory, and X-ray photoelectron spectroscopy can provide insights into the relationship between interfacial structure, electronic properties of semiconductors and their reactivity in aqueous solutions.

This work was performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344, and is supported by the U.S. DOE, Office of Energy Efficiency and Renewable Energy, Fuel Cell Technologies Office via HydroGEN consortium

9:12AM F45.00005: Stability and reactivity at solid/liquid interfaces studied by ab initio calculations [Invited]  MIRA TODOROVA (Presenter), SU-HYUN YOO, SUDARSAN SURENDRALAL, JOERG NEUGEBAUER, Computational Materials Design, Max-Planck-Institut fuer Eisenforschung — Processes at solid-liquid interfaces are at the heart of many present day technological challenges related to the improvement of battery materials, electro-catalysis, fuel cells, corrosion and others. Obtaining the microscopic information needed to describe and quantify the underlying fundamental mechanisms is equally challenging to experiment and theory. Density functional theory (DFT) calculations are able to resolve processes at the microscopic scale. However, the modelling of electrochemical systems is particularly challenging. The main reason is the presence of different classes of materials and phenomena such as metal electrodes, liquid water, huge electric fields within the same system.

We discuss how by using DFT calculations for polar ZnO(0001) surfaces Pourbaix diagrams can be constructed. These diagrams provide direct insight into the role the aqueous electrolyte plays in shaping surfaces and the high selectivity of solvation effects [Phys. Rev. Lett. 120, 066101 (2018)]. Going beyond the thermodynamic description, we utilize our novel potentiostat design to study reactions at electrochemical solid/liquid interfaces under controlled bias [Phys. Rev. Lett. 120, 246801 (2018)]. Focusing on one of the most corrosive system under wet corrosion, the new approach is shown to solve a problem that puzzled corrosion scientists for more than 150-years: what is the underlying mechanism of the experimentally observed link between H-evolution under anodic conditions and Mg dissolution.
9:48AM F45.00006: First-principles study of the hydrogen-bonding network in water at the biased electrode interface  JUHO LEE (Presenter), YONG-HOON KIM, Korea Adv Inst of Sci & Tech —
A crucial step for the development of next-generation electrochemical devices will be the understanding of the atomic and electronic structures of interfacial waters next to biased electrode surfaces. In this presentation, carrying out first-principles non-equilibrium electronic structure calculation within the multi-space constrained-search density functional theory (MS-DFT) formalism we have recently developed, we study the bias-dependent structural and electronic properties of the hydrogen-bonding network of water molecules at the gold electrode interface. Benchmarking the non-equilibrium force profile of a single water molecule next to the gold electrode obtained from non-equilibrium Green's function (NEGF) calculations, we confirm the practical equivalence between MS-DFT and DFT-NEGF. We also report the advantages of MS-DFT in view of electrochemical device simulations by providing (1) well-defined binding energies and (2) the electrochemical potential profiles. Analyzing the spatial profiles of the electrochemical potentials or quasi-Fermi levels at the gold-water interface at varying bias voltages, we extract several important insights into the nature of hydrogen bond network of liquid water at the biased electrochemical interfaces.

10:00AM F45.00007: Voltage-Dependent Cluster Expansions for Modeling Catalytic Electrochemical Interfaces in Solution Environments*  JAMES GOFF (Presenter), ISMAILA DABO, SUSAN BUTHAINA SINNOTT, Pennsylvania State University — The cluster expansion method provides the framework to represent functions of lattice configurations. We use this method to model energetics of solid-solution interfaces in electrochemical systems. Semi-local density functional theory calculations with implicit solvation are used to obtain effective cluster interactions that include local relaxations and the effects of the solvent. These calculations, in conjunction with electrochemical double layer models, provide the framework for voltage-dependent cluster expansions in a model electrochemical environment. We use these voltage-dependent cluster expansion to model faradaic charging at electrode-electrolyte interfaces, equilibrium configurations of surface alloys, and surface promotion in near-surface alloys. Preliminary voltage-dependent cluster expansion models of skin alloys suggest that amount of catalytically active sites highly sensitive to the applied potential.

Multiscale modeling of solvation effects in the Oxygen Evolution Reaction on TiO$_2$  LUCA BURSI (Presenter), NAIWRIT KARMODAK, OLIVIERO ANDREUSSI,
Department of Physics, University of North Texas — Development of sustainable energy generation and storage technologies able to satisfy the needs of modern society represents a major challenge for scientific research. Innovation here essentially rely on hydrogen (H) /oxygen (O) evolution reactions (ER) and /or oxidation of chemical fuels. OER generally represents the bottleneck of (photo)catalytic water splitting, as it requires high overpotentials. This has motivated an impressive search for sustainable high-performance electrocatalysts for OER, which identified TiO$_2$. Recently the microscopic mechanism of OER at TiO$_2$–water interface has been deeply studied. In particular, first principles simulations of rutile TiO$_2$ in explicit water [J. Phys. Chem. C, 123, 18567 (2019)] found the solvent to affect electrostatically the energetics at the interface, rather than to modify the H bond network. Such results pave the way for the use of implicit and hybrid solvation techniques in ab initio simulations of this system to further elucidate the effect of the solvent on OER, and specifically on its rate limiting step. To this aim, we exploit state-of-the-art implicit solvation schemes for condensed matter simulations, as implemented in the Environ plugin[http://www.quantum-environ.org] for Quantum ESPRESSO[http://www.quantum-espresso.org].

Ionic Structure in Dense Electrolytes Confined by Interfaces†  NASIM ANOUSHEH (Presenter), VIKRAM JADHAO, Indiana Univ - Bloomington — Recent surface force measurements have shown that the effective force between mica surfaces does not decay as sharply as predicted by mean-field models when the concentration of the confined electrolytes is high (around 2 M for NaCl). Motivated by these experiments, we use molecular dynamics simulations to extract the ionic structure in aqueous electrolytes confined by two interfaces. Ionic density profiles and contact-region densities are extracted for electrolytes confined between uncharged, charged, and polarizable interfaces at different concentrations with implicit-solvent models. Simulation results show that the net charge density in the contact region near charged surfaces exhibits a distinct trend with increase in interface separation for highly concentrated electrolyte systems (around 2 M for model NaCl) compared to electrolytes at low salt concentration. This behavior is further probed by varying ion sizes, interface charge density, ion valency, and interface polarizability, as well as by computing ion-ion pair correlation functions near the interface. Effects of explicit solvent molecules on the observed ionic structure are also discussed.

The Electrokinetic Transport of Multivalent Electrolytes: The Effect of Charge Inversion

ANDRES ROJANO (Presenter), Department of Chemical Engineering, Universidad de Concepcion, JENS HONORE WALTHER, Department of Mechanical Engineering, Technical University of Denmark, HARVEY A ZAMBRANO, Department of Mechanical Engineering, Universidad Tecnica Federico Santa Maria — Devices integrated by nanoconduits hold great potential for clinical and biochemical analysis due to amplified sensibility, faster response and increased portability. In nanoconduits, wherein the electrical double layer may occupy a considerable part of the channel, the hydrodynamics of multivalent electrolytes is highly influenced by interfacial electrokinetic phenomena, such as charge inversion (CI). We conduct atomistic simulations of an electrolyte solution which consists of water as solvent, chlorine as co-ion and different counter-ions, i.e., sodium, magnesium and aluminum. We model Electroosmotic (EOF), Poiseuille (PF) and Couette (CF) flow in silica nanochannels to probe the relation between CI and transport properties. In EOF, we observe that changes induced by CI in the electrokinetic driving force at the diffuse layer, significantly alter the velocity distributions. Moreover, cases of CF and PF flow show that the position of the shear plane is significantly altered by the presence of CI. We find that the nanoconfined electrolytes can be modeled as two immiscible fluids with different transport properties with the shear plane as dividing surface.

Session F46 GMAG DMP: Pyrochlores I 708 - Jinguang Cheng, Chinese Academy of Sciences - Tag(s): Focus
8:00AM F46.00001: Spherical Neutron Polarimetry and the Phase Diagram of Magnetically Dilute \( \text{Er}_2\text{Ti}_2\text{O}_7 \)

CONNOR BUHARIWALLA (Presenter), Department of Physics & Astronomy, McMaster University, JONATHAN GAUDET, Institute for Quantum Matter and Department of Physics and Astronomy, Johns Hopkins University, CISSY SUEN, Department of Physics & Astronomy, McMaster University, NAVID QURESHI, ANNE STUNAULT, Institut Laue-Langevin, TIMOTHY MUNSIE, Department of Physics & Astronomy, McMaster University, HANNA DABKOWSKA, Brockhouse Institute For Materials Research, McMaster University, BRUCE D. GAULIN, Department of Physics & Astronomy, McMaster University —

The ground state of XY pyrochlore antiferromagnet \( \text{Er}_2\text{Ti}_2\text{O}_7 \) has been a rich topic of research due to the selection of a non-coplanar \( k=0 \) magnetically ordered state \( \psi_2 \) through order by disorder. Several proposed mechanisms account for this selection of \( \psi_2 \) over the coplanar \( \psi_3 \), the alternate basis state of the \( \Gamma_5 \) irreducible representation. Recent theory work has proposed that magnetic dilution that will lead to an instability in the ground state selection, resulting in a \( \psi_3 \) ground state for a dilute \( \text{Er}_2\text{Ti}_2\text{O}_7 \). Through systematic substitution of non-magnetic \( \text{Y}^{3+} \) on the \( \text{Er}^{3+} \) site, we have probed the effect of such dilution with samples of 5%, 10%, and 20% \( \text{Y}^{3+} \). While the magnetic structures of \( \psi_2 \) and \( \psi_3 \) are indistinguishable in an unpolarized neutron scattering measurement, the contrast is clear using spherical neutron polarimetry (SNP). In this talk, I will present the results of our SNP study of these 3 diluted samples, following our previous work using inelastic neutron scattering.

8:12AM F46.00002: Magnetic phase competition in the rare-earth pyrochlore \( \text{Er}_2\text{Sn}_2\text{O}_7 \)*

DANIELLE R YAHNE (Presenter), Department of Physics, Colorado State University, LIURUKARA D SANJEEWA, Materials Science and Technology Division, Oak Ridge National Laboratory, JOSEPH KOLIS, Department of Chemistry, Clemson University, LUDOVIC DC JAUBERT, CRNS, LOMA, University of Bordeaux, DARREN PEREIRA, Department of Physics, University of Waterloo, MATTHEW JOHN ENJALRAN, Department of Physics, Southern Connecticut State University, MICHEL J P GINGRAS, Department of Physics, University of Waterloo, KATE ROSS, Department of Physics, Colorado State University — Rare-earth pyrochlore oxides \( (\text{A}_2\text{B}_2\text{O}_7) \) can host a wealth of exotic phenomena due to geometric- and exchange-frustration. \( \text{Er}_2\text{Sn}_2\text{O}_7 \) is especially interesting in this regard as, based on available estimates of the exchange interactions, it lies near a phase boundary in the anisotropic exchange parameter space, between two antiferromagnetic states: the Palmer-Chalker states (where \( \text{Er}_2\text{Sn}_2\text{O}_7 \) orders) and the \( \Gamma_5 \) states. A natural tool to probe such multi-phase competition is the application of an external magnetic field, but until now the absence of single crystals made such approach difficult to analyze. In this talk, we report specific heat measurements on single crystals of \( \text{Er}_2\text{Sn}_2\text{O}_7 \) under fields applied along the three high symmetry directions, \([111]\), \([110]\), and \([100]\). Each field direction provides a distinct phase diagram, but with the shared feature that one (sometimes even two) reentrant lobe(s) appear above a threshold field of 0.2 T. The nature of this reentrance can be understood semi-quantitatively through classical Monte-Carlo simulations and mean field theory, the details of which will be described in a presentation by D. Pereira.

*DE-SC0020071
Rare-earth pyrochlore magnets are known to exhibit a variety of exotic phenomena. The dipolar XY pyrochlore magnets in particular act as playgrounds for effects like order-by-disorder, multiphase competition, and strong quantum fluctuations. $\text{Er}_2\text{Sn}_2\text{O}_7$, a member of the XY pyrochlore family, has recently been synthesized as a single crystal and studied under a magnetic field. The resulting $(H,T)$ phase diagram reveals multiple reentrant lobes for fields applied in the [100], [110], and [111] directions. In this talk, I will discuss our efforts to understand these reentrant phenomena from the theoretical front, drawing from variational mean-field theory, classical Monte Carlo simulations, and classical spin wave analysis. I will argue that the reentrant lobes are related to a complex multiphase competition, in which the changing ground state degeneracy in a field is associated with the apparition of soft mode excitations. We expect our reasoning to be applicable to other rare-earth pyrochlores and frustrated magnets in general, especially for systems with a discrete ground state degeneracy.
High pressure synthesis and characterization of $R_2Pt_2O_7$ pyrochlores

[Invited] JINGUANG CHENG (Presenter), Institute of Physics, Chinese Academy of Sciences — Rare-earth pyrochlore oxides $R_2B_2O_7$ constitute a versatile material platform to study a wide range of magnetic phenomena including order by disorder, geometric frustration, spin ice, and spin freezing. While being non-magnetic, the B-site cations are thought to be able to influence the magnetic properties of these compound primarily through the chemical pressure, which has been well demonstrated in the comparative studies of $R_2B_2O_7$ (B = Ge, Ti, Sn) through varying the radius of the B-site cation. The high-pressure synthesis of $R_2Ge_2O_7$ with the cubic pyrochlore structure is essential for these studies. Recently, we have further extended our research to the $R_2Pt_2O_7$ system, which can only be stabilized under high-pressure conditions. Unlike the previously studied $R_2B_2O_7$ with the B site occupied by either a 3d transition-metal like Ti or a p-block metal such as Ge and Sn, the Pt$^{4+}$ has spatially more extended 5d orbitals and thus enhanced Pt 5d-O 2p hybridizations that might modify the local anisotropic exchange interactions of R3+ ions. Such an effect beyond the steric effect has not been taken into account in previous studies on the geometrically frustrated magnets. Indeed, we found enhanced magnetic ordering temperature in Gd$_2$Pt$_2$O$_7$ due to presence of extra superexchange pathways through the empty Pt-e$_g$ orbitals [1]. We also revealed distinct influences on the anisotropic exchange interactions in the XY pyrochlores Er$_2$Pt$_2$O$_7$ and Yb$_2$Pt$_2$O$_7$ [2]. In addition, we observed unusual behaviors in the classical spin ice Ho$_2$Pt$_2$O$_7$ [3].

**9:12AM F46.00005: Single crystal neutron scattering study of the pyrochlore Yb$_2$Ge$_2$O$_7$*\(^*\)**

COLIN SARKIS (Presenter), Colorado State University, JEFFREY RAU, University of Windsor, DUMINDA SANJEEWA, MATTHEW POWELL, JOSEPH KOLIS, Clemson University, JONATHAN J MARBEY, STEPHEN HILL, Florida State University, JOSE RODRIGUEZ-RIVERA, NIST Center for Neutron Scattering, HARIKRISHNAN S NAIR, University of Texas El Paso, MICHEL J P GINGRAS, University of Waterloo, KATE ROSS, Colorado State University — Rare earth pyrochlore oxides have been found to be hosts for a wide breadth of exotic phenomena based on strong frustration. Previous single crystal studies of Yb$_2$Ti$_2$O$_7$ have established that it forms a ferromagnetic (FM) ground state, but lies near a classical phase boundary between FM and antiferromagnetic (AFM) states. Meanwhile, powder neutron scattering studies of Yb$_2$Ge$_2$O$_7$ show it selects the AFM state. Despite this difference, these Yb pyrochlores share the same unusual spin dynamics in zero field. Further experimental progress on Yb$_2$Ge$_2$O$_7$ has been stymied by a lack of large single crystal samples. We report inelastic neutron scattering measurements on single crystals of Yb$_2$Ge$_2$O$_7$ grown by a hydrothermal method. We have used the field-polarized spin waves to determine the exchange parameters for Yb$_2$Ge$_2$O$_7$. The g-tensor was independently determined from electron paramagnetic resonance on a Lu$_{1.98}$Yb$_{0.02}$Ge$_2$O$_7$ sample in order to enable an unambiguous determination of these parameters. Our analysis and theoretical modeling show that Yb$_2$Ge$_2$O$_7$ lies in extreme proximity to the classical phase boundary between the AFM and FM phase, lending strong support to the notion of phase competition as playing a key role in the Yb pyrochlore family.

*DOE:DE-SC0020071

**9:24AM F46.00006: Orientation Dependence of the Magnetic Phase Diagram of Yb$_2$Ti$_2$O$_7$*\(^*\)**

STEFFEN SÄUBERT (Presenter), Colorado State University, ALLEN SCHEIE, Oak Ridge National Laboratory, CHRISTOPHER DUVINAGE, Technical University of Munich, JONAS KINDERVATER, SHU ZHANG, Johns Hopkins University, HITESH CHANGLANI, Florida State University, GUANGYONG XU, NIST Center for Neutron Research, SEYED KOOHPAYEH, OLEG TCHERNYSHYOV, COLLIN LESLIE BROHOLM, Johns Hopkins University, CHRISTIAN PFLEIDERER, Technical University of Munich — We present the orientation dependence of the magnetic phase diagram of stoichiometric Yb$_2$Ti$_2$O$_7$ using four experimental probes: magnetization, heat capacity, susceptibility, and neutron scattering. The magnetic phase diagram for fields along $\langle 110 \rangle$ shows dramatic reentrant character (similar to fields along $\langle 111 \rangle$), whereas for fields along $\langle 100 \rangle$, the upper phase boundary collapses and the system enters a field polarized state for small applied fields. By comparing this data to theoretical models, we show that Yb$_2$Ti$_2$O$_7$ is a cubic ferromagnet that is qualitatively described by Landau theory, but a comparison of upper critical fields show that the system cannot be described only by classical mean-field considerations, more that it is subject to collective or quantum effects.

9:36AM F46.00007: Exploring the influence of disorder on magnetic moment fragmentation*
ELI ZOGHLIN (Presenter), JULIAN L SCHMEHR, STEPHEN WILSON, University of California, Santa Barbara — Recent neutron scattering measurements demonstrating concurrent all-in-all-out antiferromagnetic order and pinch-point diffuse scattering in the pyrochlore Nd2Zr2O7 provide compelling evidence for the phenomenon of magnetic moment fragmentation\(^1\). However, the influence of chemical and crystallographic disorder native to the pyrochlore lattice on the formation of this underlying state remains poorly understood. Here we present an experimental exploration of the role of native disorder on the features associated with spin fragmentation in Nd2Zr2O7. Neutron scattering and thermodynamic measurements of crystals with varying defect concentrations, examined by electron microprobe analysis, are studied to resolve the impact of disorder on the ground state of this material.

*We gratefully acknowledge funding from the W.M. Keck Foundation.

9:48AM F46.00008: Magnetization plateaus of the quantum pyrochlore Heisenberg antiferromagnet*
SANTANU PAL (Presenter), Department of Physics, Indian Inst of Tech-Bombay, Powai, Maharashtra, India, SIDDHARTHA LAL, Department of Physical Sciences, IISER Kolkata, Mohanpur, India — We predict magnetization plateaus ground states for S = 1/2 Heisenberg antiferromagnets on pyrochlore lattices by formulating arguments based on gauge and spin-parity transformations. We derive a twist operator appropriate to the pyrochlore lattice, and show that it is equivalent to a large gauge transformation. Invariance under this large gauge transformation indicates the sensitivity of the ground state to changes in boundary conditions. This leads to the formulation of an Oshikawa-Yamanaka-Affleck–like criterion at finite external magnetic field, enabling the prediction of plateaus in the magnetization versus field diagram. We also develop an analysis based on the spin-parity operator, leading to a condition from which identical predictions are obtained of magnetization plateaus ground states. Both analyses are based on the non-local nature of the transformations, and rely only on the symmetries of the Hamiltonian. This suggests that the plateaus ground states can possess properties arising from non-local entanglement between the spins.

*We acknowledge CSIR, Govt. of India and IISER Kolkata for financial support.
Magnetism of classical pyrochlore antiferromagnet Na$_3$Mn(CO$_3$)$_2$Cl*

KAZUHIRO NAWA (Presenter), DAISUKE OKUYAMA, Institute of Multidisciplinary Research for Advanced Materials, Tohoku University, MAXIM AVDEEV, Australian Nuclear Science and Technology Organisation, HIROYUKI NOJIRI, Institute for Materials Research, Tohoku University, MASAHIRO YOSHIDA, DAICHI UETA, HIDEKI YOSHIZAWA, Institute for Solid State Physics, The University of Tokyo, TAKU SATO, Institute of Multidisciplinary Research for Advanced Materials, Tohoku University — Pyrochlore antiferromagnets have attracted interests in terms of unconventional ground states and spin excitations owing to competing interactions. When its magnetism is dominated by classical spins coupled by Heisenberg interactions, a spin liquid state is expected as its ground state because of infinite degeneracy in the ground state (R. Moessner and J. T. Chalker, Phys. Rev. Lett. 80, 2929 (1998); Phys. Rev. B 58, 12049 (1998)). In this research, we report structural and magnetic properties together with low-temperature neutron diffraction patterns on a new pyrochlore antiferromagnet Na$_3$Mn(CO$_3$)$_2$Cl. The structure of Na$_3$Mn(CO$_3$)$_2$Cl is isotypic with that of the Co-analogue Na$_3$Co(CO$_3$)$_2$Cl, which exhibits all-in-all-out magnetic order below 1.5 K (Z. Fu et al., Phys. Rev. B 87, 214406 (2013)). On the other hand, no magnetic Bragg peak indicating a magnetic order was detected down to 0.05 K in Na$_3$Mn(CO$_3$)$_2$Cl. A high degeneracy near the ground state is suggested by a magnetic entropy estimated from heat capacity experiments and enhancement of diffuse scattering from neutron diffraction experiments.

*This work was supported by a Grant-In-Aid for Scientific Research (No. 17K18744) from MEXT of Japan, and Advanced Material Research Award of Hatano Fundation.

Magnetic properties of distorted pyrochlore lattice Mn$_2$(OD)$_3$X (X = Cl, Br)  
MASATO HAGIHALA (Presenter), KEK, High Energy Accelerator Research Organization, X.G. ZHENG, Saga University, TAKASHI KAMIYAMA, KEK, High Energy Accelerator Research Organization — Atacamite family, of which component is M$_2$(OH)$_3$X (M:3dmetal, X:halogen) forms geometrical frustrated lattice, and behave in an exotic magnetic states; the ground state of clinoatacamite is coexistence of long-range order and strong spin fluctuation[1]. Atacamite(Cu$_2$(OH)$_3$Cl), which is distorted pyrochlore, reported as antiferromagnetic transition at $T_N = 9$ K[2]. Recently, it is reported that atacamite is regarded as $S = 1/2$ sawtooth chains system, and its magnetic order is represented $k = (1/2 \ 0\ 1/2)$ [3,4]. We remark atacamite type compounds Mn$_2$(OH)$_3$X. Both compounds have two successive transitions below $T \sim 3K$ [5]. Our neutron experiment revealed different magnetic orders on these four phases. The ground state of Mn$_2$(OD)$_3$Br is also represented $k = (1/2 \ 0\ 1/2)$, its magnetic structure have two kind of spin configurations on the saw tooth chains. Spin configurations on other three phases are modulated along the $a$ axis. Successive transition and different $k$ vector imply stronger frustration effect than atacamite. [1] X. G. Zheng et al., PRL 95, 057201 (2005). [2] X. G. Zheng et al., PRB 71, 174404 (2005). [3] L. Heinze et al., Physica B 536, 377-378 (2018). [4] L. Heinze et al., arXiv:1904.07820v1. [5] M. Hagihala et al., J. Phys.: Cond. Matt. 19, 145281 (2007).
Magnetometry and transport studies of single crystal pyrochlore iridates*  MATTHEW PEARCE (Presenter), KATHRIN GOETZE, PAUL GODDARD, MARTIN LEES, Department of Physics, University of Warwick, DHARMALINGAM PRABHAKARAN, ANDREW T BOOTHROYD, Department of Physics, University of Oxford, TYCHO SIKKENK, Department of Physics, Utrecht University, ATTILA SZABO, CLAUDIO CASTELNOVO, TCM, University of Cambridge — Magnetic pyrochlore oxides have attracted significant interest due to their geometrically frustrated lattice, which acts to suppress long range magnetic order and leads to a variety of unusual magnetic ground states and exotic excitations.

Some of the most studied pyrochlores are the spin ices $\text{Ho}_2\text{Ti}_2\text{O}_7$ and $\text{Dy}_2\text{Ti}_2\text{O}_7$ – here the rare earth ions are ferromagnetic whilst the Ti is nonmagnetic. Recently, the pyrochlore iridates ($R_2\text{Ir}_2\text{O}_7$, $R =$ rare earth) have risen to prominence. Here, both the rare earth and the Ir are magnetic; the added complexity afforded by the Ir magnetism may be expected to yield a rich variety of physical phenomena. For instance, most of the pyrochlore iridates exhibit a metal to insulator transition which accompanies the ordering of the Ir into an ‘all-in-all-out’ configuration.

Here we report on magnetisation and resistivity measurements on new single crystals of pyrochlore iridates. We present a systematic study of the evolution of these properties with magnetic field, temperature and angle. Supported by Monte Carlo simulations we present our interpretation of the highly anisotropic and hysteretic behaviour observed as well as its wider significance.

*This project has received funding from the European Research Council (grant no. 681260). We also thank the EPSRC.

Magnetisation and monopole density response to applied magnetic fields in rare earth pyrochlore iridates  ATTILA SZABO, TYCHO SIKKENK, CLAUDIO CASTELNOVO (Presenter), Univ of Cambridge, MATTHEW PEARCE, KATHRIN GOETZE, MARTIN LEES, University of Warwick, DHARMALINGAM PRABHAKARAN, ANDREW T BOOTHROYD, University of Oxford, PAUL GODDARD, University of Warwick — We investigate the behaviour of rare earth pyrochlore iridates $\text{Dy}_2\text{Ir}_2\text{O}_7$ and $\text{Ho}_2\text{Ir}_2\text{O}_7$ using dipolar Monte Carlo simulations for the rare earth moments and an effective representation of the Ir moments as local fields [Lefrancois et al, Nat. Comm. 2017]. We study in particular how the magnetisation and defect population respond to externally applied magnetic fields along different crystal directions. We uncover an intriguing interplay between the rare earth moments and the correlations in the underlying Ir moments, and we comment on their possible relevance to experimental results.
Cd$_2$Re$_2$O$_7$ is the first superconductor in pyrochlore oxide family and a prototype compound for spontaneous inversion symmetry breaking with strong spin-orbit coupling. The inversion breaking transition near 200K from centrosymmetric cubic phase to the noncentrosymmetric tetragonal phase. Another structural transition occurs at 120K. However, the distortions are very small and identified controversially in different measurement techniques. Quantum oscillation is very sensitive to the differences of the structures and ideally to study the inversion symmetry breaking from spin splitting Fermi surfaces. In this talk, we will discuss the Fermiology of Cd$_2$Re$_2$O$_7$ by torque magnetometry and compare with the density functional calculations.
In this talk, we will explore the use of permalloy ($\text{Ni}_{80}\text{Fe}_{20}$) thin films in hybrid magnon systems. Permalloy is a classical metallic ferromagnet with well-known magnetic dynamic properties and is easy to grow and integrate into complex devices. In the first part, we demonstrate strong coupling of magnons in a permalloy thin-film device to the microwave photons in a coplanar superconducting resonator\(^6\), via magnetic dipolar interaction. In the second part, we show strong coupling of permalloy magnons to the spatially nonuniform magnon modes of a YIG film via interfacial coupling\(^7\). Besides the interfacial exchange coupling acting as a field-like torque, we also show evidence that spin pumping creates a damping-like coupling torque. This torque leads to an increase in line width for the out-of-phase hybrid mode and a reduction for the in-phase hybrid mode. Our results provide new pathways for implementing on-chip magnonic devices with efficient and coherent information transducers.

Strong Interlayer Magnon-Magnon Coupling in Magnetic Hybrid Nanostructures

JILEI CHEN (Presenter), CHUANPU LIU, BeiHang University, TAO LIU, Physics Department, Colorado State University, YANG XIAO, Nanhang University, KE XIA, Beijing Normal University, GERRIT BAUER, Tohoku University, MINGZHONG WU, Physics Department, Colorado State University, HAIMING YU, BeiHang University — Strong couplings between magnons and photons have recently attracted lots of attention due to potential applications in quantum computing by utilizing coherent couplings between spins and superconducting qubits. Here, I will present our recent experimental results on strong interlayer magnon-magnon coupling in an on-chip nanomagnonic device at room temperature [1]. Ferromagnetic nanowire arrays are integrated on a 20-nm-thick yttrium iron garnet (YIG) thin film strip. Large anticrossing gaps up to 1.58 GHz are observed between the ferromagnetic resonance of the nanowires and the in-plane standing spin waves of the YIG film. The coupling strength is tunable by the magnetic configuration, allowing the coherent control of magnonic devices.

8:48AM F47.00003: Introducing Coherent Time Control to Cavity Magnon Polartion Modes
TIM WOLZ (Presenter), ALEXANDER STEHLI, ANDRE SCHNEIDER, Karlsruhe Institute of Technology, ISABELLA BOVENTER, Institute of Physics, Johannes Gutenberg University Mainz, RAIR MACEDO, James Watt School of Engineering, University of Glasgow, ALEXEY V. USTINOV, Karlsruhe Institute of Technology, MATHIAS KLAUE, Institute of Physics, Johannes Gutenberg University Mainz, MARTIN WEIDES, James Watt School of Engineering, University of Glasgow — By connecting light to magnetism, cavity-magnon-polaritons (CMPs) [1-3] can link quantum computation to spintronics. Consequently, CMP-based information processing devices have thrived over the last years, but have almost exclusively been investigated with single-tone spectroscopy. However, universal computing applications will require a dynamic control of the CMP on demand and within nanoseconds. In this work [4], we perform fast manipulations of the different CMP modes with independent but coherent pulses to the cavity and magnon system. We change the state of the CMP from the energy exchanging beat mode to its normal modes and further demonstrate two fundamental examples of coherent manipulation: First, a dynamic control over the appearance of magnon-Rabi oscillations, i.e., energy exchange, and second, energy extraction by applying an anti-phase drive to the magnon. Our results show a promising approach to control different building blocks for a quantum internet and pave the way for further magnon-based quantum computing research.

9:00AM F47.00004: Nanoscale Detection of Magnon Excitations with Variable Wavevectors Through a Quantum Spin Sensor
ERIC LEE-WONG, University of California, San Diego, RUOLAN XUE, Harvard University, FEIYANG YE, University of California, San Diego, ANDREAS KREISEL, University of Leipzig, TOENO VAN DER SAR, Delft University of Technology, AMIR YACOBY, Harvard University, CHUNHUI DU (Presenter), University of California, San Diego — Control and manipulation of pure spin currents in magnetic insulators has been a central focus of modern spintronic research. Building on the transformative nitrogen vacancy (NV) based quantum sensing platform, we have achieved local detection of a range of spin wave modes in magnetic insulator \( \text{Y}_3\text{Fe}_5\text{O}_{12} \) thin films over a 100-nanometer length scale. Through the multi-magnon scattering process, the excited spin waves generate fluctuating magnetic fields at the NV electron spin resonance frequencies, accelerating the relaxation of the NV spin. By measuring the variation of the emitted photoluminescence of the NV center, the detailed information of the magnon modes can be optically accessed, providing a unique window to reveal the local magnetic properties of the studied materials. Our findings highlight the significant opportunities offered by NV spin quantum sensors in exploring nanoscale spin dynamics of emergent spintronic systems.
9:12AM F47.00005: Spin wave resonance study in a series of etched GaMnAsP films  XINYU LIU (Presenter), Physics, University of Notre Dame, SEUL-KI BAC, SANGHOON LEE, Physics, Korea University, MALGORZATA DOBROWOLSKA, JACEK K. FURDYNA, Physics, University of Notre Dame, HENRYK PUSZKARSKI, PIOTR TOMCZAK, Physics, Adam Mickiewicz University — Although ferromagnetic semiconductor films have already been investigated for the last two decades, some fundamental issues still puzzle the researchers in this field. One of these issues is how the magnetic anisotropy field distributes along the growth direction. In order to resolve this issue in a 108-nm GaMnAsP film, a series of etched samples formed by wet-etching this GaMnAsP film were studied by XRD, SQUID and FMR. The thicknesses of the etched GaMnAsP films were determined by XRD measurements, using the oscillations observed in ω-2θ scans. The XRD peaks from GaMnAsP films are also used to determine the Mn and P contents along the growth direction. Magnetizations of the films are measured by SQUID as a function of field and temperature. FMR measurements were carried out at 4K as function of field orientation, using both out-of-plane and in-plane geometries. A series of spin wave modes are observed when field is applied in the plane of film, as well a critical angle phenomenon is found in specific resonance configurations. The angular dependence of spin wave modes will be analyzed using newly reported spherical surface pinning model in order to map the surface free energy. The results will be summarized as a function of film thickness for all etched samples.

9:24AM F47.00006: Strong angle dependence of auto-oscillating spin wave multi-modes in constricted Py/Pt bilayers  INHEE LEE (Presenter), CHI ZHANG, SIMRANJEET SINGH, BRENDAN MCCULLIAN, P CHRIS HAMMEL, Ohio State Univ - Columbus — Spin-orbit torque driven auto-oscillators (AO) in constricted bilayers can be highly coherent and tunable, even at room temperature. However, the dissipation mechanisms of AO confined by a constriction remain unclear. We have studied the dependence of several AO modes on the angle between the current flow and an in-plane applied magnetic field in a 0.6 μm x 1 μm Py/Pt bilayer. We observe considerable changes in the size, number, and distribution of modes as the angle varies. The spatial profiles of the modes are identified using micromagnetic simulation, and classified into three types: edge, center-like, and their combination. We also characterize the AO modes in terms of resonance frequency, linewidth and power. Beyond a threshold current, the power in the lowest order mode saturates and its linewidth increases. However, this coincides with enhanced excitation of higher order modes such that the power summed over all modes continues to grow with current. We achieve ~ 8 MHz minimum linewidth and ~ 0.5 pW maximum power at 77 K from the lowest order mode at an angle of 65 degree, though below 120 K, the improvement of the mode for the narrower linewidth and the stronger power with decreasing temperature is reduced.
Influence of ferromagnetic films surface properties on spin wave modes

RODRIGO ARIAS (Presenter), IGNACIO ARMIJO, Physics, Universidad de Chile — The frequencies of propagating spin waves in ferromagnetic films may be determined experimentally with some precision, and reflect the surface properties of the films. In particular, if the surface properties break symmetries between both surfaces, there will be frequency non-reciprocity between spin waves that travel in different directions. Furthermore, there is possible shape non-reciprocity of the spin waves even for symmetric films. Thus, in order to relate surface properties to the behavior of spin waves, we study theoretically, within the micro magnetic approximation, spin wave modes under obliquely applied magnetic fields to the film, since in this case the surface properties have a more clear influence in the spin wave properties. For this case the equilibrium magnetization is non-uniform, it deflects close to the surfaces, due to effective surface boundary conditions that model local surface fields. We use the Extinction-Green theorems to determine the spin wave modes, solving numerically differential equations along the transverse direction for the so-called auxiliary functions, and we interpret these numerical results by use of the WKB approximation.

Quantitative Study of Spin Wave Chirality in Obliquely Magnetized Magnetic Films

CODY TREVILLIAN (Presenter), VASYL S TYBERKEVYCH, Oakland University — Dipole-dipole interaction in thin magnetic films leads to formation of parity-breaking (i.e., chiral) spin wave (SW) modes, such as, e.g., chiral magnetostatic surface SW (CMSSW) [1] & heterosymmetric SW (HSSW) [2] having a number of unique properties. However, a general theory of the origin of chiral spin wave formation & their chiral properties in obliquely magnetized magnetic films (OMMF) remains absent. Here, we propose a quantitative measure of SW chirality, $C_n = 1 - \left| \langle P \rangle_n \right|$, where $\langle P \rangle_n$ is the expected value of the parity operator for the $n^{th}$ SW mode. Using Kalinikos-Slavin's theory of SW spectrum in OMMF [3], we performed quantitative study of formation of chiral SWs. We show that total parity $\sum_n \langle P \rangle_n$ of all SW modes is approximately conserved, which implies that SW modes acquire chiral properties in pairs through the “parity exchange” mechanism. In particular, we demonstrate formation of strongly chiral modes at odd crossing points of SW spectrum & show that chirality of both CMSSW & HSSW is a result of “parity exchange” between two lowest symmetric & antisymmetric SW modes.

10:00AM F47.00009: Probing phase transition and anisotropy in magnetic insulator based heterostructures employing magnon spin currents  KINGSHUK MALLICK (Presenter), ADITYA A WAGH, Indian Institute of Science - Dept of Physics, ADRIAN IONESCU, CRISPIN H.W. BARNES, Cavendish Laboratory, Physics Department, University of Cambridge, P.S. ANIL KUMAR, Indian Institute of Science - Dept of Physics — Many reports have explored the temperature dependence of Longitudinal Spin Seebeck Effect (LSSE) in insulating magnets. However, there has been a longstanding disparity between theory and experimental evidence with regards to the nature of power law decay of the LSSE while approaching the ferromagnetic phase transition temperature ($T_C$). We investigate bilayers of Pt/La$_2$NiMnO$_6$ (LNMO) and Pt/EuO$_{1-X}$, both predicted to be promising candidates for spintronics. Our findings reveal that the signal near $T_C$ can be fitted to a power law of the form $(T_C-T)^p$. We explain our results based on the magnon-driven thermal spin pumping theory. We comprehensively demonstrate correlation between the critical exponents of LSSE and magnetization for both FMs. Interestingly, the exponent, $p$, remained invariant upon varying the crystallinity in LNMO. In contrast, Spin Hall Magnetoresistance (SMR) measurements on epitaxial LNMO, exhibit distinctly different features. The observed behavior in epitaxial films appears to be dominated by the interface magnetic anisotropy. In addition, we observe SMR and Anisotropic Magnetoresistance (AMR) in Pt/EuO$_{1-X}$ thin films. We deduce possible explanations based on the temperature dependence of EuO$_{1-X}$ bandstructure and spin mixing conductance of the Pt/EuO$_{1-X}$ interface.

10:12AM F47.00010: Tuning entanglement by squeezing magnons in anisotropic magnets*  JI ZOU (Presenter), University of California, Los Angeles, SE KWON KIM, Department of Physics and Astronomy, University of Missouri, YAROSLAV TSERKOVNYAK, University of California, Los Angeles — We theoretically study the entanglement between two arbitrary spins in a magnetic material, where magnons naturally form a general squeezed coherent state, in the presence of an applied magnetic field and axial anisotropies. Employing concurrence as a measure of entanglement, we demonstrate that spins are generally entangled in thermodynamic equilibrium, with the amount of entanglement controlled by the external fields and anisotropies. As a result, the magnetic medium can serve as a resource to store and process quantum information. We, furthermore, show that the entanglement can jump discontinuously when decreasing the transverse magnetic field. This tunable entanglement can be potentially used as an efficient switch in quantum-information processing tasks.

10:24AM F47.00011: Electron-magnon scattering and magnon generated chiral charge and spin pumping from time-dependent-quantum-transport/classical-micromagnetics approach*  

ABHIN SURESH (Presenter), BRANISLAV NIKOLIC, Univ of Delaware — In this study, we employ recently developed [M. D. Petrovic et. al., Phys. Rev. Appl. 10, 054038 2018] multiscale time-dependent-quantum-transport/classical-micromagnetics formalism (TDNEGF-LLG) to simulate how spin-polarized steady state current of electrons interacts with a magnon modelled as a classical spin wave. We investigate electronic spin and charge currents generated by the excitation of a single frequency spin wave in a one-dimensional finite size magnetic nanowire composed of classical local magnetic moments precessing around the anisotropy axis while the phase of the precession of adjacent moments varies harmonically over the wavelength of spin wave with uniform precession cone angle. We show that spin wave hosted in the middle of two metallic leads pumps chiral electronic spin and charge currents into the leads, which can be flipped by reversing the direction of magnonic spin current carried by the spin wave. When steady spin-polarized electronic charge current is injected from the left lead into the region hosting the spin wave, we observed that outgoing electronic charge and spin currents in the right lead can be reduced or enhanced, depending on the direction of magnonic spin current.

10:36AM F47.00012: Investigation of the magnon dispersion in Lu$_2$V$_2$O$_7$ and magnon Weyl point*  

SEUNGHWAN DO (Presenter), Materials Science and Technology Division, Oak Ridge National Lab, JEFFREY RAU, Department of Physics, University of Windsor, HASITHA SURIYA ARACHCHIGE, Department of Physics, University of Tennessee, BINOD K. RAI, Materials Science and Technology Division, Oak Ridge National Lab, GABRIELE SALA, VICTOR R. FANELLI, MATTHEW STONE, Neutron Scattering Division, Oak Ridge National Lab, QING HUANG, HAIDONG ZHOU, Department of Physics, University of Tennessee, MARK D LUMSDEN, Neutron Scattering Division, Oak Ridge National Lab, ANDREW D CHRISTIANSON, Materials Science and Technology Division, Oak Ridge National Lab — The ferromagnetic pyrochlore lattice with Dzyaloshinskii-Moriya (DM) interactions has attracted much attention due to predicted Weyl points in the magnon spectrum [1,2]. The pyrochlore Lu$_2$V$_2$O$_7$ has been suggested as a strong candidate to realize the concept [2]; it has a ferromagnetic ground state below $T_C \approx 69.5$ K [3] and the presence of a magnon Hall effect indicates a strong DM interaction [4]. We use inelastic neutron scattering to examine the spin wave excitations in the compound. These measurements enable us to detect sharp magnon dispersions that are well modeled with linear spin wave theory.

Spin Seebeck Effect in Helimagnetic Cu₂OSeO₃: Test of Bulk Magnon Spin Current Theory* ARTEM AKOPYAN (Presenter), NARAYAN PRASAI, Physics, Univ of Miami, BENJAMIN TRUMP, GUY G. MARCUS, TYREL MCQUEEN, Chemistry, Johns Hopkins Univ, JOSHUA COHN, Physics, Univ of Miami — Cu₂OSeO₃ exhibits the largest magnon thermal conductivity of any known ferro- or ferrimagnet. Here we report temperature (T) and magnetic field-dependent measurements of magnon thermal conductivity (κₘ) and longitudinal spin Seebeck coefficient (S_LSSE) in 10-nm Pt/Cu₂OSeO₃ heterostructures for 1~K ≤ T ≤ 15~K. Measurements for three different specimens, having spin-mixing conductances that vary by more than an order of magnitude, demonstrate a relationship between κₘ and S_LSSE in good agreement with bulk magnon spin current theory.

Session F48 DCMP: Superconductivity: General Theory Mile High Ballroom 1A - Khadijeh Najafi, Virginia Tech

How Alfven's theorem explains the Meissner effect JORGE HIRSCH (Presenter), University of California, San Diego — Alfven's theorem states that in a perfectly conducting fluid magnetic field lines move with the fluid without dissipation. When a metal becomes superconducting in the presence of a magnetic field, magnetic field lines move from the interior to the surface (Meissner effect) in a reversible way. This indicates that a perfectly conducting fluid is flowing outward. I explain the nature of this fluid and show that it carries neither charge nor mass, but carries effective mass. This implies that the effective mass of carriers is lowered when a system goes from the normal to the superconducting state, which agrees with the prediction of the unconventional theory of hole superconductivity, with optical and photoemission experiments in some superconducting materials, and with Bardeen's first theory of superconductivity. The 60-year old conventional understanding of the Meissner effect ignores Alfven's theorem and for that reason I argue that it does not provide a valid understanding of real superconductors.
8:12AM F48.00002: Superconductivity induced by fluctuations of momentum-based multipoles
SHUNTARO SUMITA (Presenter), YOUICHI YANASE, Department of Physics, Kyoto University — Recent studies of superconductivity have focused on spin fluctuation, instead of electron-phonon coupling, as an origin of attractive interaction between electrons. On the other hand, a multipole order, which represents electrons' degrees of freedom in strongly spin-orbit coupled systems, is attracting much attention. Therefore, it is helpful for understanding unconventional superconductivity to consider “superconductivity induced by multipole fluctuations,” as an extension of spin-fluctuation-mediated superconductivity. Indeed, previous works have studied superconductivity induced by fluctuations of odd-parity electric multipole orders in isotropic systems.
In this study, we investigate superconductivity induced by fluctuations odd-parity magnetic multipoles, aiming at good understanding of multipole-fluctuation-mediated superconductivity. Furthermore, this study focuses on the effect of crystalline electric fields (CEF) using the classification theory of multipoles, while the previous studies simply assume isotropic systems. As a result, we suggest that a nodal extended s-wave pairing may be favored by an odd-parity magnetic multipole fluctuation under CEF.
*JSPS KAKENHI Grants No. 17J09908

8:24AM F48.00003: Multiple solutions of pairing gap equation in quantum critical metals.
YI-MING WU (Presenter), University of Minnesota, ARTEM G ABANOV, Physics, Texas A&M U, YUXUAN WANG, Physics, U of Florida, ANDREY CHUBUKOV, University of Minnesota — We use Eliashberg theory to analyze superconductivity for a class of quantum-critical models of itinerant fermions interacting with collective massless bosons, with varying scaling dimension γ of a boson (the γ model). A conventional wisdom holds that there is a single $T_c$ for the pairing in a given symmetry channel. We find in this study that at the critical point the situation is different: the linearized gap equation has a cascade of solutions at $T=T_c^{(n)}$. These solutions have the same spatial symmetry, but they are topologically distinct by the number of sign changes as functions of Matsubara frequency. The transition temperatures $T_c^{(n)}$ decrease exponentially with increasing number of nodes $n$, and the largest $T_c^{(0)}$ has no nodes. We further show that below a given $T_c^{(n)}$, the corresponding solution $\Delta(\omega_n)$ of the linearized gap equation grows in magnitude, but maintains the number of sign changes, which in this respect acts as a topological invariant. We discuss how these oscillating solutions evolve with increasing scaling dimension $\gamma$, and how they contribute to destruction of long range superconducting order.
8:36AM F48.00004: The dielectric function method for superconducting materials*
DIETRICH ELST (Presenter), SERGEI N. KLIMIN, JACQUES TEMPERE, Univ of Antwerp — The dielectric function method (DFM), which uses a non-adiabatic approach to calculate the critical temperatures for superconductivity, has been quite successful in describing superconductors at low carrier densities. This semi-phenomenological theory uses the dielectric function of the material to describe the inter-electron interaction and obtains very BCS-like equations for the superconducting gap and the critical temperature. However, DFM uses an interaction of arbitrary form, instead of a constant attraction in a Debye window as is the case for BCS. We investigate the application of DFM to the linear dispersion of single layer graphene. This is done using an interaction potential that uses the Random Phase Approximation dielectric function and thus allows for plasmonic interactions which are most relevant at low carrier doping.

8:48AM F48.00005: Odd–Parity Spin–Triplet Superconductivity in Antiferromagnetic Metals Lacking Effective Time-Reversal Symmetries*
SEUNG HUN LEE (Presenter), BOHM-JUNG YANG, Seoul Natl Univ — We propose a route to achieve odd-parity spin-triplet superconductivity in metallic collinear antiferromagnets with inversion symmetry. Owing to the existence of hidden antiunitary symmetries, which we call the effective time-reversal symmetries (eTRS), the Fermi surfaces of such systems are generally spin-degenerate. However, by introducing a local inversion symmetry breaking perturbation that also breaks the eTRS, we can lift the degeneracy to obtain spin-polarized Fermi surfaces. In the weak-coupling limit, the spin-polarized Fermi surfaces constrain the electrons to form spin-triplet Cooper pairs with odd-parity. Furthermore, we find that the odd-parity superconducting states host nontrivial band topology. We also solve the finite-size tight-binding models to show the boundary modes appear as a consequence of the bulk topology.

9:00AM F48.00006: Suppression of superfluidity by dissipation – An application to failed superconductor
KOU MISAKI (Presenter), University of Tokyo, NAOTO NAGAOSA, University of Tokyo, RIKEN CEMS — The ground states of bosons have been classified into superfluid, Mott insulator, and bose glass. Recent experiments in two-dimensional superconductors strongly suggest the existence of the fourth quantum state of Cooper pairs, i.e., bose metal or quantum metal, where the resistivity remains constant at lowest temperature. However, its theoretical understanding remains unsettled. In this talk, we show theoretically that the bosons in the dilute limit subject to dissipation can lose the superfluidity and remain metallic, utilizing the Feynman's picture of superfluidity in the first quantized formulation. This result is relevant to the quantum vortices under an external magnetic field in two-dimensional superconductors with the finite resistivity of the normal core as the source of dissipation.
9:12AM F48.00007: *SP*OT* symmetry and unconventional pairing in non-Hermitian superconductors*  
SUMANTA BANDYOPADHYAY (Presenter), Physics, NORDITA, ALEXANDER V BALATSKY, Physics, NORDITA and University of Connecticut, Storrs, CT — Novel physics with nontrivial topology and nodal structures emerge in the nonhermitian system. In this work, we investigate the role of damping as a mean to induce dynamics in the superconducting system. We find both odd (Berezinskii) and even (BCS) frequency (ω) states emerge as a result of damping in the superconductors. Odd ω pairing emerges as a result of \( SP^*OT^* \) symmetry [1]. To properly introduce Berezinskii classification in the nonhermitian superconductors, this classification should be extended to include particle-hole conjugation (\( C^* \)). \( C^*SP^*OT^* = -1 \). This symmetry constraint allows us to predict new kinds of order parameters in dynamic systems with damping. We have identified the natural occurrence of odd ω superconductivity (OFSc) in the nonhermitian systems such as odd ω s-wave spin-triplet superconducting state. We also propose experimental observables related to OFSc in such a nonhermitian system.

9:24AM F48.00008: Spontaneous Time-Reversal Symmetry Breaking in unconventional Superconductors  
MENG ZENG (Presenter), LUN-HUI HU, CONJUN WU, University of California, San Diego — Time-reversal symmetry plays a crucial role in the study of unconventional superconductivity in strongly correlated systems. When two superconducting order parameters with different pairing symmetries compete, time-reversal symmetry can be spontaneously broken due to a 2\(^{nd}\) order Josephson coupling between the competing order parameters. In this work, we show that time-reversal symmetry breaking transition can occur due to superconducting phase fluctuations before the onset of superconductivity. To illustrate this phenomenon, we employ the Ginzburg-Landau theory, and use an effective two-component XY-model to perform a renormalization group analysis to study superconducting phase fluctuations. In the time-reversal symmetry breaking normal state, neither of the pairing orders develops phase coherence, but their relative phase is pinned at ±π/2.
9:36AM F48.00009: Electromagnetic response of superconductors in the presence of multiple collective modes  RUFUS BOYACK (Presenter), University of Alberta, PEDRO LOPES, University of British Columbia — Collective-mode fluctuations play an essential role in ensuring the electromagnetic response of superfluids is gauge invariant. The contribution of these fluctuations, however, is known to drop out from the Meissner response of uniform superfluids. The same phenomenon is not so established in the context of non-uniform superfluids. To clarify this issue, we revisit how collective modes appear in the Meissner effect. We find that their contributions vanish both in uniform and non-uniform systems, unless an external length scale is present -- as in Fulde-Ferrell or finite sized superfluids. As examples, we consider s- and p-wave superconductors. To facilitate this analysis, we formulate a path-integral matrix methodology for computing the response of fermionic fluids in the presence of multiple collective modes. Closed-form expressions are provided, incorporating effects from phase and amplitude of the superconducting order parameter and electronic density fluctuations. All microscopic symmetries and invariances are manifestly satisfied in this approach, and it can be straightforwardly extended to other scenarios.

9:48AM F48.00010: Calculating the Superconducting Superheating Field within Eilenberger Theory*  ALDEN Pack (Presenter), MARK TRANSTRUM, Brigham Young Univ - Provo — For Type II superconductors in an applied magnetic field, the superconducting Meissner state can persist metastably up to a theoretical maximum, "superheating field", Hsh. Superconducting Resonance Frequency (SRF) cavities are a critical component of particle accelerators for which Hsh represents a fundamental limit to performance. As the accelerator community explores materials for next-generation cavities, such as Nb3Sn, better estimates of Hsh are needed for candidate materials. Previous calculations have used Ginzburg-Landau theory (valid near Tc), however SRF cavities often operate well below the critical temperature. Extensions to Eilenberger theory (valid at all temperatures) in the high-kappa and dirty limits have also been done. Here, we discuss the calculation of Hsh in Eilenberger theory in the clean limit. In addition to an accurate temperature dependence, the clean limit of the Eilenberger theory includes material-specific parameters for the density of states at the Fermi surface. I discuss implications for SRF cavity development.

*This work was supported by the US National Science Foundation under Award OIA-1549132, the Center for Bright Beams.
10:00AM F48.00011: Enhanced Superconductivity in Quasi-periodic Crystals* ZHIJIE FAN (Presenter), GIA-WEI CHERN, Physics, University of Virginia, SHIZENG LIN, Theoretical Division, Los Alamos National Lab — It is ubiquitous that superconductivity emerges in materials with incommensurate structure. Here we study superconductivity in a family of one-dimensional incommensurate system with s-wave pairing interaction. The incommensurate potential changes the characteristics of the electronic wave function either to extended, critical or localized states. Through standard Bogoliubov-de Gennes calculations and analytical analysis utilizing Anderson's idea of pairing the time-reversed exact eigenstates, we find that superconductivity is enhanced when the electronic wave functions are critical. The superconducting transition temperature obeys an unconventional power law relation with respect to the pairing interaction. Consequently, there exists a superconducting dome around the localization transition when the amplitude of the incommensurate potential is tuned, or near the mobility edge when the chemical potential is varied. Our results suggest a way to enhance superconducting transition temperature by introducing an incommensurate potential.

10:12AM F48.00012: Dynamic Pair-Breaking Current in Superconductors* AHMAD SHEIKHZADA (Presenter), ALEXANDER V GUREVICH, Physics, Old Dominion University — We calculated a dynamic pair-breaking current density $J_d$ and a critical condensate velocity $v_d$ in a thin film superconducting strip or a filament carrying a large-amplitude ac current $J(t) = J_0 \sin \omega t$. Here $J_d(T, \omega)$ and $v_d(T, \omega)$ in a dirty superconductor at $T \approx T_c$ were computed by numerical simulations of the time-dependent Ginzburg-Landau (TDGL) equations, as well as the full time-dependent Usadel and kinetic equations that take into account both a nonequilibrium distribution function of quasiparticles and nonlinear current pairbreaking effects. It is shown that superconductivity is destroyed at $J_0 > J_d$, where the dynamic pairbreaking current density $J_d(T, \omega)$ approaches $\sqrt{2} J_{GL}(T)$ at $\omega \tau > 1$. Here $J_{GL}(T)$ is the GL dc depairing current density and $\tau(T)$ is the energy relaxation time of quasiparticles on phonons. Nonlinear electromagnetic response of a nonequilibrium superconductor and intermodulation at $J < J_d$ were also calculated.

*This work was supported by DOE under grant No. DE-SC0010081.
10:24AM F48.00013: Collective modes in Bogoliubov Fermi surfaces without gapless Goldstone modes*  
JAY SAU (Presenter), BRIAN SWINGLE, Physics, University of Maryland, College Park — We study collective modes of a finite temperature Bogoliubov Fermi surface with no symmetries. The Bogoliubov Fermi surface is assumed to form in a superconductor with Coulomb interactions, so that the plasmon is gapped and there is no low lying Goldstone mode in the system. Despite this we find the existence of a gapless second sound, which is a collective mode of energy and momentum fluctuations that is not related to any Goldstone mode. This is different from previously discussed second sound modes in either superfluids or crystals, where the second sound co-exists with and is related to a spontaneously broken symmetry with a gapless Goldstone mode. Thus these modes are an example of collective modes that are solely related to conservation of energy/momentum.

10:36AM F48.00014: Floquet theory of periodically-driven superconductors*  
DANILO LIARTE (Presenter), JAMES MANISCALCO, MICHELLE KELLEY, NATHAN SITARAMAN, TOMAS ARIAS, MATTHIAS ULF LIEPE, JAMES PATARASP SETHNA, Cornell University — We use Floquet theory to describe dynamics and losses of superconductors under extremely high fields and frequencies. Periodically-driven superconductors at high fields provides an unexplored theoretical territory relevant in modern applications (lower cryogenic costs for particle accelerators), allowing for experimental validation using Superconducting-Radio-Frequency (SRF) cavities. We use the Floquet formalism to solve the Cooper problem in the limit of strong AC fields (in which linear-response analysis does not apply). We also discuss preliminary results combining BCS and Floquet theories to develop an experimentally-verifiable new approach for periodically-driven superconductors that provides explanation and control of dissipation, with relevance for condensed matter physics and the ‘positive Q slope’ of SRF cavities.

F48.00015: Effect of Defects in Superconducting Phase of Twisted Bilayer Graphene  
HUI YANG (Presenter), ZHI-QIANG GAO, FA WANG, Peking Univ — In this work we study the effect of impurity in the superconducting phases of the twisted bilayer graphene (TBG) by analysing bound states induced by the impurity. As a comparison with the superconducting phase, we first consider the impurity effect in the TBG without superconductivity in the scheme of a low energy effective theory. For superconductivity, our basis is a four-band model2 with different superconducting pairing symmetries. Then we construct the effective impurity Hamiltonian and compute the local density of state (DOS). We find that for different kind of pairing symmetries the numbers of bound states are different. These results can in principle be detected in scanning tunnelling microscopy (STM) experiments, and therefore the pairing symmetry may be determined. Finally we consider the multi-impurity effect and compute phase diagrams in terms of effective gap and the strength and density of impurities. We find that in (p + ip)-wave and (d + id)-wave phases superconductivity will be destroyed by impurities with strong strength or concentration.
8:00AM F49.00001: THz emission characteristics from mesa arrays of Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ single crystals  
TAKANARI KASHIWAGI (Presenter), TAKAYUKI IMAI, SYUNGO NAKAGAWA, GENKI KUWANO, YUKINO ONO, TOMOYUKI SHIZU, YOUTA KANEKO, SHINJI KUSUNOSE, MAYU NAKAYAMA, JEONGHYUK KIM, MANABU TSUJIMOTO, University of Tsukuba, TAKASHI YAMAMOTO, QuTech Delft University of Technology, HIDETOSHI MINAMI, University of Tsukuba, TAKASHI MOCHIKU, National Institute for Materials Science, HIRONORI NAKAO, Institute of Materials Structure Science, High Energy Accelerator Research Organization, HIROSHI EISAKI, SHIGEYUKI ISHIDA, YASUNORI MAWATARI, National Institute of Advanced Industrial Science and Technology, YUKIO HASEGAWA, The University of Tokyo, RICHARD KLEMM, University of Central Florida, KAZUO KADOWAKI, University of Tsukuba — 

To develop the high power terahertz emission from Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ (Bi2212) high-$T_c$ superconducting THz emitters (Bi2212-THz emitters), it is very important to manage self-heating of these devices. We have developed stand-alone mesa structures (SAMs) of Bi2212 single crystals sandwiched by good thermal conducting sapphire substrates to reduce self-heating effects. These thermal managed devices enable us to extend the range of the radiation frequencies up to around 2.4 THz. For applications of THz emitters, 1 mW level of output power and 1 kHz level of radiation linewidth are required. In order to obtain such high performance characteristics from our Bi2212-THz emitters, we have studied not only about thicker SAMs but also arrays of SAMs. The SAMs up to around 8 μm thickness with keeping good shape of mesa structures can be obtained by a wet etching method so far. We made arrays of those SAMs by using the thermal managed device structures. At this moment, we observed about 10 μW level of output power from two arrays of SAMs with the dimensions of 69 × 190 × 4.2~4.4 μm$^3$. The details of the current situation of our Bi2212-THz emitters will be discussed.
8:12AM F49.00002: Mesa sidewall effect on coherent terahertz radiation from Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ intrinsic Josephson junctions* GENKI KUWANO (Presenter), YOUTA KANEKO, KANAE NAGAYAMA, TAKAYUKI IMAI, YUKINO ONO, SHINJI KUSUNOSE, TAKANARI KASHIWAGI, HIDETOSHI MINAMI, KAZUO KADOWAKI, MANABU TSUJIMOTO, University of Tsukuba — Coherent terahertz sources based on the stack of Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ intrinsic Josephson junctions (IJJs) have been attracted in the academic and industrial fields. See Ref. [U. Welp et al., Nat. Photonics, vol. 7, p. 702 (2013)] for recent review. In this study, we demonstrate that tapered sidewalls produce a difference in the junction voltages along the stack and thus synchronization among the IJJs fails to occur with distributed oscillation frequencies. Also, our systematic experiment using shielding metal masks reveals that only the ac Josephson current flowing along the sidewall can generate the terahertz waves outside of the mesa. These results suggest that the condition of the sidewall is essentially important to control the radiation characteristics. In this talk, we will present the details of the fabrication process and experimental results and will discuss the role of the mesa sidewalls on the coherent radiation.

8:24AM F49.00003: Electromagnetic field analysis of coherent terahertz radiation emitted from stacks of intrinsic Josephson junctions of BSCCO with microstrip antennas* MANABU TSUJIMOTO (Presenter), YOUTA KANEKO, GENKI KUWANO, KANAE NAGAYAMA, SHINJI KUSUNOSE, TAKAYUKI IMAI, YUKINO ONO, TAKANARI KASHIWAGI, HIDETOSHI MINAMI, KAZUO KADOWAKI, University of Tsukuba — The observation of coherent terahertz radiation from a stack of intrinsic Josephson junctions (IJJs) in Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ (BSCCO) highlighted the potential of using high-$T_c$ superconductors as compact and convenient terahertz sources. So far, synchronized IJJ mesa arrays were demonstrated to produce the output power up to 0.6 mW [Benseman et al., APL (2013)], which is presently the highest recorded level among all available terahertz sources. To increase the output power further up to milliwatt-level, we need to mitigate impedance mismatch at the boundary between an emitting IJJ stack and a dielectric medium or free space. In this study, we implement the electromagnetic field analysis of the radiation emitted from IJJs stacks with microstrip antennas, which are designed for highly efficient radiation. We established a microfabrication process based on the lift-off technique to pattern the microstrip antenna. In this talk, we will discuss the characteristic radiation behavior associated with the bath and local temperatures and variation in polarization characteristics depending on the bias point.

*This work was supported by KAKENHI (Grants No. 19H02540) and the Program to Disseminate the Tenure Tracking System at the University of Tsukuba.
8:36AM F49.00004: THz emission peak at low voltage bias from stacked intrinsic Josephson junction Bi$_2$Sr$_2$CaCu$_2$O$_8$ terahertz sources*  
KAREN J KIHLSTROM (Presenter), TIMOTHY BENSEMAN, Physics, Queens College CUNY, ALEXEI KOSHELEV, ULRICH WELP, WAI-KWONG KWOK, Materials Science Division, Argonne National Laboratory, KAZUO KADOWAKI, Institute for Materials Science, University of Tsukuba — The extremely anisotropic high-temperature superconductor Bi$_2$Sr$_2$CaCu$_2$O$_8$ contains stacked 'intrinsic' Josephson junctions with a large superconducting gap energy. Mesa-shaped devices constructed from this material therefore show promise as a source of coherent, continuous-wave radiation in the 'terahertz gap' range. THz emission from these devices has previously been typically observed at frequencies between around 0.4 THz – 2 THz, corresponding to Josephson voltages of between 0.8 mV and 4 mV per intrinsic junction. However, we have recently observed a new type of emission which occurs at bias currents below the retrapping current of the stacked Josephson junctions. This unusual THz emission state is highly reproducible, is metastable over a timescale of hours, and shows systematic temperature dependence. The maximum emitted THz power that can be generated from this mode is comparable to that generated by the more well-established and better-understood THz emission modes in Bi$_2$Sr$_2$CaCu$_2$O$_8$ mesa sources. We will discuss possible mechanisms for the unusual emission mode, together with future directions of related research.

8:48AM F49.00005: Stacked intrinsic Josephson junction Bi$_2$Sr$_2$CaCu$_2$O$_8$ terahertz sources: Design issues for achieving high power output close to $T_c$*  
TIMOTHY BENSEMAN (Presenter), KAREN J KIHLSTROM, Physics, Queens College CUNY, ALEXEI KOSHELEV, ULRICH WELP, WAI-KWONG KWOK, Materials Science Division, Argonne National Laboratory, KAZUO KADOWAKI, Institute for Materials Science, University of Tsukuba — The high-temperature superconductor Bi$_2$Sr$_2$CaCu$_2$O$_8$ contains stacked 'intrinsic' Josephson junctions, with unrivalled packing density and a high superconducting gap energy. Cuboid 'mesa' devices constructed from this material are consequently a promising technology for coherent, continuous-wave radiation in the 'terahertz gap' range, spanning from approximately 0.3 – 1.5 THz. A key issue for practical applications of such devices is their cryocooling requirements, and it is therefore highly desirable to optimize their performance at temperatures that can be achieved by nitrogen cryogenics. Here we report generation of 0.15 milliwatts of coherent emission power at 0.5 THz, at a bath temperature of 77 Kelvin. This was achieved by exciting the (3, 0) cavity mode of a stack containing 580 junctions, and $T_c$ of 86.5 Kelvin. In order to minimize self-heating, the THz source was mounted on a copper substrate using PbSn solder. We will discuss the choice of mesa dimensions and cavity mode, and implications for the design of devices which are intended to operate close to the material's superconducting critical temperature.

9:00AM F49.00006: Demonstrating phase control in spin-triplet ferromagnetic Josephson junctions* VICTOR AGUILAR (Presenter), REZA LOLOEE, WILLIAM P PRATT, NORMAN BIRGE, Physics and Astronomy, Michigan State University — Ferromagnetic Josephson junctions show promise for application in energy efficient cryogenic memory [1]. Both spin-singlet and spin-triplet supercurrents are being studied by our group for this purpose. Engineering adjacent F layers in a three-layer system to have perpendicular magnetizations allows singlet pairs to convert to spin-aligned triplet pairs. Recent work in our group exploited a synthetic antiferromagnet (SAF) with perpendicular magnetic anisotropy (PMA) as the central layer. These junctions have been shown to exhibit phase control [2] but have a low critical current when compared to singlet junctions. We have shown that removing the SAF while maintaining the PMA increases the critical current by a significant amount. We demonstrate phase-control by fabricating two of these junctions in a SQUID loop, and measuring SQUID oscillations for combinations of the parallel and anti-parallel magnetic states in the two junctions.

*This work was supported by Northrop Grumman Corporation.

9:12AM F49.00007: Ferromagnetic Josephson junctions with perpendicular magnetic anisotropy* NATHAN SATCHELL (Presenter), PHILIPPA SHEPLEY, GAVIN BURNELL, Univ of Leeds — Ferromagnetic Josephson junctions are a strong candidate to become a dissipationless cryogenic memory alternative to dissipative CMOS technologies. In order to build such a memory, the ferromagnetic Josephson junctions must be optimised for both the switching of the ferromagnetic layer and the critical current of the junction. The critical current of the junction decays exponentially with the ferromagnet thickness, making a thin ferromagnet preferable, however typically for in-plane ferromagnets the switching properties worsen as the ferromagnet is thinned. In addition, stray fields from an in-plane ferromagnet add a vector potential in the Josephson junction. To solve these issues, here we explore the use of ferromagnets with perpendicular magnetic anisotropy. We find that, unlike for in-plane ferromagnets, the switching properties of Co in a Nb-Pt-Co($d_{Co}$)-Pt-Nb wedge are optimised for ultra-thin ($\leq$0.6 nm) films. We will also report our progress characterising Josephson junctions with perpendicular Co and CoB ferromagnetic layers.

9:24AM F49.00008: High Field Superconductivity and Magnetic Moment Enhancement in Proximity Exchange Coupled GdN/NbN Nano-bridges*  MIRKO ROCCI (Presenter), DHAVALA SURI, Massachusetts Institute of Technology MIT, NORBERT MARCEL NEMES, Fisica de los Materiales, Universidad Complutense de Madrid and ICMM-CSIC, JOSE LUIZ MARTINEZ, MAR GARCIA-HERNANDEZ, Instituto de Ciencia de Materiales de Madrid - CSIC, JAGADEESH MOODERA, Massachusetts Institute of Technology MIT — Proximity effects in ferromagnetic insulator/superconductor (FI/SC) interface have been highly intriguing in terms of fundamental exploration as well as technological relevance [1,2]. We perform detailed investigations on GdN (FI) and NbN (SC) interface via magneto-transport properties of GdN/NbN-based nano-bridges and thin film heterostructures. We observe a clear enhancement of magnetic moment and a drastic increase of coercive field, below the superconducting transition temperature of NbN, which may be attributed to exchange coupled effect between GdN and NbN at the interface. Most interestingly, our nano-bridges exhibit a large magnetic field dependent superconductivity enhancement for fields > 5T similar to the Jaccarino effect [3]. The observed effect is temperature dependent implying a free energy dependence at the interface. Finally, we also discuss the exchange coupled interface effects and their implications in GdN/NbN system.

9:36AM F49.00009: Optimizing supercurrent transmission and magnetic behavior in ferromagnetic Josephson junctions*  SWAPNA SINDHU MISHRA (Presenter), ROBERT M KLAES, REZA LOLOEE, NORMAN BIRGE, Physics and Astronomy, Michigan State University — Josephson junctions with ferromagnetic layers where the ground-state phase difference can be reliably controlled are a potential candidate for applications in cryogenic memory devices, which can greatly reduce the ever-growing energy requirements for large-scale computing. Phase control has been successfully demonstrated with junctions containing a Ni fixed layer and a NiFe free layer[1,2]. However, there are still a number of improvements that can be made to increase the efficiency and reliability of these junctions. We present work on trying to improve the efficiency by using thin layers of Ni “dusting” around the NiFe free layer to further increase the transmission of supercurrent through these junctions. We also present work on improving the switching reliability by replacing the fixed Ni layer with unbalanced Ni SAFs which may have more desirable magnetic properties.

*This research is based upon work supported by Northrop Grumman Corporation.
Three-dimensional (3D) topological semimetals possess unconventional surface and edge states, which play central roles in exotic topological phases. WTe$_2$, as a type-II Weyl semimetal, has 2D Fermi arcs on the (001) surface in the bulk and 1D helical edge states in its monolayer. However, in the intermediate regime between the bulk and monolayer, the edge states have not been resolved owing to its closed band gap which makes the bulk states dominant. Here, we report the signatures of the edge states by superconducting quantum interference measurements in multilayer WTe$_2$ Josephson junctions and we directly map the localized supercurrent. In thick WTe$_2$ (~60 nm), the supercurrent is uniformly distributed on the (001) surface. In thin WTe$_2$ (10 nm), however, the supercurrent becomes confined to the 1D edge modes and its width reaches up to 1.4 μm. Furthermore, an asymmetric Josephson effect, predicted as a unique characteristic of inversion-symmetry-breaking topological systems, is observed in thin WTe$_2$ whereas it is absent in the thick one. The ability to combine superconductivity with these edge states establishes WTe$_2$ as a promising topological system with exotic quantum phases and a rich physics of extra dimensionality and tunability.

An Alternate Scheme to Mode-Lock Quantum Phase Slips. BASTIEN DASSONNEVILLE (Presenter), JOSE AUMENTADO, National Institute of Standards and Technology Boulder — It has been proposed that locking the voltage oscillations of a Quantum Phase Slip Junction (QPSJ) to a microwave source could achieve the transfer of an integer number of elementary charges per microwave cycle. Such a synchronized transfer of charge would correspond to current steps in the current-voltage characteristic of the QPSJ, which could be used to realize a current standard. These proposals focus on realizing a circuit dual to the Josephson voltage standard and therefore require placing a QPSJ close to a resistor whose value is larger than the superconducting quantum of resistance. The observation of current steps for such a circuit is however extremely challenging experimentally, mostly due to the large Joule heating occurring in the resistor. To address this problem, we consider alternative designs that relax the constraint on the resistance and instead rely on the feedback provided by a high-impedance resonator. Through numerical simulations, we demonstrate that mode-locking indeed occurs in such systems and that synchronized charge transfer can be achieved in a resonant environment, without the need for a large resistor. Such a circuit may offer an alternative path toward the realization of a current standard.
10:12AM F49.00012: Exploring parity transitions of Majorana bound states in S-TI-S lateral Josephson junctions

GUANG YUE (Presenter), Department of Physics, University of Illinois at Urbana-Champaign, XIONG YAO, DEEPTI JAIN, JISOO MOON, SEONGSHIK OH, Department of Physics & Astronomy, Rutgers, The State University of New Jersey, ALEXEY BEZRYADIN, DALE J VAN HARLINGEN, Department of Physics, University of Illinois at Urbana-Champaign — It is predicted that S-TI-S lateral Josephson junctions, fabricated by depositing electrodes of a conventional superconductor (S) on the surface of a topological insulator (TI), exhibit Majorana bound states (MBS) at locations in the junction where the phase difference is an odd-multiple of π, i.e. at the cores of the Josephson vortices. There is evidence for this from the lifting of odd nodes in the critical current diffraction patterns and the observation of supercurrent features at magnetic field where the MBS enter the junction. In this talk, we report progress on experiments designed to probe the parity states of MBS pairs and the transitions between them via measurements of the critical current distribution and supercurrent fluctuations. These experiments give information about parity lifetimes and open the door to understand the factors that limit them.

10:24AM F49.00013: Topological Josephson Junctions in Corbino geometry

ANANTHESH SUNDARESH (Presenter), TYLER LINDEMAN, Department of Physics and Astronomy, PURDUE UNIVERSITY, GEOFF C GARDNER, SERGEI GRONIN, Microsoft Quantum Purdue, MICHAEL MANFRA, LEONID ROKHINSON, Department of Physics and Astronomy, PURDUE UNIVERSITY — One-dimensional hybrid semiconductor/superconductor wires and, more recently, long Josephson junctions are the most versatile synthetic topological superconductors where non-abelian excitations can be realized and thoroughly investigated. In both realizations quasiparticle states appear at the physical boundaries, either at the ends of the nanowires or at the edges of the Josephson junction. Signatures of these states have been observed, studied and investigated by several groups with respect to various parameters such as magnetic field, chemical potential and the superconducting phase difference. In this work we report experimental investigation of Josephson junctions in the Corbino geometry fabricated from InAs/Al heterostructures. These devices are in a long junction regime with periodic boundary conditions. Transport studies of these junctions in a normal regime (zero in-plane magnetic field) and in the regime where some regions of the junction are in a topologically non-trivial regime (non-zero in-plane magnetic field) will be presented.

*The project was supported by DOE Basic Energy Sciences award DE-SC0008630.
10:36AM F49.00014: Engineering the spin-orbit interaction in InAs-based quantum wells for superconductor-semiconductor hybrid structures* MICHAEL PRAGER (Presenter), MARTIN SPECKNER, JAY SCHMIDT, DIETER SCHUH, DOMINIQUE BOUGEARD, University of Regensburg — Superconductor (SC)-semiconductor hybrid structures open an access to exotic superconductivity, enabling the creation of Majorana zero modes in appropriate devices. The strength of the spin-orbit interaction (SOI) in the structure represents an important parameter, driving for example the size of the energy gap induced into the SC. InAs-based epitaxial hybrid heterostructures have emerged as a promising candidate for such systems, exploiting the rather large intrinsic SOI of InAs and the epitaxial matching with SCs such as aluminum (Al). In this work, we present a systematic study of two-dimensional electron gases (2DEGs) realized in strongly asymmetric InAs/InGaAs/InAlAs quantum well layouts. We show that the SOI in such 2DEGs is substantially enhanced by engineering the asymmetry through the position of the InAs inset and the doping layer. We characterize the strength of the SOI in the 2DEGs by analyzing SOI-induced features in low temperature magneto transport, such as zero-field spin splitting-induced beating patterns and weak antilocalization, as well as by exploring the energy gap induced into epitaxial superconducting Al.

*We acknowledge funding by the Deutsche Forschungsgemeinschaft via SFB 1277 project A01

10:48AM F49.00015: Anomalously large second Josephson harmonic in quantum well-based junctions AZARIN ZARASSI (Presenter), Univ of Pittsburgh, LUCAS JARJAT, Ecole Normale Superieure, VINCEN VAN DE SANDE, TU Eindhoven, MIHIR PENDHARKAR, JOON SUE LEE, ANTHONY P MCFADDEN, SEAN HARRINGTON, Univ of California, Santa Barbara, SASA GAZIBEGOVIC, GHADA BADAWY, ROY OP HET VELD, TU Eindhoven, MOIRA HOCEVAR, Neel Institute, CNRS, SUSHENG TAN, Univ of Pittsburgh, ERIK BAKKERS, TU Eindhoven, CHRIS J PALMSTROM, Univ of California, Santa Barbara, SERGEY M FROLOV, Univ of Pittsburgh — The current-phase relation (CPR) of a Josephson junction (JJ) contains information about the microscopic mechanisms behind supercurrent. The sinusoidal CPR can successfully describe most JJs made with different materials and synthesis technologies. However, CPR can also deviate from simply sinusoidal form, in particular it can feature higher order sinusoidal terms. We investigate InAs quantum well JJs with epitaxial Al contacts. The distance between Al electrodes is of order 100 nm shorter than the mean free path in the quantum well. We perform diffraction pattern measurements, SQUID measurements and Shapiro step measurements all pointing at a strong intrinsic second order harmonic.
8:00AM F50.00001: Two-dimensional non-Fermi liquids with quenched disorder* PAVEL NOSOV (Presenter), SRINIVAS RAGHU, Stanford Univ — Despite significant theoretical progress, the effect of quenched disorder on non-Fermi liquids with a finite density of fermions interacting with soft order parameter fluctuations near a quantum critical point remains poorly understood. We study the interplay of disorder and interactions in the exactly solvable "matrix large N" non-Fermi liquid model in two spatial dimensions. We investigate the stability of the corresponding strongly interacting fixed point and show that diffusive effects drastically modify the properties of the critical regime and associated critical exponents.

8:12AM F50.00002: Pairing Instability on a Luttinger Surface: A Non-Fermi Liquid to Superconductor Transition and its SYK Dual CHANDAN SETTY (Presenter), University of Florida — Instabilities of the Fermi Surface -- contours of poles of the single particle Green function -- such as superconductivity, density waves (CDW, SDW, PDW..) etc are now a commonplace in modern condensed matter physics. In this talk, I will discuss the problem of superconducting instability on a model Luttinger surface, or contours of zeros of the many-body Green function. Unlike a Fermi surface, in the presence of an attractive potential, the model exhibits -- in the strong coupling limit -- a quantum phase transition into a superconducting state. The spectral density of pair fluctuations in the "normal" state of the superconductor has a power-law type van-Hove singularity signalling non-Fermi liquid transport. Crucially, the fluctuation free energy in the non-Fermi liquid resembles well-studied models with gravity duals such as SYK. These results shed light on the role played by order-parameter fluctuations in providing the key missing link between Mottness and strongly coupled toy-models exhibiting gravity duals.

8:24AM F50.00003: Low-energy level spacing and entropy change across SYK non-Fermi liquid to a Fermi Liquid transition for finite-N* SUMILAN BANERJEE (Presenter), SURAJIT BERA, Indian Institute of Science, ARJIT HALDAR, Physics, University of Toronto — We study a quantum phase transition (QPT) between a Sachdev-Ye-Kitaev (SYK) non-Fermi liquid (NFL) and a Fermi liquid in a solvable large-N model where the zero-temperature residual entropy of the NFL vanishes continuously at the QPT in the large-N limit. We show via exact diagonalization that, even at finite-N, the QPT manifests itself in the system-size scaling of low-energy level spacings above the ground state. The evidence of this QPT is also directly visible in the single-particle Greens function and, indirectly, in the thermalization dynamics after a quench. Interestingly, we find that the QPT has little effect on the entanglement entropy in the ground state. We also construct the effective low-energy field theory across the QPT by considering fluctuations around the large-N limit.

8:36AM F50.00004: Phases of the t-J model with random and all-to-all hopping and exchange  
DARSHAN JOSHI (Presenter), CHENYUAN LI, SUBIR SACHDEV, Harvard University — We study a t-J model with both t and J random and all-to-all. This model has been studied earlier [1], and can be mapped to an Anderson impurity coupled to self-consistent fermionic and bosonic baths. We employ renormalization group and large M (for models with SU(M) spin symmetry) analyses, and find evidence for a critical non-Fermi liquid phase at zero temperature and small doping. The critical spin correlations are similar to those in a random magnet [2]. A disordered Fermi liquid phase is expected at large doping. We note connections to the physics of the underdoped cuprates.

8:48AM F50.00005: Fermi-surface Reconstruction in the Repulsive Fermi-Hubbard Model  
IAN OSBORNE (Presenter), NANDINI TRIVEDI, Ohio State Univ Columbus, THEREZA PAIVA, Univ Federale do Rio de Janeiro — One of the fundamental questions about the high temperature cuprate superconductors is the size of the Fermi surface underlying the superconducting state. By analyzing the single particle spectral function for the Fermi Hubbard model as a function of repulsion $U$ and chemical potential $\mu$, we find that the Fermi surface reconstructs from a large Fermi surface enclosing $(1+p)$ holes, matching the Luttinger volume as expected in a Fermi liquid, to a small Fermi surface enclosing only $p$ holes, thereby transitioning into a non-Fermi liquid FL* phase, as the Mott insulator at half filling is approached. We obtain the Fermi surface contour by combining results of: (a) momentum distribution function $n_k = 1/2$, (b) spectral weight $A_k(\omega = 0)$, and (c) retarded Green's function, $G_k^{\text{ret}}(E) = 0$, calculated using determinantal quantum Monte Carlo and analytic continuation methods. We compare our numerical results with experiments on Hall measurements.

9:00AM F50.00006: Probing out-of-time-order correlators using thermofield double states  
ETIENNE LANTAGNE-HURTUBISE (Presenter), STEPHAN PLUGGE, OGUZHAN CAN, MARCEL FRANZ, University of British Columbia — We propose a new family of protocols for measurements of out-of-time order correlators (OTOCs) that do not require backward time evolution. Instead, they rely on ordinary time-ordered measurements performed in the thermofield double (TFD) state, an entangled state formed between two identical copies of a quantum system. In particular, we show how Lyapunov exponents of quantum chaotic systems can be extracted from various time-ordered correlators (including equilibrium Green's functions) in the TFD state. Importantly, TFD states can be realized as ground states of simple Hamiltonians coupling two identical systems, which underlies their usefulness for experimental explorations of quantum chaos. We numerically test our protocols on two coupled SYK models, recently proposed to be dual to an eternal traversable wormhole, and discuss possible realizations of this setup.
Non-Laudau Quantum Phase Transitions and Nearly-Marginal Fermi Liquid

YICHEN XU (Presenter), University of California, Santa Barbara, HAO GENG, Department of Physics, University of Washington, XIAOCHUAN WU, University of California, Santa Barbara, CHAO-MING JIAN, Station Q, Microsoft, CENKE XU, University of California, Santa Barbara — Marginal fermi liquid and quantum critical points (QCP) with strong fractionalization are two exceptional phenomena beyond the classic condensed matter doctrines, which could occur in strongly interacting quantum many-body systems. This work demonstrates that these two phenomena may be tightly connected. To elaborate this connection, we propose a physical mechanism for "nearly-marginal Fermi liquid", namely the fermion self-energy scales as \( \Sigma_f(i\omega) \sim |\omega|^{\alpha} \) with \( \alpha \) close to 1 in a considerable energy window. The nearly-marginal fermi liquid is obtained by coupling an electron fermi surface to unconventional QCPs that are beyond the Landau's paradigm. This mechanism relies on the observation that the anomalous dimension \( \eta \) of the order parameter of these unconventional QCPs can be close to 1, which is significantly larger than conventional Laudau phase transitions. The fact that \( \eta \sim 1 \) justifies a controlled perturbative renormalization group expansion proposed previously. Candidate QCPs that meet this desired condition are proposed.

Planckian superconductor

YEVHENIIA CHEIPESH, Lorentz Institute for theoretical physics, Leiden University, ANDREI PAVLOV, The Abdus Salam International Centre for Theoretical Physics (ICTP), VINCENZO SCOPELLITI, Lorentz Institute for theoretical physics, Leiden University, JAKUB TWORZYDLO, Institute of Theoretical Physics, University of Warsaw, NIKOLAY GNEZDILOV (Presenter), Physics Department, Yale University — The Planckian relaxation rate \( h/t_p=2\pi k_B T \) sets a characteristic time scale for both equilibration of quantum critical systems and maximal quantum chaos. We show that at the critical coupling between a superconducting dot and the complex Sachdev-Ye-Kitaev model, known to be maximally chaotic, the pairing gap \( \Delta \) behaves as \( \eta h/t_p \) at low temperatures, where \( \eta \) is an order one constant. The lower critical temperature emerges with a further increase of the coupling strength so that the finite \( \Delta \) domain is settled between the two critical temperatures.

---

Branching time and Many-body Chaos

YINGFEI GU, Havard, ALEXEI KITAEV, Caltech, HUI ZHAI, Tsinghua University, PENGFEI ZHANG (Presenter), Caltech — Branching time is defined in terms of the retarded kernel to quantify the stringy effects in SYK-like models. In this work, after presenting a weighting trick to calculate the branching time, we prove a bound on the branching time for a large class of systems. We also derive a relation between the branching time, the Lyapunov exponent and the quasiparticle lifetime for weakly coupling models.
9:48AM F50.00010: A cascade of non-Fermi liquid crossovers from an interplay of local and bosonic quantum criticality  
ANDRES FELIPE SCHLIEF RAETHER (Presenter), Max Planck Institute for the Physics of Complex Systems, FRANCISCO MARTIN BLANCO, DEBANJAN CHOWDHURY, Department of Physics, Cornell University — We present examples of multi-orbital electronic lattice models, coupled to bosonic collective modes with modified Sachdev-Ye-Kitaev form of interactions, which become solvable when the number of orbitals and collective modes is taken to be large. At high energies, these models display non-Fermi liquid behavior with local quantum criticality and are described by a strongly coupled electron-boson fluid. As a function of decreasing energy scales, they exhibit a crossover into an incipient heavy Fermi liquid regime, where the interaction between the bosonic mode and the coherent electronic quasiparticles near the Fermi surface leads to Landau damping. When the boson gap is tuned to criticality, the feedback of the damped boson on the electrons leads to a low-temperature non-Fermi liquid with a critical Fermi surface. Our models thus describe a cascade of crossovers from a dynamical critical exponent $z=\infty$ down to $z=3$ in a controlled setting as a function of decreasing energy scales.

10:00AM F50.00011: Bose Metal as a Nematic Phase Glass  
ANTHONY HEGG (Presenter), Shanghai Jiao Tong University, WEI KU, JINNING HOU, Tsung-Dao Lee Institute — A widely accepted microscopic theory for the Bose metal has yet to emerge despite mounting experimental evidence of a metallic phase intervening between the extremes of superfluid and insulator for low-temperature bosons. The reasons for this are two-fold: metallic solutions tend to be highly unstable, and stable solutions tend to utilize the unphysical limit of arbitrarily low particle density. We present a first-of-its-kind stable microscopic theory for the Bose metal with constant particle density in the thermodynamic limit. In this theory, repulsive interactions cause spontaneous symmetry breaking in an otherwise massively degenerate single-particle ground state. The key physics behind the stability of the Bose metal lies in the structure of the phase coherence. In contrast to the typical isotropic long-range order of superfluidity, our 3D theory exhibits long-range nematic phase coherence in each 2D plane while suffering from short range decoherence between planes. The resulting current response cannot maintain phase coherence beyond a finite length scale. Our discovery of a stable low-temperature phase that exhibits metallic conductivity elevates the Bose metal to one of the fundamentally intrinsic bosonic phases of matter alongside that of the superfluid and insulator.
Exploring order-to-order transitions of Dirac fermions in the regime of strong interactions

LUKAS WEBER (Presenter), STEFAN WESSEL, RWTH - Aachen — In recent years, there has been a growing interest in direct and continuous quantum phase transitions between ordered phases that do not conform with the Landau-Ginzburg paradigm. It has since been a challenge to identify models that host such transitions.

One model of interest consists of interacting Dirac fermions coupled to a transverse-field Ising model on the honeycomb lattice. It has been suggested that there is an order-to-order transition between the competing antiferromagnetic (AFM) and Ising ordered phases of this model [1]. However, the quantum Monte Carlo simulations employed were restricted to relatively small system sizes so that finite-size effects remain an issue. In the strongly interacting regime, this system can be described by an effective quantum spin model of coupled Heisenberg and Ising spins.

Within this setting, highly efficient quantum Monte Carlo methods available for spin systems can be used to drastically improve on the precision of the original fermionic estimates. In our simulations, we resolve a narrow coexistence region between the Ising and AFM-ordered phases, in contrast to the direct single transition proposed in Ref. [1].

Scale Invariant Entanglement Negativity at the Many-Body Localization Transition

JOHNNIE GRAY, Imperial College London, ABOLFAZL BAYAT, University of Electronic Science and Technology of China, ARIJEET PAL (Presenter), SOUGATO BOSE, Univ Coll London — The exact nature of the many-body localization transition remains an open question. An aspect which has been posited in various studies is the emergence of scale invariance around this point, however the direct observation of this phenomenon is still absent. Here we achieve this by studying the logarithmic negativity and mutual information between disjoint blocks of varying size across the many-body localization transition. The two length scales, block sizes and the distance between them, provide a clear quantitative probe of scale invariance across different length scales. We find that at the transition point, the logarithmic negativity obeys a scale invariant exponential decay with respect to the ratio of block separation to size, whereas the mutual information obeys a polynomial decay. The observed scale invariance of the quantum correlations in a microscopic model opens the direction to probe the fractal structure in critical eigenstates using tensor network techniques and provide constraints on the theory of the many-body localization transition.
10:36AM F50.00014: g=2 nonlinear sigma model revisited  CHAO-JUNG LEE (Presenter), Caltech, MICHAEL C MULLIGAN, Physics and Astronomy, University of California - Riverside — We consider the transport properties of free fermions with gyromagnetic ratio g=2 in the presence of quenched disorder. This system has been shown to be closely related to the mean-field limit of various composite fermion theories [1,2,3]. We derive the nonlinear sigma model that describes the electrical and spin conductivities via the supersymmetric approach [4], and discuss its physical implications for various quantum phase transitions.

Session F51 DCMP: Magnetism and Magnetic Phenomena in 2D Materials Mile High Ballroom 1D - Te-Yu Chien, University of Wyoming

8:00AM F51.00001: Unconventional anomalous Hall effect in Fe₃GeTe₂ and Fe₅GeTe₂*  JUAN MACY (Presenter), YU-CHE CHIU, Physics, Florida State University, ASHLEY WEILAND, GREGORY MCCANDLESS, JULIA CHAN, Chemistry & Biochemistry, University of Texas at Dallas, LUIS BALICAS, National High Magnetic Field Laboratory — Fe₃GeTe₂ and Fe₅GeTe₂ are layered and exfoliable compounds that display what seemingly are ferromagnetic (FM) transitions below T_c ~ 220 and 280 K, respectively. At low fields, both compounds display an anomalous Hall effect (AHE) that scales with the magnetization. For FM materials, this AHE has been described using Berry phase concepts or argued to be topological in nature [1, 2], with a specific scenario [3] proposed for Fe₃GeTe₂. However, measurements of the magnetic torque reveal a second metamagnetic transition observed in both compounds in fields exceeding 10 T. These indicate that neither compound can be considered as a simple collinear ferromagnet [4], in agreement with Ref. [5], and hence that their AHE is not intrinsic. For both compounds, the AHE remains oblivious with respect to the occurrence of these metamagnetic transitions, indicating that an unconventional scenario is required to explain it.

**Gate-tunable magnetism in vanadium-doped tungsten diselenide monolayer**

DINH LOC DUONG (Presenter), Department of Energy Science (DOES), Sungkyunkwan University (SKKU), Korea, SEOK JOON YUN, YOUNG-HEE LEE, Center for Integrated Nanostructure Physics (CINAP), Institute for Basic Science (IBS), Korea — Controlling magnetic properties by tuning carrier concentration is a key feature of diluted ferromagnetic semiconductors, giving possibilities for multifunctional spintronic devices. Here, we investigate the gate-modulation of the long-range magnetic order in p-type vanadium-doped WSe$_2$ monolayer by both experiments and simulations. We found that a transition from the long-range ferromagnetic order to the short-range antiferromagnetic order can be tuned by injecting electrons to compensate for the p-doping effect of vanadium by density functional calculations. The magnetic domains observed by magnetic force microscopy are strongly modulated by applying gate biases. Our findings propose the strong coupling between charge and spin order in vanadium-doped WSe$_2$, opening possibilities for using two-dimensional semiconductors for spintronic devices.

**Proximity effect between graphene and 2D anti-ferromagnetic insulator α-RuCl$_3$**

EDWARD SEIFERT (Presenter), DEVASHISH P GOPALAN, Carnegie Mellon Univ, ZAIYAO FEI, XIAODONG XU, Physics, University of Washington, DAVID MANDRUS, Oak Ridge National Laboratory, BENJAMIN HUNT, Carnegie Mellon Univ — Proximity effects attempting to combine electronic properties of graphene with exotic phenomena in other 2D van der Waals materials have been a central focus of condensed matter research for the past decade. To date, much work has been done studying proximity effects between graphene and ferromagnetic insulators, but little is known experimentally about the coupling between graphene and anti-ferromagnetic insulators. We report transport results from proximity devices consisting of graphene and α-RuCl$_3$, a layered anti-ferromagnetic Mott insulator predicted to host a so-called Kitaev quantum spin liquid. Upon cooling the device, the derivative of resistance with temperature shows a peak-dip feature. Depending on the gate voltage, this feature is seen anywhere from 35-50K, much higher than the Neel temperature of 14K. This could indicate a magnetic phase transition in the heterostructure.

8:36AM F51.00004: Emergent quantum Hall ground states driven by proximity exchange coupling in 2D material/ferromagnet interfaces*  DHAVALA SURI (Presenter), MASSACHUSETTS INSTITUTE OF TECHNOLOGY, ANDREW SAYDJARI, Harvard University, LINGYI ZHONG, Fudan University, SIDDHARTH OMAR, University of Groningen, ZHONGXUN GUO, Fudan University, MASON GRAY, Boston College, MIRKO ROCCI, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, KENNETH BURCH, Boston College, WENZHONG BAO, Fudan University, BART VAN WEES, University of Groningen, PATRICK A LEE, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, AMIR YACOBY, Harvard University, PENG WEI, University of California Riverside, JAGADEESH MOODERA, MASSACHUSETTS INSTITUTE OF TECHNOLOGY — In hBN/Graphene/EuS layer system we observe phase transitions spanning various quantum Hall regimes from quantum spin Hall edge state to anti-ferromagnetic state via an intermediate canted anti ferromagnetic (CAF) state. This is first demonstration of quantum Hall ferromagnetic ground states driven by proximity coupling with a ferromagnetic insulator (resulting in a huge exchange field) and achieved at a much lower applied magnetic field than any study in the past. The results clearly demonstrate the opening of edge state corresponding to CAF gap, while at much higher fields we observe reentrant insulating phase corresponding to the bulk gap as predicted by theory [1]. We also investigate the effects with WS2/Graphene/EuS stack. This led to interesting ground states emerging as a result of ferromagnet and SOC coupling induced by proximity effects. In this talk we will discuss the details of emergent ground state in 2D material/Ferromagnet interface effects along with future direction.

8:48AM F51.00005: Observation of Exchange bias effect in ferro-/antiferromagnetic van der Waals heterostructures*  CHANGGU LEE (Presenter), PAWAN KUMAR SRIVASTAVA, YASIR HASSAN, HYOBIN AHN, SOON-GIL JUNG, YISEHAK GEBREDINGLE, MINWOONG JOE, ABBAS SABBTAIN, BYUNGGIL KANG, TUSON PARK, Sungkyunkwan Univ, JE-GUEN PARK, Seoul National University, KYUNG-JIN LEE, Korea University — Recent discovery of magnetic van der Waals (vdW) materials offers an intriguing possibility for two-dimensional (2D) spintronics. An essential phenomenon for realizing 2D spintronics is the exchange bias effect in ferromagnet (FM)/antiferromagnet (AFM) vdW heterostructures. In a metallic FM /semiconducting AFM vdW heterostructure, we experimentally demonstrate that a finite exchange bias is maintained down to bilayer AFM and it vanishes at monolayer. Moreover, the semiconducting property of AFM allows us to electrically control the exchange bias, providing an energy-efficient knob for spintronic devices.

9:00AM F51.00006: Edge Effects in Transition Metal Dichalcogenides on Antiferromagnetic Substrates* NATALIA CORTÉS, Departamento de Fisica, Universidad Tecnica Federico Santa Maria, OSCAR AVALOS-OVANDO (Presenter), SERGIO E ULLOA, Department of Physics and Astronomy, Ohio University — We explore proximity-induced antiferromagnetism (AFM) on transition metal dichalcogenides (TMD), focusing on molybdenum ditelluride (MoTe$_2$) ribbons with zigzag and/or armchair edges, deposited on AFM substrates with diverse AFM orders, such as prospective candidates MnO, CoO or MnPX$_3$ (X = S; Se) substrates. We model the heterostructure in real space with a tight-binding model, incorporating the exchange and Rashba fields induced by proximity from the substrate. For the zigzag terminated TMDs, we find augmented Rashba SOC and Rashba type spin splittings for midgap states. For the armchair terminated TMDs, we find propagating pseudohelical edge modes, as well as either gapped or gapless edge modes depending on the ribbon’s width. We also explore the creation of spin polarized currents on these edges. These hybrid structures can serve as building blocks for spintronic devices and provide versatile platforms to further understand proximity effects in diverse materials systems.

9:12AM F51.00007: Partial Flatbands in a Spin-Orbit Coupled Twisted Bilayer Lieb Lattice AVADH SAXENA (Presenter), Los Alamos Natl Lab, SAIKAT BANERJEE, University of Augsburg — Topological classification of band-structure in various solid state materials has become one of the centerpieces of research in modern condensed matter physics. Typically, the specific topological nature of a dispersive band in a lattice system originates from a particular discrete symmetry present in the crystal. In this work, we analyze the topological properties of a partial/complete flatband in an apparently not so well known system -- a bilayer Lieb lattice. We demonstrate the emergence of flatbands with large Chern numbers in the presence of spin-orbit coupling. Our results are then contrasted with the flatbands in bilayer graphene and bilayer kagome lattice. We also consider a multi-layer Lieb lattice with even larger Chern numbers and speculate on the possibility of a superfluid phase in the presence of certain types of interactions.
9:24AM F51.00008: Yttrium-based Janus transition metal chalcogenides: Magnetic layered multiferroics*  PANKAJ KUMAR (Presenter), PRIYANKA MANCHANDA, PRATIBHA DEV, Howard University — The discovery of graphene in 2004 heralded the further discovery of hundreds of other two-dimensional (2D) materials, with a wide range of electronic and optical properties. Till recently, however, it was believed that magnetism cannot exist in 2D materials, in keeping with the Mermin-Wagner Theorem. This changed with the observation of long-ranged magnetism in a few 2D materials, such as CrI$_3$ and Cr$_2$Ge$_2$Te$_6$. This has started an active search for additional magnetic 2D crystals. In this talk, we present our theoretical research on a new class of magnetic 2D materials - Yttrium-based Janus transition metal chalcogenide (TMD) semiconductors. As a prototype of these materials, we studied properties of the YSSe Janus structure. YSSe has a magnetic moment of 1μ$_B$/formula unit (f.u.), and an in-plane magneto-crystalline anisotropy energy of 162 μeV/f.u. Along with broken time reversal symmetry, a YSSe layer also lacks mirror symmetry. Hence, it exhibits ferroelectricity, with a polarization that can be switched under the application of strain, making it a promising candidate material for ultra-compact spintronic and multiferroics-based devices.

9:36AM F51.00009: Enhanced Zeeman splitting in MoS$_2$ monolayers doped with transition metals.  ARINJOY BHATTACHARYA (Presenter), MENGYING BIAN, ARMAN NAJAFI, PEIJIAN WANG, ALIREZA JALOULI, Physics, State Univ of NY - Buffalo, Buffalo, New York, JIEQIONG WANG, MOE Key Laboratory of Nonequilibrium Synthesis and Modulation of Condensed Matter, Xi’an Jiaotong University, China, JIADONG ZHOU, Materials Science and Engineering, Nanyang Technological University, Singapore, SEN YANG, MOE Key Laboratory of Nonequilibrium Synthesis and Modulation of Condensed Matter, Xi’an Jiaotong University, China, ZHENG LIU, Materials Science and Engineering, Nanyang Technological University, Singapore, HAO ZENG, ATHOS PETROU, Physics, State Univ of NY - Buffalo, Buffalo, New York — We developed an approach to dope MoS$_2$ monolayers with controllable concentration of transition metal ions. In this approach, a single phase transition metal-doped MoO$_3$ compound precursor was utilized to deposit ultrathin doped MoO$_3$ film by electron beam evaporation, followed by sulfurization of the precursor oxide layer to achieve monolayer transition metal doped MoS$_2$.

We have used magneto-reflectance spectroscopy to compare the Zeeman splitting of MoS$_2$ monolayers with that of MoS$_2$ doped with transition metals. At T = 7K we find that the A-exciton Zeeman splitting in the doped sample is 23% higher that of the undoped MoS$_2$. The enhancement is attributed to exchange interaction between the spins of carriers and those of the transition metal ions.
9:48AM F51.00010: Optical rotation in thin chiral/twisted materials and the gyrotropic magnetic effect  YANQI WANG (Presenter), University of California, Berkeley, TAKAHIRO MORIMOTO, Applied physics department, University of Tokyo, JOEL MOORE, University of California, Berkeley — The rotation of the plane of polarization of light passing through a non-magnetic material is known as natural optical activity or optical gyrotropy. The behavior of this effect in thin conductors is of current interest. For example, the low frequency limit of gyrotropy in chiral 3D crystals, known as the gyrotropic magnetic effect (GME), is controlled by the orbital magnetic moment of electrons, which has been proposed to be relevant to switching in twisted bilayer graphene. We show that the GME is not limited to bulk materials but also appears for quasi-2d systems with minimal structure incorporated in the third direction. Starting from multi-band Kubo formula, we derive a generic expression for GME current in quasi-2d materials induced by low-frequency light, and provide a Feynman diagrammatic interpretation. The relations between the 2d finite layered formula and 3d bulk formula are also discussed.

Influence of interface-induced spin-orbit interaction on transport in graphene-on-WSe$_2$ heterostructures* MUHAMMAD ZUBAIR (Presenter), Department of physics, Concordia University, MUHAMMAD TAHIR, Department of physics, Colorado State University, PANAGIOTIS VASILOPOULOS, Department of physics, Concordia University — Proximity effects in graphene/transition-metal dichalcogenides heterostructures are expected to play a major role in the fields of spintronics and valleytronics. We investigate the electronic dispersion of such heterostructures in the presence of a proximity induced spin-orbit interaction (SOI) using a tight-binding (TB) model. The competition between different perturbation terms leads to inverted bands, when graphene is on WSe$_2$, and to topologically trivial band structures when it is placed on MoS$_2$, MoSe$_2$, and WS$_2$. In addition, we study the effect of symmetry breaking terms on ac and dc transport by evaluating the corresponding conductivities within linear response theory. The scattering-dependent diffusive conductivity increases linearly with electron density but weakens as the screening gets stronger. Further, we evaluate the power spectrum and assess its dependence on the spin and valley degrees of freedom and on the scattering which is essential at low frequencies.

Flavor Quantum Dots and Artificial Quark Model in Transition Metal Dichalcogenides* ZHI-QIANG BAO (Presenter), PATRICK CHEUNG, FAN ZHANG, University of Texas at Dallas — We show that the triply degenerate Q valleys in few-layer transition metal dichalcogenides provide a unique platform for exploring the rare flavor SU(3) symmetry in quantum dot geometry. The single and double dots are reminiscent of the quark model and eightfold way, and their many-body triplets and octets may be regarded as artificial quarks and hadrons. For the artificial quark transistor, each level hosts one central and two side Coulomb peaks of irrational height ratios, and flavor Kondo effects occur at 1/3 and 2/3 fillings with fractional conductance quantization in the unitary limit.

10:36AM F51.00014: Exchange Interaction Between Magnetic Adatoms in Irradiated Graphene* MODI KE (Presenter), MAHMOUD M. ASMAR, WANG KONG TSE, Univ of Alabama - Tuscaloosa — We present a theory for the non-equilibrium RKKY interaction in graphene irradiated by circularly polarized light. A k.p theory of the graphene Floquet Hamiltonian is developed, which provides a successive approximation scheme as the light-matter coupling strength is increased. Based on the Floquet k.p Hamiltonian, we calculate the real-space Floquet Green’s functions and the time-averaged RKKY interaction using Floquet-Keldysh formalism. We find that optical illumination generally suppresses the exchange interaction in undoped graphene, due to a band gap opened at the Dirac point. Results for doped graphene will also be presented.

*This work is supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Early Career Award #DE-SC0019326.

F51.00015: Spin-Induced Optical Anisotropy on van der Waals Antiferromagnet* XINGZHI WANG (Presenter), JUN CAO, HIKARI KITADAI, TIANSHU LI, XI LING, Boston Univ — Two-dimensional (2D) magnetic systems have received growing interest revealing new physics of magnetism in the nanoscale limit. As an important family of van der Waals magnetic materials, metal phosphorus chalcogenides have attracted intense attention due to the intrinsic antiferromagnetism and the electronic bandgap in the visible range. Recently, we observe a strong anisotropy on optical absorption in 2D antiferromagnet, nickel phosphorus trisulfides (NiPS₃), which is induced by its spin structure in the antiferromagnetic phase. The temperature and polarization dependent study indicates the strong correlation between electronic and magnetic structure. A control experiment has been conducted on the other compounds in this family, which further supports our conclusion. Our studies reveal the unique electronic and magnetic properties of NiPS₃, paving the way for potential functionalities and applications of 2D magnetic materials.

1E - Emily Bittle, National Institute of Standards and Technology
8:00AM F52.00001: Work Function Studies of Carbon Nanospikes for Electrochemistry by UPS* ARTHUR BADDORF (Presenter), YANG SONG, DALE K. HENSLEY, ADAM J. RONDINONE, Oak Ridge National Lab — Carbon nanospikes show excellent energy and selectivity for electrochemical conversion of CO$_2$ to ethanol$^1$ and N$_2$ to NH$_3$.$^2$ Reactivity is attributed to physical structure more than composition. A spike geometry concentrates the electric field, promoting local electroreduction of reaction molecules. Using UPS, we have measured the work function of carbon nanospikes transferred to vacuum after extraction from a N$_2$-saturated LiClO$_4$ electrolyte at a range of potentials. The work function exhibits a general decrease with increasing negative emersion potential. The decrease is not 1:1 eV/V to the applied potential, nor is it linear. This may reflect imperfect double layer retention during transfer through air and into vacuum. In most cases, UPS spectra were typical, with an obvious low-energy cutoff. However, for several samples, including the pristine nanospikes, two cutoffs appeared to exist, one suggesting a much lower work function. The nature of the low-energy cutoff and possible connection to the geometry will be discussed.

** A portion of this research was conducted at the Center for Nanophase Materials Sciences, which is a DOE Office of Science User Facility.

8:12AM F52.00002: Structural and Electrical Factors of the Photocatalytic Activity of Bi$_2$WO$_6$ and Bi$_2$MoO$_6$ in Water-Splitting Applications* STEVEN BAKSA (Presenter), Pennsylvania State University, QUINN CAMPBELL, Sandia National Laboratories, ISMAILA DABO, Pennsylvania State University — Artificial photosynthesis is a sustainable technological option to store solar energy through the photocatalytic conversion of carbon dioxide and water into chemical fuels. The main challenges with this photocatalytic process include tuning the band gap of the material to match the solar spectrum and ensuring its stability in aqueous environments. An appealing approach for developing such photocatalysts consists of intercalating functional layers into metal oxides, as is the case for perovskite-derived compounds of the Aurivillius (Bi$_2$A$_{n-1}$B$_n$O$_{3n+3}$) family, which have been shown to be photoactive under visible light. Using density-functional theory, we predict the nanosheet morphology of Bi$_2$WO$_6$ and Bi$_2$MoO$_6$ under applied voltage, and we provide a molecular description of the charged interface under controlled pH and applied voltage. This study offers a molecular interpretation of the competing structural and electrical factors that underlie the facet-dependent photocatalytic activity of layered Bi$_2$A$_{n-1}$B$_n$O$_{3n+3}$ compounds.

Density Functional Theory Studies of Protective Interlayer of Graphene for the Back Contact of Copper Zinc Tin Sulphur Thin Film Solar Cell* YAU LUN FELIX CHONG (Presenter), JUNYI ZHU, Chinese Univ of Hong Kong — CZTS(Se) based solar cell is one of the promising candidates in the development of the 3rd generation solar cell absorbers. However, the efficiency of CZTS is insufficient for commercial product. One of the major causes of low performance is poor back contact-absorber interface quality. During annealing process of CZTS, S atom diffuses into Mo back contact layer and form a detrimental secondary phase of MoS₂. Interlayer engineering has been proposed. However, most of the proposed interlayers are based on insulating systems. Here, we propose a new protective material of graphene as an effective diffusion barrier to block any S atom diffusion. Using Climbing Image Nudged Elastic Band Method based on Density Functional Theory calculation to find diffusion barrier and minimum energy path, we can show that the choice of our protective layer can effectively block S atoms diffusion under fabrication and operation environment. We also calculated the band alignment between the proposed protective interlayer and CZTS absorption layer. The results suggest the protective interlayer we proposed will not significantly degrade the performance of the solar cell.

The Electromagnetic Enhancement of SERS and the Modified Partition of Optical States in the Strong Matter-Coupling Regime. KRITIKA JAIN (Presenter), MURUGESAN VENKATAPATHI, Indian Institute of Science — Surface enhanced Raman Spectroscopy (SERS) is a powerful optical sensing technique that is based on enhanced Raman signals from molecules in proximity of rough metal surfaces. Experiments¹ have shown unexpected large enhancements in SERS, even up to 10¹⁴. Conventional electromagnetic theory accounts for enhancements only up to 10⁶, and the anomalous enhancements have even been attributed to an unknown chemical origin²,³. We show that when one includes dynamics in fluctuations of an emitter strongly coupled to absorbing matter, such high gains are predicted due to tunneling out of photons from the strongly absorbing metal surface. This modification to the conventional partition of optical states into its radiative and non-radiative parts, is also imperative for emitters proximal to limiting small metal nanoparticles (< 10 nm in dimensions) which are fully absorbing. Some recent experiments have shown such anomalous gains in emission due to these extremely small nanoparticles. This effect can be exploited further in light generation, optical sensing and radiative heat transfer.

8:48AM F52.00005: Protecting high quantum efficiency photocathodes with two dimensional materials for long lifetimes*  GAOXUE WANG, Theoretical Division, T-1, Los Alamos National Laboratory, NATHAN A MOODY, AOT Division, Los Alamos National Laboratory, PING YANG, Theoretical Division, T-1, Los Alamos National Laboratory, ENRIQUE BATISTA (Presenter), Theoretical Division, CNLS, Los Alamos National Laboratory — Since soon after the discovery of the photoelectric effect, the goal of reaching highly efficient photoelectron emission has been a difficult and well sought out goal. Currently, applications such as XFEL and XERL, call for high intensity electron sources that can lead to bright and intense electron and x-ray beams. The intensity of the photoemitted beam, the quantum efficiency of the photocathode, is dominated by the absorption cross section, electron mobility, and surface work function. For practical reasons, the lifetime of the photocathode is important and long-lived photocathodes are very much sought to improve performance. Whereas alkali-based semiconducting photocathodes display much higher QE relative to metal surfaces, their chemical composition makes them very reactive to residual gases even at UHV conditions. We will discuss here approaches for neutralizing such reactivity on the surface not introducing higher barriers to the emitted electrons. A computational study will be presented for screening 2-dimensional coating materials and fundamental principles for the characteristics needed are extracted. We present not only design principles but also candidate materials that should be used for protecting these highly reactive surfaces

*LANL LDRD program

9:00AM F52.00006: Defect mediated self-powered, broad band and ultrafast InGaN based photodetector*  ARUN CHOWDHURY (Presenter), ROHIT PANT, Materials Research Centre, Indian Institute of Science, BASANTA ROUL, Central Research Laboratory, Bharat Electronics, DEEPEndRA KUMAR SINGH, KARUNA KAR NANDA, SALURU BABA KRUPANIDHI, Materials Research Centre, Indian Institute of Science — In this work, Si doped n+-InGaN epilayer has been grown on a 100 nm thick AlN template on an n-type Si (111) substrate to form semiconductor-insulator-semiconductor (SIS) heterostructure by plasma-assisted molecular beam epitaxy (PAMBE). The n+-InGaN/AlN/n-Si (111) device shows excellent self-powered and broad band photo response under UV-Visible (300-800 nm) light illumination and maximum response is observed at 580 nm for low intensity irradiance (0.1 mW/cm²), owing to the intermediate energy states present in InGaN lattice due to nitrogen vacancies. At zero bias, the device exhibits a high responsivity of 9.64 A/W with ultrafast rise and fall times of 19.9 and 21.4 μs, respectively. This is the highest reported responsivity for the InGaN based photodetectors at zero bias to best of our knowledge. Introduction of AlN buffer layer and doping enhance the photoelectrical properties of the device compared to other conventional detectors. This work opens up a new avenue for SIS heterojunction photo detectors with much improved performance as self-powered and broadband detectors over the previously reported values on InGaN.

9:12AM F52.00007: The Effect of Au Nanoparticles on the Photovoltaic Conversion Efficiency in CdTe/CdS Thin Films*

YUNIS YILMAZ (Presenter), NOELLE SCHILLING, STEPHANE ARSHARUNI, MEHMET ALPER SAHINER, Physics, Seton Hall University — In our last study, we have worked on the effects Ag and Au nanoparticles have on the efficiency of CdS/CdTe thin film solar cells. Both had a positive effect on the efficiency of photovoltaic conversion. Now, we are testing Au nanoparticles on the same cells and plan on comparing the effects of different deposition times, and laser energy on the Au, and how it effects efficiency and Au nanoparticle size. We used PLD (pulsed laser deposition) to create these cells. The laser shoots the target material we want to deposit (CdS,Au,CdTe) turning it into plasma plume that deposits onto ITO (indium tin oxide) coated glass. Varying how long the laser shoots at the Au and at what energy changes the amount of Au deposited and the size and distribution of the particles as well. The more Au in the np junction, the more the increase in the efficiency of the solar cell due to plasmonic resonance effects. However, the efficiency cuts off with after a threshold value for Au deposition. Our last study concluded that we had already passed this saturation point, so now, we are testing lower deposition lengths and energies. The Au embedded cells were characterized by XRD, AFM, SEM/EDX, and a sourcemeter setup.

9:24AM F52.00008: Development of Molybdenum Nitride Thin-Films on Metal Substrates*

MUHAMMAD SAJID (Presenter), ASIM KHANIYA, WILLIAM KADEN, ABDELKADER KARA, Univ of Central Florida — Molybdenum Nitride exceeds in catalytic activity and product selectivity from industrial grade catalysts for Hydrodenitrogenation (HDN), removal of nitrogen from petroleum feedstocks. δ-MoN is suggested to be more active than bulk γ-Mo_2N phase, but more work is needed to better understand the relation between activity and atomic structure of catalysts. We are using DFT with added vdW effects, to study adsorption of both phases on metal substrates, having minimal lattice mismatch. Through Nudged Elastic Band (NEB) Calculations, reaction pathways and energy barriers of HDN reaction mechanisms of pyridine (simplest N containing aromatic molecule) will to studied. Thin films of catalyst phases will be developed under Ultra-High Vacuum (UHV) and studied via spectroscopic techniques (XPS, LEED, ISS, STM) and fixed or variable temperature mass spectrometry. Predictions from theory will be directly compared and verified with experimental observations. Combination from both theory and experiments will aid us towards reaching to the subtle connection between atomic structure and desired catalytic properties.

*American Chemical Society Petroleum Research Fund, Partial support is from U.S. Department of Energy under Award number DE-SC0007045. Computational resources of NERSC and UCF-Stokes.
DEEPENDRA SINGH (Presenter), ROHIT PANT, ARUN CHOWDHURY, BASANTA ROUL, KARUNA KAR NANDA, SALURU BABA KRUPANIDHI, Indian Institute of Science — Efficient photodetectors require high and fast photo-response as well as low power consumption. In the present work, we have demonstrated MoS$_2$/GaN nanorods/Si based self-powered and most importantly, spectrally distinctive photodetector. GaN nanorods were grown on Si (111) by Volmer-Weber type growth conditions using plasma-assisted molecular beam epitaxy, followed by growth of MoS$_2$ by pulsed laser deposition. HRTEM analysis shows MoS$_2$ has been incorporated on the top and sides of the nanorods, as well as in between them on Si. The device with top-bottom electrodes shows a maximum responsivity of 10.67 A/W at 900 nm in zero bias condition. The response and the recovery times have been estimated to be 30.9 and 33.9 μs, respectively. The spectral response studies also revealed that in the range of infrared wavelength (1000 - 1050 nm), there is an inversion (positive to negative) in the photocurrent. A mechanism based on illumination modulated activation of barriers, and the interaction of MoS$_2$ with GaN and Si has been discussed to explain the observed phenomenon of polarity inversion.

*Deependra Kumar Singh acknowledges Council of Scientific & Industrial Research, New Delhi for providing senior research fellowship.

SU JEONG HEO (Presenter), MEAGAN PAPAC, ANDRIY ZAKUTAYEV, National Renewable Energy Laboratory — Proton-conducting solid oxide electrolysis cell (H-SOEC) is of increasing interest as a result of its promising electrochemical application that efficiently converts electrical energy to chemical energy. However, the poor anode activity towards the water-splitting reaction is still the hindrance of the overall performance of H-SOCEs. In this study, novel perovskite Ba(ZrYPr)O$_3$-δ (BZYP) materials are investigated as the anode for the electrolysis cell to improve its proton-conducting ability. We used high-throughput experimental technique to reveal the chemical and electrical properties of BZYP perovskite and identify their appropriate composition for effective water splitting application. The BZYP combinatorial libraries films are synthesized using combinatorial pulsed laser deposition (PLD) and characterized by spatially resolved techniques for composition, structure, thickness, and electrical properties. Overall, through innovative material discovery and characterization using HTS, an anode with extensively broadened reactive sites will be developed for proton-conducting solid oxide electrolysis cells applications.

*This work was supported by the U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy (EERE) under the contract number DE-EE0008378.
10:00AM F52.00011: Optical properties and carrier transport in graphene-mesoporous silicon nanocomposites  DÉFI JUNIOR JUBGANG FANDIO (Presenter), Physique, Université de Sherbrooke — Graphene outstanding properties has been used to enhance the performance of various optoelectronic devices, in particular the field of photovoltaics [1]. In this work, we investigate the optical properties and charge carrier transport of mesoporous silicon nanocomposites coated with few—layer graphene. Photoconductivity properties and carrier capture/recombination dynamics of the photocarriers in these films are studied via optical pump-terahertz probe measurements. Our results show influence of carbon deposition temperature on the Si nanocrystallites luminescence bands as well as the appearance of new higher energy emission bands. The carrier recombination dynamics is largely affected by the presence of defects at the Si/graphene interface. The frequency dependent photoconductivity curves are well reproduced by the Drude-Smith model, like that used for studying the properties of a film composed of Si nanoparticles dispersed in an oxide matrix [2]. The relatively high mobility and low carrier recombination time in these nanostructures make them good candidates for THz photoswitch applications.

10:12AM F52.00012: The Role of Metal-Semiconductor Interface in Hybrid Perovskite Devices for High-Performance Solid-State Detectors*  SHREETU SHRESTHA (Presenter), Hsinhan Tsai, Michael YoHo, Fangze Liu, Los Alamos National Laboratory, Yusheng Lei, University of California, San Diego, Jon Baldwin, Sergei Tretiak, Ducta Vo, Wanyi Nie, Los Alamos National Laboratory — Hybrid perovskites have emerged as excellent semiconductors enabling efficient opto-electronic devices. Apart from the intrinsic properties of the semiconductor, interfaces are critical to make a superior device. Here, we use scanning photocurrent microscopy on lateral methylammonium lead triiodide (MAPbI) single crystal devices with commonly used high work function metal and low work function metal contacts to investigate perovskite-metal interfaces. By comparing the spatially resolved photocurrent maps of devices with Au (high work-function metal) to Pb (low work-function metal), we find that a Schottky barrier exists in both cases and the barrier is higher for the Pb/perovskite junction resulting in a lower leakage current. From the decay of the photocurrent profile near the metal contacts, we estimate charge carrier diffusion length to be 9 ± 2 µm. Using this knowledge, we successfully demonstrate a single crystal MAPbI gamma ray detector from which sharp gamma-ray induced pulses are observed. Our study indicates that the interface plays a significant role especially in solid state detector operating at low flux photon counting mode.

**10:24AM F52.00013: p-Diamond as a plasmonic material for high frequency applications**

SERGEY RUDIN (Presenter), GREG RUPPER, TONY G. IVANOV, US Army Rsch Lab - Adelphi, MICHAEL S SHUR, Rensselaer Polytechnic Institute — The gate-controlled hole gas at the hydrogenated diamond surface was predicted to have a plasmonic response to a terahertz and sub-terahertz electric field, making p-diamond field effect transistors promising candidates for implementing room temperature plasmonic devices. The predicted performance of diamond plasmonic detectors shows their potential for high temperature, high voltage, and radiation hard applications and for THz communications and spectroscopy. The hole mobilities in our samples allow for a room temperature resonant plasmonic response. It makes possible the realization of p-diamond based emitters in terahertz and sub-terahertz range, using strong current driven plasma instability in gated channels. Toward the optimal design of p-diamond plasmonic devices we simulated the response using the complete set of hydrodynamic equations, including the thermal transport and accounting for effects of viscosity and pressure gradients. In the strong signal regime we find that a shock wave develops in the charge density and drift velocity profiles. Due to high value of the dielectric breakdown field in diamond the diamond plasmonic device can operate in the strong signal regime, when a shock wave propagates in the channel.

**10:36AM F52.00014: Influence of headgroup and chain length on the surface freezing behavior of long chain amphiphiles**

SARANSHU SINGLA (Presenter), AMANDA STEFIN, HE ZHU, ALI N DHINOJWALA, Univ of Akron — Long-chain polar amphiphiles such as alcohols and amines form a finite contact angle on high-energy solid surfaces on account of formation of an oriented monolayer, as opposed to expected complete wetting. Previous experiments with octadecanol (and hexadecanol) suggest that the monolayer formed on alumina displays surface freezing behavior on account of strong headgroup-substrate interactions. However, the data for different headgroups and chain lengths is elusive in literature. In the present study, we investigate the combined effect of headgroup-substrate interactions and chain length on the observed surface freezing behavior using interface-sensitive sum frequency generation spectroscopy (SFG). SFG provides information about ordering of amphiphilic molecules at the sapphire-melt interface along with interaction strength of different headgroups with sapphire. Our study provides insights into the fundamental mechanism of monolayer formation.

Molecular beam epitaxial growth of high quality BeMgZnO single crystal films for ultraviolet photodetectors

YIFEI FANG (Presenter), Key Laboratory of High Power Laser Materials, Shanghai Institute of Optics and Fine Mechanics, Chinese Academy of Sciences, LONGXING SU, Department of Materials, Sun Yat-Sen University, MIN XU, YIN HANG, Key Laboratory of High Power Laser Materials, Shanghai Institute of Optics and Fine Mechanics, Chinese Academy of Sciences — High quality ZnO single crystal films and alloy films were prepared on sapphire substrate by molecular beam epitaxy. By studying the influence of growth parameters on quality, components and defect density of the film, repetitive and controllable epitaxial growth conditions were obtained, and the possible positions and effects of doping elements, Be and Mg, in the crystal were further studied. The high quality of film was verified by RHEED and TEM. It is found that with small ionic radius Be doped in the lattice is easy to produce lattice distortion, and has a certain probability of entering the interstitial position. However, Mg atoms have high solid solution in ZnO. Photoconductive, schottky junction and heterojunction UV photodetectors were further prepared and their physical properties were systematically studied. We found that the response speed of the device is greatly slowed down due to the space charge layer caused by O₂ adsorption, and the response time is optimized to a scale of microsecond by Be doping. Heterojunction devices have the advantages of self-drive and ultra-fast response, which can be used as self-powered devices in some unmanned and harsh working environments. This research gives guidance for application of ZnO in semiconductor optoelectronic devices.

Tuesday, March 3, 2020 8:00 AM - 11:00 AM

Session F53 DCMP: Transport Properties of 2D Materials

Alexey Lipatov

A hidden quantum phase in two-dimensional WTe₂

SANFENG WU (Presenter), Princeton University — Correlations, spin-orbit coupling and topology are all important in the atomically thin WTe₂ layers. In this talk I will introduce our recent quantum transport studies of two-dimensional WTe₂ where we discover a hidden quantum phase.

*This research was supported by NSF through the Princeton University Materials Research Science and Engineering Center DMR-1420541
8:12AM F53.00002: Anisotropic magnetotransport in few-layer Nb-doped WSe$_2$

HIROYUKI NAKAMURA (Presenter), University of Arkansas, AVAISE MOHAMMED, WILFRIED SIGLE, YI WANG, PETER WOCHNER, Max Planck Institute for Solid State Research, JOHN VILLANOVA, JEB STACY, SALVADOR BARRAZA-LOPEZ, HUGH CHURCHILL, University of Arkansas, PETER VAN AKEN, HIDENORI TAKAGI, Max Planck Institute for Solid State Research — Hole-doped epitaxial WSe$_2$ films with thicknesses of three to six monolayers were grown by a hybrid pulsed-laser deposition, in which metallic alloy targets were laser-ablated under a controlled Se vapor. The Hall effect indicated active Nb-dopant concentrations of 10-50 at%. Scanning transmission electron microscopy revealed that Nb atoms occupy W sites, and 2H- as well as 3R-stacking coexist in the films. A striking anisotropy between magnetoconductance (MC) for in-plane (B // I) and out-of-plane (B ⊥ I) magnetic fields was found, showing a complete absence of weak antilocalization for B ⊥ I, while it restores for B // I at intermediate temperatures. The band structure of 2H-3R Nb:WSe$_2$ obtained by first-principles calculations is shown, based on which a few possible origins of the MC will be discussed.

8:24AM F53.00003: Observation of monolayer-like quantum transport in few-layer MoS$_2$

TIANYI HAN (Presenter), XU HAN, JIANGXIAZI LIN, Physics Department, Hong Kong University of Science and Technology, BENJAMIN A. PIOT, Laboratoire National des Champs Magnétiques Intenses, XIANGBIN CAI, DING PAN, JUNWEI LIU, NING WANG, Physics Department, Hong Kong University of Science and Technology — The conduction band minimum of MoS$_2$ shifts from K valley to Q valley when its thickness increases from monolayer to bulk. Previously, K valley quantum transport has been extensively studied in monolayer MoS$_2$, revealing its intriguing physical properties such as the spin-valley locking effect and the interaction enhanced Zeeman splitting. However, the fabrication of monolayer MoS$_2$ device requires considerable efforts mainly due to the challenges of achieving good electrical contact. Here we report the observation of monolayer-like K valley quantum transport in high quality few-layer MoS$_2$. Well-developed two-fold quantum oscillations are presented, with valley Zeeman splitting and spin polarized Landau levels at high magnetic field. Further, we observe multi K band conduction in the Landau fan diagram, from which the spin-orbit coupling splitting energy is estimated. Our observation offers the possibility of switching from Q valley to K valley transport in few-layer MoS$_2$.

We acknowledge the technical support from the Raith-HKUST Nanotechnology Laboratory and the support of the LNCMI-CNRS, member of the European Magnetic Field Laboratory (EMFL).
8:36AM F53.00004: Preferential out-of-plane conduction and quasi-one-dimensional electronic states in layered van der Waals material 1T-TaS$_2$  EDOARDO MARTINO (Presenter), KONSTANTIN SEMENIUK, ALLA ARAKCHEEVA, CARSTEN PUTZKE, PHILIP MOLL, HELMUTH BERGER, Ecole Polytechnique Federale de Lausanne, IVO BATISTIC, University of Zagreb, EDUARD TUTIŠ, Institute of Physics - Zagreb, ANA AKRAP, University of Fribourg, LASZLO FORRO, Ecole Polytechnique Federale de Lausanne — Layered metallic transition-metal dichalcogenides are conventionally seen as two-dimensional conductors, despite a scarcity of systematic studies of the interlayer charge transport. Motivated by the ascending strategy of functionalizing 2D materials by vertical heterostructures we initiated an in-depth study of out-of-plane charge dynamics and emergent properties arising from interlayer coupling. Here, we reveal c-axis-oriented quasi-one-dimensional electronic states in 1T-TaS$_2$, a layered system hosting a plethora of diverse phases, by probing its out-of-plane electrical resistivity using focused-ion-beam-tailored crystals. The in-plane conduction appears non-metallic due to presence of a unique nanoarray of charge density wave (CDW) domains. All the while, the interlayer resistivity has a metallic temperature dependence with the anisotropy close to one, as a result of intertwining of the orbital and CDW orders. The compound is known for what was believed to be a Mott-type localisation below 150 K. Yet with our data, supplemented by ab-initio calculations, we interpret the transition as a Peierls-like instability of the quasi-one-dimensional electronic structure. Our findings present a very unintuitive behaviour in a van der Waals crystal.

8:48AM F53.00005: Band filling and cross quantum capacitance in ion gated semiconducting transition metal dichalcogenide monolayers  HAIJING ZHANG (Presenter), Physics of Quantum Materials, Max Planck Institute for Chemical Physics of Solids, CHRISTOPHE BERTHOD, Department of Quantum Matter Physics, University of Geneva, HELMUTH BERGER, Institut de Physique de la Matiere Complexe, Ecole Polytechnique Federale de Lausanne, THIERRY GIAMARCHI, ALBERTO MORPURGO, Department of Quantum Matter Physics, University of Geneva — Ionic liquid gated field-effect transistors based on semiconducting transition metal dichalcogenides are attracting significant scientific interest, but important aspects of how charge carriers are accumulated in these systems remain elusive. Here we present a thorough analysis of charge accumulation in MoSe$_2$ and WSe$_2$ monolayers. We identify the conditions when the chemical potential enters different valleys in the monolayer band structure (the K and Q valleys in the conduction band and the two spin-split K-valleys in the valence band) and find that an independent electron picture describes the occupation of states well. Unexpectedly, however, the same analysis shows that the total device capacitance cannot be simply described in terms of the series connection of a geometrical capacitance and of a quantum capacitance given by $C_Q = e^2/(d\mu/dn)$, as commonly assumed. This unexpected behavior is attributed to the presence of a cross quantum capacitance, which originates physically from mutual screening of the electric field generated by charges on one plate from charges sitting on the other plate. Our findings therefore reveal an important contribution to the capacitance of physical systems that had been virtually neglected until now.
2e charge transport in a quantum Hall - superconductor junction revealed by shot noise

MANAS SAHU (Presenter), ARUP KUMAR PAUL, JAGANNATH SUTRADHAR, Department of physics, Indian Institute of Science, Bangalore 560012, India, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute of Material Science, 1-1 Namiki, Tsukuba 305-0044, Japan, SUBROTO MUKERJEE, SUMILAN BANERJEE, ANINDYA DAS, Department of physics, Indian Institute of Science, Bangalore 560012, India — Two remarkable phenomena of condensed matter physics, the quantum Hall (QH) effect and superconductivity, when combined, can give rise to exotic topological excitations and hold great promises for future quantum computation. Andreev reflection (AR) is the underlying phenomena, which determines the quasiparticle dynamics at the QH–superconductor (SC) junction. Even decades after the discoveries of QH and SC, the AR at the QH-SC junction remains elusive. Here we have carried out conductance and shot noise measurements in a graphene QH coupled to a MoRe superconductor. The QH plateaus are observed at 4(N+1/2)e^2/h, which are identical to the conductance plateaus with a normal contact. This observation is consistent with our theoretical calculation of electron-hole mixing due to repetitive AR at QH - SC junction. By measuring shot noise, we observe the Fano factor close to unity when the bias energy is less than the superconducting gap. This is direct evidence of 2e charge transport at QH - SC junction. Above the superconducting gap, the Fano factor almost vanishes, as expected due to regular charge e transport. This work will pave the way for exploration of more exotic systems, such as junction of a fractional QH and a superconductor, by shot noise measurements.

Direct measurement of layer polarizability in a van der Waals ferroelectric semimetal

QINGRUI CAO (Presenter), SERGIO C DE LA BARRERA, VINEETHA BHEEMARASETTY, Department of Physics, Carnegie Mellon University, JIAQIANG YAN, Materials Science and Technology Division, Oak Ridge National Laboratory, DI XIAO, YANG GAO, BENJAMIN HUNT, Department of Physics, Carnegie Mellon University — A ferroelectric semimetal has coexistence of spontaneous electric polarization and metallicity. A recent study [1] demonstrated bilayer and trilayer 1T'-WTe₂ exhibit an out-of-plane switchable polarization using graphene as an electric-field sensor. However, a direct measurement of its layer polarizability is still lacking. Here, we detect and quantify the ferroelectricity by layer-resolved capacitance measurements [2] in dual-gated bilayer WTe₂, allowing us to control applied electric field and charge density independently. Moreover, we examine the density-dependent polarizability and extract the critical densities above which the polarization becomes weaker. All of our observations, including hysteresis, "near-layer capacitance enhancement", density dependence of the polarization, are consistent with the theoretical predictions based upon an electrostatic model of capacitance derived from a "tilted-Dirac-cone" model of bilayer WTe₂.

9:24AM F53.00008: Electron-phonon scatterings and their roles in vertical charge transport through van der Waals heterostructures  
SU Yong JUNG (Presenter), Korea Research Inst of Standards and Science (KRISS) — Electron–phonon scattering in solid-state systems is a pivotal process in determining many of key physical quantities such as charged carrier mobilities and lattice thermal conductivities. Here, we report electron tunneling measurements with a semiconducting transition metal dichalcogenide, WSe$_2$, as the tunnel medium. In van der Waals (vdW)-coupled vertical heterostructures, inelastic quantum tunnel events activated by turbostratic electron–phonon scatterings constructively establish an adjunct transport channel, which drastically increases its loads in vertical charge flows with increasing tunnel medium thickness. Phonons interacting with the tunnel electrons are layer-number dependent, varying by monolayer vs. bi- and triple-layer WSe$_2$, with an out-of-plane flexural ZA mode as the common excitation. In addition, we find out that second-order electron–phonon scatterings become conspicuous in the multilayered films, involving assorted phonons in the tunnel media and the vDW heterojunctions.

9:36AM F53.00009: Orientation-dependent transport and Goos-Hanchen effect in phorsphorene  
LI RuiGang (Presenter), University of Science and Technology of China, KWOK SUM CHAN, City University of Hong Kong, ZIJING LIN, University of Science and Technology of China — By using the continuum model, we systematically investigate the transport property in the phorsphorene NPN junction. Different devices with different angles between the ribbon and armchair directions are studied. With the increase of this angle from 0°, it is found that the transmission first exhibits the oscillating behavior. Particularly, with the further increase of the angle close to 90°, the transmission goes through a fast drop to zero. We further find that the fast drop arises from the transformation of the transporting carriers from the Dirac quasiparticles into Schrodinger ones, and the angel of this transformation is related to the anisotropy of the effective mass, providing the possibility to shed light on the electronic device design. Furthermore, study of the Goos-Hanchen effect in the phorsphorene NPN junction is also addressed. It is interesting to find that even for the slight change of the angle between the ribbon and armchair directions, remarkable change of the incoming wave pocket is obtained, providing the promising candidate as the wave-pocket-selected filter. Finally, all above properties in NN’N junctions of the bulk phorsphorene are also addressed.
9:48AM F53.00010: Anomalous Coulomb Drag between InAs Nanowire and Graphene Heterostructures  
RICHA MITRA (Presenter), MANAS SAHU, Department of Physics, Indian Institute of Science, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Namiki 1-1, Ibaraki 305-0044, Japan., HADAS SHTRIKMAN, Department of Physics, Weizmann Institute of Technology, Israel, A K SOOD, ANINDYA DAS, Department of Physics, Indian Institute of Science — Correlated charge inhomogeneity breaks the electron-hole symmetry in two-dimensional bilayer heterostructures, responsible for non-zero drag appearing at the charge neutrality point. Although several theories predict this phenomenon, there is no consensus over the actual mechanism responsible for it. Here we report, Coulomb drag in a novel drag system consisting of a two-dimensional (2D) graphene and a one dimensional (1D) InAs nanowire (NW) heterostructures. For monolayer graphene (MLG)-NW heterostructures we observe an unconventional drag resistance peak near the Dirac point due to the correlated inter-layer charge puddles, which decreases monotonically with temperature (∼T⁻²) but increases rapidly with the magnetic field (∼B²). These anomalous responses together with the mismatched thermal conductivities of graphene and NWs establish the energy drag as the responsible mechanism of Coulomb drag in MLG-NW devices. In contrast, for bilayer graphene (BLG)-NW devices the drag voltage reverses sign across the Dirac Point, consistent with momentum drag but remains almost constant with magnetic field and temperature. These Coulomb drag measurements in 2D-1D systems, hitherto not reported before, will pave the future realization of correlated condensate states in novel systems.

10:00AM F53.00011: Gate-defined Quantum Confinement in few-layer Black Phosphorus Transistor*  
JIAWEI YANG (Presenter), SHI CHE, Ohio State Univ - Columbus, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, SEONGPHIL MOON, DMITRY SMIRNOV, national high magnetic field laboratory, MARC W BOCKRATH, RUOYU CHEN, CHUN NING LAU, Ohio State Univ - Columbus — Black phosphorus is a novel two-dimensional(2D) semiconductor which has attracted considerable research interest due to its tunable band gap and high electron mobility. Here we demonstrate quantum confinement defined by split gate in devices based on few-layer black phosphorus. The tunability of split gate can be illustrated by the fact that a device can be tuned off by split gate alone. Quantized conductance is observed when the width of the quantum point contact is varied. In quantum Hall regime, p-p'-p junction formed by tuning split gate are studied. The work opens the door for using black phosphorus as platform for electronic and optoelectronic applications.

Ultrafast currents in the monolayer of transition metal dichalcogenides

SEYYEDEH AZAR OLIAEI MOTLAGH (Presenter), VADYM APALKOV, MARK I STOCKMAN, Georgia State University — We theoretically predict that in a monolayer of the transition metal dichalcogenide (TMDCs), an applied ultrafast intense optical pulse with the polarization perpendicular to the TMDC's axis of symmetry induces two types of currents: a trivial current, which flows in the direction of the applied pulse and a nontrivial current, which flows in the direction perpendicular to the polarization of the pulse. The applied pulse has a linear polarization with a high amplitude of several Volt per Angstrom and the duration of a few femtoseconds. Our results show that the ultrafast field-driven currents with asymmetric profiles transfer the electrons asymmetrically, which causes the monolayer of TMDC to become electrically polarized. The induced nontrivial current and the net electrical polarization are due to Berry curvature, which is nonzero near the K and K' valleys [1].

On the nature of carrier states around the fermi level at the LAO/STO interface

LIVIU CHIONCEL, TOBIAS STROBL (Presenter), Chair for Theoretical Physics III, Augsburg University, PATRICK SAILER, Chair for Experimental Physics VI, Augsburg University, DANIEL BRAAK, Max Planck Institute for Solid State Research, Stuttgart, THILO KOPP, Chair for Experimental Physics VI, Augsburg University — We propose a minimal tight-binding one-band model for the interface layer of LAO/STO consisting of “effective” carriers (of Ti-dxy character) in random magnetic fields. These fields result from the hybridization of Ti-d(e_g)-bands and oxygen vacancies at the LAO/STO interface and can be seen as local moments (i.e. “effective impurities”) located at the Ti-site. Both the effects of a nonmagnetic on-site potential and the exchange interactions (Zeeman like) between carrier and magnetic impurities are taken into account. We apply the coherent potential approximation in studying this system.

TRR80: From Electronic Correlations to Functionality, Transregional research center of the German Research Foundation (DFG)
Electronic states and transport in graphene-TMD heterostructures

NOHORA HERNÁNDEZ CEPEDA, LILIA MEZA-MONTES (Presenter), Benemerita Universidad Autonoma de Puebla, SERGIO E ULLOA, Department of Physics and Astronomy, Ohio University — The advent of graphene and other monolayer 2D materials has opened the possibility to combine them in stacks that show interesting effects. We study here one interesting example, as the proximity of graphene and transition-metal dichalcogenides (TMD) heterostructures (G-TMD) results on unusual electronic states and transport properties. We employ an effective Hamiltonian that describes the broken inversion symmetry in graphene due to the proximity of the TMD but preserves temporal inversion [1]. The latter symmetry can be broken when an external magnetic field is applied, generating gaps in the band structure and consequent changes in electronic states that we study as function of field direction and magnitude for different TMD systems. We focus on the competition with spin-orbit effects. We also present results on transport properties, calculating the spin-dependent transmission and reflection coefficients of carriers propagating on a graphene sheet decorated with TMD ribbons on top.

Experimental Quantum Transport Strain Engineering in Graphene

GUOQING WEI (Presenter), ANDREW C MCRAE, LINXIANG HUANG, ALEXANDRE CHAMPAGNE, Department of Physics, Concordia University, Montreal, Canada — We measure ballistic charge conductivity in strained suspended graphene and observe the theoretically predicted [1] strain-induced scalar and vector potentials. To do so, we built an experimental platform for quantum transport strain engineering in 2D materials. This instrumentation permits low temperature (0.3 K- 70 K) transport, 0T - 9T magnetic fields, and a tunable uniaxial strain (up to 3%) which is independent from the gate-tunable charge density. We show slippage-free clamping of high aspect-ratio graphene crystals where atomically ordered edges are unnecessary for quantitative straintronics. We study in detail transport in a graphene channel whose length is 90 nm and width is 600nm. we observe that both the channel and contacts are ballistic. By applying strain, we find the strain-induced scalar potential which shifts the low energy band structure downward by up to 30 meV. We also clearly observe the effect of a gauge vector potential which reversibly suppresses the conductance by up to 13.6%. We next aim to demonstrate total suppression of conductivity [1] and explore straintronics in other 2D materials.

8:00AM F54.00001: Chalker-Coddington network model as a Floquet topological insulator*

VICTOR GURARIE (Presenter), Department of Physics and Center for Theory of Quantum Matter, University of Colorado, Boulder, ANDREW POTTER, Department of Physics, University of Texas at Austin — We re-examine the Chalker-Coddington network model, which was originally introduced to model integer quantum Hall plateau transitions. We point out that the dynamics of this model actually describe a periodically-driven (Floquet) system whose bands have vanishing Chern number throughout the phase diagram. Instead, the topological phase of the network model arises from a non-trivial dynamical Floquet invariant, i.e. the network model describes transitions between trivial and chiral Floquet phases of a distinct topological class from the integer quantum Hall effect. In view of this observation, we re-evaluate the standard arguments given in the past that the quantum Hall plateau transition and the transition in the Chalker-Coddington network model belong to the same universality class.

8:12AM F54.00002: Quantum Hall Effect in Quasi-One-Dimensional Weak Topological Insulator*

TIANYI XU (Presenter), PATRICK CHEUNG, University of Texas at Dallas, FENGCHENG WU, University of Maryland, College Park, FAN ZHANG, University of Texas at Dallas — Prototypical weak topological insulators (WTI) have been theoretically predicted to be realized in quasi-one-dimensional materials Bi₄X₄ (X = Br, I) [PRL 116, 066801 (2016)] and then experimentally confirmed in ARPES [Nature (London) 566, 518 (2019)]. The unique surface states of such a WTI have two entangled Dirac cones with strong anisotropy. We study theoretically the integer quantum Hall effect of such WTI surface states and show the important roles played by the special geometry, symmetry, topology, and their interplay in Bi₄X₄. We also predict prominent signatures in transport experiments.

*This theoretical work at UTD is supported by Natural Science Foundation under Grant No. DMR-1921581 through the DMREF program and Army Research Office under Grant No. W911NF-18-1-0416.
Non-interacting and interacting Graphene in a strong uniform magnetic field

ANKUR DAS (Presenter), RIBHU KAUL, GANPATHY MURTHY, Univ of Kentucky — We study monolayer graphene in a uniform magnetic field in the absence and presence of interactions. In the non-interacting limit for p/q flux quanta per unit cell, the central two bands have 2q Dirac points in the Brillouin zone in the nearest-neighbor model. These touchings and their locations are guaranteed by chiral symmetry and the lattice symmetries of the honeycomb structure. If we add a staggered potential and a next nearest neighbor hopping we find their competition leads to a topological phase transition. We also study the stability of the Dirac touchings to one-body perturbations that explicitly lowers the symmetry.

In the interacting case, we study the phases in the strong magnetic field limit. We consider on-site Hubbard and nearest-neighbor Heisenberg interactions. In the continuum limit, the theory has been studied before [1]. It has been found that there are four competing phases namely, ferromagnetic, antiferromagnetic, charge density wave, and Kekulé distorted phases. We find phase diagrams for q=3,4,5,6,9,12 where some of the phases found in the continuum limit are co-existent in the lattice limit with some phases not present in the continuum limit.

Quantum Hall Effect in Chirality-induced Weyl Semiconductor n-type Tellurene

GANG QIU (Presenter), CHANG NIU, YIXIU WANG, MENGWEI SI, WENZHUO WU, PEIDE (PETER) YE, Purdue Univ — Very recently a new mechanism of generating Weyl nodes were proposed in chiral crystals with strong spin-orbit coupling, which, in sharp contrast to conventional band-inversion-induced Weyl semimetals, can exist in semiconductor systems. Tellurium (Te) is predicted to have these Weyl nodes located at the edge of the conduction band, originated from its DNA-like chiral chain crystal structure. However Te is naturally p-type doped and its conduction band has rarely been studied through transport measurement. In this work we report the first quantum Hall experiment in ALD doped n-type 2D tellurium (dubbed as tellurene) samples with mobility 6,000 cm²/Vs. The chirality-induced Weyl nodes give rise to radial spin texture, and topologically non-trivial π Berry phase was detected in quantum Hall sequences. Additionally, the doping profile forms a wide quantum well with symmetric-antisymmetric energy states leading to an approximate SU(8) isospin symmetry. Our work expands the spectrum of Weyl matters into semiconductor regime for the first time.

*A portion of this work was performed at the NHMFL supported by NSF Cooperative Agreement No. DMR-1644779 and the State of Florida. The synthesis of 2D Te materials is supported by the National Science Foundation under Grant CMMI-1762698.
8:48AM F54.00005: Chiral quasiparticle tunneling between quantum Hall edges in proximity with a superconductor*  
IVAN BORZENETS (Presenter), City Univ of Hong Kong, MING-TSO WEI, ANNE M DRAELOS, ANDREW SEREDINSKI, CHUNG-TING KE, Duke University, KENJI WATANABE, TAKASHI TANIGUCHI, NIMS, MICHIHISA YAMAMOTO, SEIGO TARUCHA, RIKEN, FRANCOIS AMET, Appalachian State, GLEB FINKELSTEIN, Duke University — We study a two-terminal graphene Josephson junction with contacts shaped to form a narrow constriction, less than 100 nm in length. The contacts are made from type-II superconducting contacts and able to withstand magnetic fields high enough to reach the quantum Hall regime in graphene. In this regime, the device conductance is determined by edge states, plus the contribution from the constricted region. In particular, the constriction area can support supercurrents up to fields of ∼2.5 T. Additionally, enhanced conductance is observed through a wide range of magnetic fields and gate voltages. This additional conductance and the appearance of supercurrent is attributed to the tunneling between counterpropagating quantum Hall edge states along opposite superconducting contacts.

9:00AM F54.00006: Hall and dissipative viscosity and conductivity in a disordered 2D electron gas  
IGOR BURMISTROV (Presenter), Landau ITP - Chernogolovka, MOSHE GOLDSTEIN, MORDECAI KOT, Raymond and Beverly Sackler School of Physics and Astronomy, Tel Aviv University, VLADISLAV KURILOVICH, PAVEL KURILOVICH, Department of Physics, Yale University — Hydrodynamic charge transport is at the center of recent research efforts. Of particular interest is the nondissipative Hall viscosity, which conveys topological information in clean gapped systems. The prevalence of disorder in the real world calls for a study of its effect on viscosity, as well as on its relation with the nonlocal conductivity, the main venue to its experimental measurement. Here we address this question for disordered noninteracting 2D electrons. Analytically, we employ the self-consistent Born approximation, accounting for the modification of the single-particle density of states and the elastic transport time by the Landau quantization. Our results interpolate smoothly between the limiting cases of weak (strong) magnetic field and strong (weak) disorder. In the regime of weak magnetic field we describe the quantum (Shubnikov-de Haas type) oscillations of the viscosity, nonlocal conductivity, and Wen-Zee response. For strong magnetic fields we characterize the effects of the disorder-induced broadening of the Landau levels on the transport coefficients. This is supplemented by numerical calculations for a few filled Landau levels. Our results show that the Hall viscosity and its relation with conductivity are surprisingly robust to disorder.
9:12AM F54.00007: Geometric entanglement in integer quantum Hall states*  LUCIE FOURNIER (Presenter), WILLIAM WITCZAK-KREMPA, Universite de Montreal — We study the structure of entanglement in integer quantum Hall states using the entanglement entropy (EE) as well as the reduced density matrix, through its spectrum and eigenstates. We focus on an important class of spatial regions that have a sharp corner, which leads to an angle-dependent contribution to the EE. We unravel surprising relations by comparing this corner term at different fillings. We further find that the corner term, when properly normalized, has nearly the same angle dependence as conformal theories in 2 spatial dimensions. We also reveal that the low-lying entanglement spectrum and corresponding eigenfunctions describe edge excitations localized at the corner. Finally, we present an outlook for fractional quantum Hall states.

9:24AM F54.00008: Strong-disorder renormalization group approach to the integer quantum Hall effect  JOÃO GETELINA (Presenter), Sao Carlos Institute of Physics at the University of Sao Paulo; Missouri University of Science and Technology, MARTIN PUSCHMANN, Missouri University of Science and Technology, JOSE A HOYOS, Sao Carlos Institute of Physics at the University of Sao Paulo, THOMAS VOJTA, Missouri University of Science and Technology — The critical behavior of the integer quantum Hall transition has recently reattracted considerable attention [1]. We propose an alternative numerical approach, namely a modified strong-disorder renormalization group (SDRG) method, in order to investigate this transition. The SDRG method is a recursive decimation process which is known to yield exact results for electronic tight-binding models, provided one keeps all links generated under renormalization. In practical applications, the number of kept links is limited. Nonetheless, in a recent study of the Anderson localization transition, it has been shown that one can get reasonable results for the critical exponents by keeping only a relatively small maximum number of links per site [2]. We generalize this method to the integer quantum Hall problem and apply it to both square lattice and long strip geometries.

9:36AM F54.00009: Non-local induced pairing in chiral edge states* ANDREAS MICHELS (Presenter), Physics and Materials Research Science Unit, University of Luxembourg, PATRIK RECHER, Department of Mathematical Physics, TU Braunschweig, BERND H. BRAUNECKER, School of Physics and Astronomy, University of St. Andrews, THOMAS SCHMIDT, Physics and Materials Research Science Unit, University of Luxembourg — A superconductor in contact with a quantum Hall material will induce fundamentally non-local superconducting correlations in the quantum Hall edge state through the proximity effect. Such correlations are often put into models by hand in local approximations, but by building a model without assumed locality we are able predict the strength and non-local spatio-temporal behaviour of the correlation. Accurately modelling this correlation allows us to treat geometries of experimental interest and predict the behavior of interesting effects such as crossed Andreev reflection. This is relevant for several recent experiments, and the treated hybridized state has been proposed as part of a system hosting non-Abelian anyonic zero modes.

9:48AM F54.00010: Reconstruction near the interface of a $\nu=4$ and $\nu=3$ QH systems* AMARTYA SAHA (Presenter), Univ of Kentucky, SUMAN DE, Harish-Chandra research Institute, GANPATHY MURTHY, Univ of Kentucky, SUMATHI RAO, Harish-Chandra research Institute, YUVAL GEFEN, Weizmann Institute of Science — We study the Hartree-Fock ground state near the interface between the $\nu=4$ and $\nu=3$ quantum Hall systems. In this problem we have two tuning parameters, $w$ which is the width of interface in units of $l$ (magnetic length), and $E_c$ which is the strength of coulomb interaction in units of the cyclotron energy. In the bulk, for $2.52 < E_c < 2.94$, the $\nu=3$ state is fully polarised but $\nu=4$ state is a singlet. We have found that in this regime there are two edge phases. Phase 1 has 3 chiral modes, 2 downstream and 1 upstream. In this phase spin is a good quantum number. In Phase 2 we only found 1 chiral mode which is downstream. This phase has a spin rotation and can have a pair of counter propagating neutral modes. We use the time dependent Hartree-Fock method to calculate the collective excitations of these phases.

10:00AM F54.00011: Spin-1 Photonic Skyrmion in Viscous Quantum Hall Fluids* TODD VAN MECHELEN (Presenter), ZUBIN JACOB, Purdue Univ — We present the fundamental model of a topological electromagnetic phase of matter: viscous Maxwell-Chern-Simons theory. We demonstrate that this is the minimal (exactly solvable) gauge theory with a nontrivial photonic Chern number. The interplay of symmetry and topology is also captured in the Chern number, which is determined by the spin-1 representations of a photonic skyrmion at high-symmetry points in the Brillouin zone. Physically, our predicted electromagnetic phases are connected to a dynamical photonic mass in a viscous quantum Hall fluid. The electromagnetic phase is topologically nontrivial when the Hall viscosity inhibits the total bulk Hall response. Our work bridges the gap between electromagnetic and condensed matter topological physics while also demonstrating the central role of spin-1 quantization in nontrivial photonic phases.

10:12AM F54.00012: Excited quantum Hall effect: enantiomorphic flat bands in a Yin-Yang Kagome lattice* YINONG ZHOU (Presenter), GURJYOT SETHI, HANG LIU, University of Utah, ZHENGFEI WANG, University of Science and Technology of China, FENG LIU, University of Utah — Quantum Hall effect (QHE) is one of the most fruitful research topics in condensed-matter physics. Ordinarily, the QHE manifests in a ground state with time-reversal symmetry broken by magnetization to carry a quantized chiral edge conductivity around a two-dimensional insulating bulk. We propose a theoretical concept and model of non-equilibrium excited-state QHE (EQHE) without intrinsic magnetization. It arises from circularly polarized photoexcitation between two enantiomorphic flat bands of opposite chirality, each supporting originally a helical topological insulating state hosted in a Yin-Yang Kagome lattice. The chirality of its edge state can be reversed by the handedness of light, instead of the direction of magnetization as in the conventional quantum (anomalous) Hall effect, offering a simple switching mechanism for quantum devices. Implications and realization of EQHE in real materials are discussed.

10:24AM F54.00013: ferromagnetic transition in chiral metal TONGTONG LIU (Presenter), ZHEN BI, SUNGJOON HONG, LIANG FU, Massachusetts Institute of Technology MIT — This letter studies a spinful 1D chiral electron model with contact interaction and nonlinear dispersion, where an itinerant ferromagnetic phase transition happens at repulsive interaction and an Amperean pairing at attractive interaction, the two phases are symmetrical and connected by a particle-hole transformation. We use bosonization and relate it with the fermion model to study the phase transition criticality and find the spin and charge modes have different dynamical exponent, which leads to a fractional-power time correlation, unlike the Luttinger liquid theory. We also find a similar transition in the quantum Hall edge states, the nonlinear dispersion is replaced with the presence of interaction form factor after projecting to the Landau levels.
10:36AM F54.00014: van der Waals Heterostructures of 3D Topological Insulators and 2D Magnetic Materials* SHUWAN LIU (Presenter), SU KONG CHONG, TAYLOR D. SPARKS, VIKRAM V DESHPANDE, University of Utah — Three dimensional (3D) topological insulator (TI) based van der Waals heterostructures form an excellent platform to study the proximity effect between a TI surface and another layered material, such as a two-dimensional (2D) ferromagnet. Previously we have observed both massless relativistic Dirac fermions and massive (gapped) Dirac fermions in this way for the topological surface state of BiSbTeSe$_2$\textsuperscript{1} and have reported quantum Hall data for these surfaces. However, typical ferromagnets get oxidized easily during the fabrication process. Thus, the induced magnetization in the TI interface is not clean under ambient conditions. To minimize the influence of oxidation, we explore this fabrication inside a glovebox. We will report the performance of such TI based devices in comparison to those built-in ambient conditions and further study the proximity effect in TI-based van der Waals heterostructures.

F54.00015: Phase transition and anomalous scaling in the quantum Hall transport of topological-insulator Sn-Bi$_{1.1}$Sb$_{0.9}$Te$_2$S devices* FAJI XIE (Presenter), SHUAI ZHANG, FENGQI SONG, Nanjing University — The scaling physics of quantum Hall transport in optimized topological insulators with a plateau precision of $\sim$1/1000 e$^2$/h is considered. Two exponential scaling regimes are observed in temperature-dependent transport dissipation, one of which accords with thermal-activation behavior with a gap of 2.8 meV ($>$20 K), the other being attributed to variable-range hopping (1–20 K). Magnetic-field-driven plateau-to-plateau transition gives scaling relations of $(dR_{xy}/dB)_{\text{max}} \propto T^{-\kappa}$ and $\Delta B^{-1} \propto T^{-\kappa}$ with a consistent exponent of $\kappa \sim 0.2$, which is half the universal value for a conventional two-dimensional electron gas. This is evidence of percolation assisted by quantum tunneling and reveals the dominance of electron-electron interaction of the topological surface states.

Session F55 DCMP: Dirac and Weyl Semimetals: Theory II Mile High Ballroom 2B
8:00AM F55.00001: Non-local annihilation mechanism in momentum space for correlated Weyl fermions.* GIORGIO SANGIOVANNI (Presenter), Universitaet Wuerzburg, Institut fuer Theoretische Physik und Astrophysik and Wuerzburg-Dresden Cluster of Excellence ct.qmat, ADRIANO AMARICCI, LORENZO CRIPPA, Scuola Internazionale Superiore di Studi Avanzati (SISSA), NIKLAS WAGNER, Universitaet Wuerzburg, Institut fuer Theoretische Physik und Astrophysik and Wuerzburg-Dresden Cluster of Excellence ct.qmat, JAN BUDICH, Institute of Theoretical Physics, Technische Universitaet Dresden, MASSIMO CAPONE, Scuola Internazionale Superiore di Studi Avanzati (SISSA) — We discuss the effects of interaction in Weyl semimetals with broken time-reversal symmetry. The spin degeneracy of the gapless Dirac point at the topological quantum phase transition is resolved resulting in two gapless Weyl nodes separated in momentum space. For free fermions, the topological transition requires the two Weyl nodes to annihilate continuously in momentum space. Yet, we show that in presence of a strong local Coulomb repulsion this paradigm breaks down, opening a non-local annihilation channel for the Weyl cones.

8:12AM F55.00002: Quantum Lifshitz criticality of topological semimetals* SHOUVIK SUR (Presenter), ALEXANDER TYNER, PALLAB GOSWAMI, Northwestern University — In the absence of particle-hole symmetry, all clean topological semimetals can be realized in two thermodynamically distinct forms: a power-law, incompressible phase and a compressible phase, respectively possessing zero and constant density of states at the band touching energy. Therefore, the density of states can serve as an order parameter for describing quantum Lifshitz transitions between two thermodynamically distinct but topologically equivalent states of matter. We address the nature of such quantum Lifshitz transitions for different topological semimetals, and show how they can strongly influence thermodynamic, spectroscopic, and transport properties of many quantum materials.

*NSF DMR-1720319
**8:24AM F55.00003: Intrinsic Plasmon damping in Dirac-Fermi liquids**  
PRACHI SHARMA (Presenter), DMITRII MASLOV, University of Florida — A Dirac-Fermi liquid (DFL) — a doped system with Dirac spectrum — is a special and important subclass of non-Galilean-invariant Fermi liquids (FLs), which includes, e.g., monolayer graphene and surface states of three-dimensional topological insulators. The lack of Galilean invariance leads to some interesting features not encountered in conventional Fermi liquids. Namely, the dissipative part of the conductivity of a DFL stays finite at $q \to 0$, whereas for a Galilean-invariant FL it vanishes as $q^2$. We explore the consequences of this fundamental difference for the intrinsic damping of plasmons in DFL. Charge density fluctuation leads to a collective mode, plasmon, in a two-dimensional (2D) system with $q^{1/2}$ dispersion. The imaginary part of charge susceptibility, $\chi''(q, \omega)$, is directly related to the damping rate of the plasmon mode. We obtain the explicit form of $\chi''(q, \omega)$ for DFL, by going beyond the random-phase approximation. We calculate the self-energy, Maki-Thompson, and Aslamazov-Larkin diagrams for a dynamically screened Coulomb potential and find that $\chi''(q, \omega)$ scales as $q^2 \omega$ and the damping rate scales as $q^2$. We show that the same result follows from the Einstein relation between the conductivity and charge susceptibility.

**8:36AM F55.00004: Internodal tunnelling and magnetotransport in Weyl semimetals**  
SERGEY SYZRANOV (Presenter), GRIGORY BEDNIK, University of California, Santa Cruz, KONSTANTIN TIKHONOV, Landau Institute for Theoretical Physics, Karlsruhe Institute of Tehcnology, Skolkovo Institute of Science and Technology — Internodal dynamics of quasiparticles in Weyl semimetals manifests itself in hydrodynamic, transport and thermodynamic phenomena and is essential for potential valleytronic applications of these systems. Charge transfer between the nodes in a Weyl semimetal is often considered as an inelastic process, with the charge carriers quickly thermalising at each node. In an external magnetic field, however, coherent quasiparticle tunnelling between the nodes may lead to a significant modification of the quasiparticle dispersion in a clean Weyl semimetal for certain directions of the magnetic field. In particular, it results in the opening of a gap in the quasiparticle dispersion, whose magnitude depends exponentially on the magnetic field. We study the interplay of such tunnelling with magnetotransport in a Weyl semimetal. We compute microscopically the longitudinal resistivity of a disordered Weyl semimetal with two nodes in a strong magnetic field and demonstrate that it has a strong angular dependence $\rho(\eta) = C_1 + C_2 \cos^2 \eta$, where $\eta$ is the angle between the field and the line connecting the nodes. The first term is determined by the coherent internodal coupling and depends exponentially on the magnetic field, while the second term is independent of this coupling.
8:48AM F55.00005: Low-field anomalous Hall effect in nonmagnetic metals by Wannier interpolation. STEPAN TSIRKIN (Presenter), Department of Physics, University of Zurich, IVO SOUZA, Universidad del País Vasco, San Sebastián — In ferromagnets, the Bloch states acquire a Berry curvature that produces a Hall effect at $B = 0$: the anomalous Hall effect (AHE). In nonmagnetic metals the Hall effect only appears at linear order in $B$. Interestingly, the low-field Hall conductivity of nonmagnetic metals has an anomalous (Berry-curvature) contribution in addition to the ordinary (Lorentz-force) one. In noncentrosymmetric crystals it goes as $\sigma_{\text{AHE}} \propto \int d^3k \Omega_k (m_k \cdot B) f_0'$, where $\Omega_k$ and $m_k$ are the Berry curvature and intrinsic magnetic moment (spin plus orbital) imparted on the Bloch states by the broken inversion symmetry; since $\Omega_k$ and $m_k$ are both odd under time reversal, $k$ and $-k$ contribute equal amounts to $\sigma_{\text{AHE}}$. In centrosymmetric crystals the bands are Kramers degenerate, and the expression for $\sigma_{\text{AHE}}$ involves the trace of the product of $2 \times 2$ matrices describing the Berry curvature and magnetic moment of the degenerate states; in this case $\text{Tr} \Omega_k = \text{Tr} m_k = 0$, but $\text{Tr}(\Omega_k m_k) = \text{Tr}(\Omega_{-k} m_{-k}) \neq 0$. Working in this non-Abelian setting, we develop a Wannier-interpolation scheme to calculate the low-field anomalous Hall conductivity from first principles. As a by-product, we obtain the anomalous $g$ factors of the Bloch states. The low-field AHE is present in all metals, but is more pronounced in Weyl and Dirac semimetals.

9:00AM F55.00006: Ultrafast topological phenomena in Weyl semimetals* FATEMEH NEMATOLLAHI (Presenter), JHIH-SHENG WU, VADYM APALKOV, MARK I STOCKMAN, Georgia State University — For Weyl semimetals, we predict that an intense ultrafast (single-oscillation) circularly polarized optical pulse can induce a large population of the conduction band. The response of Weyl points to an ultrafast laser field is different and so the conduction population is highly textured which we call it topological resonance. The topological resonance is due to the Bloch motion of electrons in the reciprocal space where electron population textures are formed due to non-Abelian Berry curvature.

9:12AM F55.00007: Nodal Chain Semimetal in Geometric Frustrated Acoustic metamaterial*

MENG XIAO (Presenter), Wuhan Univ, XIAO-QI SUN, Physics, Stanford university, SHANHUI FAN, Stanford University — Geometrically frustrated systems and topological semimetals have both attracted much interest and been studied in various systems in recent years. Here we study the interplay between these two systems. We show that a Weyl point can be extended to a chain of degeneracy (a nodal chain) with nonzero charge of Berry flux through geometrical frustration. We propose to realize such a charged nodal chain in an acoustic metamaterial, based on both tight-binding and full-wave numerical simulations. Moreover, we observe a fan-like surface state spectrum, whose dispersion is controlled by the bulk band properties. Our work points to a new class of band degeneracy that carries non-zero Berry flux. The resulting topological metamaterial may be useful for controlling the flow of sound and light.

*This work is supported by a Vannevar Bush Faculty Fellowship from the U. S. Department of Defense (Grant No. N00014-17-1-3030), and by the U. S. National Science Foundation (Grant No. CBET-1641069). M. X. is supported by the funding (grant no.11904264) and the startup funding of Wuhan University.

9:24AM F55.00008: Quantum distance and anomalous Landau levels of flat bands  JUN-WON RHIM (Presenter), BOHM-JUNG YANG, Seoul Natl Univ — Semiclassical quantization of electronic states under magnetic field, advocated by Onsager, can successfully describe not only the Landau level spectrum but also the geometric responses under magnetic field in metals. Even in graphene with relativistic energy dispersion, for instance, Onsager’s rule correctly described the π-Berry phase as well as the unusual Landau level spectrum of Dirac particles. Here we show that, however, the semiclassical quantization rule completely breaks down for a class of dispersionless flat bands, dubbed the singular flat bands. The singular flat band has a band crossing with another dispersive band enforced by band flatness. In contrast to the conventional isolated flat band which does not respond to external magnetic field, the singular flat band shows anomalous Landau level structures and magnetic responses. We discuss the novel quantum geometric interpretations of them regarding the quantum distance, and how to measure them experimentally.
Superconductivity in interacting Weyl models: A combined auxiliary-field quantum Monte Carlo and mean-field study*  

PETER ROSENBERG (Presenter), NIRAJ ARYAL, EFSTRATIOS MANOUSAKIS, Natl High Magnetic Field Lab — The discovery of superconducting Weyl semimetals has sparked an intense effort to understand the connection between topology and correlations in these materials, specifically, the pairing behavior of emergent Weyl fermions. Here we study a simple 2D Weyl model with attractive interactions using a combination of numerically exact auxiliary-field quantum Monte Carlo calculations and mean-field theory [1]. We focus on the rich pairing behavior that emerges from the interplay of the spin and sublattice degrees of freedom, as well as the bond-density order. Finally, we present preliminary results on a 3D extension of the model, with direct relevance to the case of MoTe$_2$. These high-accuracy results are an important step towards a many-body description of strongly-correlated Weyl materials and topological superconductors.

*This work was supported in part by the U.S. National High Magnetic Field Laboratory, which is funded by NSF DMR-1157490 and the State of Florida.

The optical conductivity of strongly interacting Dirac fermions: a bosonization approach to the Kadanoff-Baym self-consistent resummation  

SEBASTIAN MANTILLA (Presenter), INTI SODEMANN, Max Planck Institute for the Physics of Complex Systems — The optical conductivity of 2D Dirac fermions at low energies is controlled by fundamental constants of nature $\sigma_0 = e^2/16 \hbar$. However, Coulomb interactions produce a non-trivial dependence of the conductivity with the frequency. We use a bosonization approach to implement exactly a self-consistent Kadanoff-Baym resummation of the electron-hole propagator by mapping the momentum space lattice onto a Heisenberg-type model of interacting spins and employ this approach to determine the frequency dependence of the optical conductivity for Coulomb repulsions. We recover the perturbative renormalization group results at small coupling and extend its predictions to strong coupling. We discuss the relevance of our results to Dirac materials such as graphene and 3D topological insulator surface states.
10:00AM F55.00011: SU(3) fermions in a three-band graphene-like model*  SUMIRAN PUJARI (Presenter), Department of Physics, Indian Institute of Technology Bombay, ANKUR DAS, Univ of Kentucky — Two-dimensional graphene is fascinating because of its unique electronic properties. From a fundamental perspective, one among them is the geometric phase structure near the Dirac points in the Brillouin zone, owing to the SU(2) nature of the Dirac cone wave functions. We ask if there are geometric phase structures in two dimensions that go beyond that of a Dirac cone. Here we write down a family of three-band continuum models of noninteracting fermions that have more intricate geometric phase structures. This is connected to the SU(3) nature of the wave functions near threefold degeneracies. We also give a tight-binding free fermion model on a two-dimensional graphene-like lattice where the threefold degeneracies are realized at fine-tuned points. Away from them, we obtain new “three-band” Dirac cone structures with associated nonstandard Landau level quantization, whose organization is strongly affected by the non-SU(2) or beyond-Dirac geometric phase structure of the fine-tuned points.

10:12AM F55.00012: Topological Semimetals with Butterfly-like Four-Point Intersecting Ellipses*  XIAOTING ZHOU (Presenter), HUGO ARAMBERRI, Department of Physics and Astronomy, California State University, Northridge, CHENG-YI HUANG, Institute of Physics, Academia Sinica, Taipei, Taiwan, MAIA G VERGNIORY, Donostia International Physics Center, Donostia-San Sebastian, Spain, HSIN LIO, Institute of Physics, Academia Sinica, Taipei, Taiwan, NICHOLAS KIOUSSIS, Department of Physics and Astronomy, California State University, Northridge — Recent years, the exotic properties of topological semimetals have garnered great attention and efforts in seeking for new topological phases and material realization. In this work, we introduce a new type of nodal line, the butterfly-like four-point-intersecting-ellipses (FPIE) residing in a plane. We identify the criteria for the existence of the FPIE in a time reversal invariant spinless fermion system with negligible spin-orbital coupling (SOC). In addition we demonstrate that its emergence is possible in 7 out of 230 space groups, and identify the locations it would emerge in the Brillouin zone (BZ). Using first-principles band structure calculations, we predict a family of compounds as candidates hosting the FPIE in the Fermi surface (FS) with vanishing SOC.

Unconventional Superconductivity and Mott Transition in a Sign-Free Electronic Model*

XIAO YAN XU (Presenter), TARUN GROVER, Department of Physics, University of California at San Diego — It is widely believed that repulsive on-site interactions between electrons can lead to unconventional superconductivity. Further, one expects that proximity of an unconventional superconductor to a Mott transition can lead to a quantum spin-liquid ala resonating valence bond (RVB) picture. Motivated by such folklore, here we construct a sign-problem free model that has unconventional f-wave superconductivity, and a proximate Mott transition to a Neel ordered phase. We present preliminary results on the nature of transition between these two phases, and potential spin-liquid phases in its vicinity. We also show using field-theoretic methods that a direct deconfined quantum critical point is allowed between the superconductor and the Neel phase.

Cyclotron orbit knot and tunable-field quantum Hall effect*

YI ZHANG (Presenter), International Center for Quantum Materials, Peking University — The Bohr-Sommerfeld quantization of the cyclotron orbit in a magnetic field gives rise to discrete Landau levels and a series of fascinating quantum Hall phenomena. Here we consider topologically nontrivial physics from a distinct origin, where the cyclotron orbits take nontrivial knotting structure. We present a scenario of a Weyl semimetal slab, where the Fermi arcs on the opposing surfaces can cross without interfering with each other and form a knot together with the bulk chiral Landau levels. We provide a microscopic lattice model with cyclotron orbits of trefoil-knot geometry and study the corresponding quantum oscillations. Interestingly, unlike the conventional ring-shaped cyclotron orbit, a trefoil knot is self-threading, allowing the magnetic field line along the cyclotron orbit to contribute to the overall Berry phase and therefore altering the external magnetic field for each quantization level. The cyclotron orbit knot offers an arena of the nontrivial knot theory in three spatial dimensions and its subsequent physical consequences.

Session F56 DCMP: Cuprate and Iron Superconductor Normal State Properties Mile High Ballroom 2C - Ming Yi, Rice Univ
8:00AM F56.00001: Fermi surface transformation across the pseudogap critical point in the cuprate Nd-LSCO from thermoelectric measurements  ADRIEN GOURGOUT (Presenter), CLEMENT COLLIGNON, AMIRREZA ATAEI, SVEN BADOUX, GAELE GRISSONNANCHE, MARIE-EVE BOULANGER, FRANCIS LALIBERTE, University of Sherbrooke, JIANSHI ZHOU, University of Texas, QIANLI MA, BRUCE D. GAULIN, McMaster University, NICOLAS DOIRON-LEYRAUD, LOUIS TAILLEFER, University of Sherbrooke — In cuprate superconductors, the nature of the pseudogap phase and its interplay with superconductivity are still unclear. Its onset at a doping $p^*$ is characterized by a drop in the carrier density $n$ from $n = 1+p$ above $p^*$ to $n = p$ below $p^*$ [1]. In Nd$_{0.4}$La$_{1.6-x}$Sr$_x$CuO$_4$ (Nd-LSCO), this shows up as a low-temperature upturn in the resistivity $\rho$ and Hall coefficient $R_H$ at dopings below $p^* = 0.23$ [2]. Here we present a series of thermoelectric measurements in Nd-LSCO across $p^*$, in magnetic fields large enough to suppress superconductivity. For a heat current in the CuO$_2$ planes, the Seebeck coefficient $S$ shows a large increase at low temperature below $p^*$, confirming the loss of carrier density. Application of pressure suppresses the low-$T$ upturn in $S/T$, as it did the upturn in $\rho$ and $R_H$ [3]. For a heat current perpendicular to the CuO$_2$ planes, we find that $S$ is isotropic for $p > p^*$, i.e. $S_c/T$ and $S_a/T$ are equal (and positive) in the $T=0$ limit. In sharp contrast, $S_c$ becomes negative at low temperature when $p < p^*$, revealing a profound change in the Fermi surface topology across $p^*$.

8:12AM F56.00002: Spiral magnetic order in high-$T_c$ cuprates - a ground state candidate at high magnetic fields  JOHANNES MITSCHERLING (Presenter), PIETRO MARIA BONETTI, DEMETRIO VILARDI, WALTER METZNER, Max Planck Institute for Solid State Research, Stuttgart, Germany — The normal state beneath the superconducting dome determines the fluctuations that govern the anomalous properties of cuprate superconductors in a wide range of their phase diagram. Recent experiments at very high magnetic fields shed new light on the phenomenology of the high field ground state: A drastic change in the carrier density at the onset of the pseudogap observed in various cuprate compounds, thermodynamic signatures of a quantum critical point at this doping and, very recently, NMR and ultrasound experiments indicated glassy antiferromagnetic order up to the pseudogap onset.

We present incommensurate spiral magnetic order as a potential ground state candidate at high magnetic fields [1,2]. Previous theoretical work suggests that suppression of superconductivity leads to such a ground state [3]. We present quantitative results for magnetic order in the Hubbard model at strong coupling using dynamical mean-field theory [4]. We show that experimental signatures as Fermi arcs, nematicity and the drop in both the DC conductivity and Hall number can be understood within this framework.

8:24AM F56.00003: Thermodynamic evidence of quantum criticality at the pseudogap critical point of cuprate superconductors  CLÉMENT GIROD (Presenter), BASTIEN MICHON, MAUDE LE LIZAIRE, ADRIEN GOURGOUT, SVEN BADOUX, NICOLAS DOIRON-LEYRAUD, FRANCIS LALIBERTE, Universite de Sherbrooke, JOZEPH KAČMARČÍK, Slovak Academy of Sciences, SIMON VERRET, Universite de Sherbrooke, JIANSHI ZHOU, University of Texas at Austin, QIANLI MA, MIRELA DRAGOMIR, HANNAH A. DABKOWSKA, BRUCE D. GAULIN, McMaster University, SUNSENG PYON, TOMOHIRO TAKAYAMA, HIDENORI TAKAGI, University of Tokyo, GUO-QING ZHENG, Okayama University, SHIMPEI ONO, CRIEPI, CHRISTOPHE MARCENAT, Institut Néel, LOUIS TAILLEFER, Universite de Sherbrooke, THIERRY KLEIN, Institut Néel — The emergence of superconductivity in the vicinity of a magnetic quantum critical point (QCP) in heavy-fermion, iron-based, organic and electron-doped cuprate superconductors showcases the important relation between quantum criticality and pairing. In hole-doped cuprates, long-range antiferromagnetic order vanishes with doping well before superconductivity appears. Instead, it is around the critical doping p* where the enigmatic pseudogap phase ends that superconductivity exists. The fact that the electrical resistivity displays a linear temperature dependence at low temperature in all these systems, including hole-doped cuprates [1], is suggestive. Here we provide thermodynamic evidence of a QCP in hole-doped cuprates from low-temperature measurements of the specific heat in magnetic fields up to 35 T, high enough to suppress superconductivity. In LSCO, Eu-LSCO, Nd-LSCO and Bi2201, we observe an electronic specific heat that grows as $C/T \sim \log(1/T)$ at $p \sim p^*$ [2], the classic thermodynamic signature of quantum criticality.

8:36AM F56.00004: Large negative thermal Hall conductivity in cuprate Mott insulators  MARIE-EVE BOULANGER (Presenter), GAEL GRISONNANCHE, MAXIME DION, ETIENNE LEFRANCOIS, Universite de Sherbrooke, RUIXING LIANG, WALTER N HARDY, DOUGLAS A BONN, University of British Colombia, JIANSHI ZHOU, The University of Texas at Austin, LOUIS TAILLEFER, Universite de Sherbrooke — A large negative thermal Hall signal $k_{xy}$ has recently been observed to appear in the pseudogap phase of cuprates [1]. This signal persists to zero doping, in the antiferromagnetic Mott insulator La$_2$CuO$_4$. While it is clearly not due to electrons, this $k_{xy}$ signal could come from magnons, or phonons — or more exotic excitations. To shed light on the underlying mechanism, we measured $k_{xy}$ in two additional cuprate Mott insulators: Nd$_2$CuO$_4$ and Sr$_2$CuO$_2$Cl$_2$. We observe a large negative $k_{xy}$ signal in both materials. Because of the absence of spin canting in either of these materials without apical oxygens, and because of the absence of any change in $k_{xy}$ upon crossing different magnetic states in Nd$_2$CuO$_4$, we infer that magnons are not the heat carriers responsible for $k_{xy}$. The similarity in the temperature dependence of $k_{xy}$ and $k_{xx}$ suggests a phonon scenario. If so, the mechanism whereby the pseudogap phase confers chirality to phonons remains to be elucidated.

8:48AM F56.00005: Deep in the electron-doped cuprate pseudogap regime: a two-particle self-consistent approach with \( \text{GG}_0 \) approximation to the two-dimensional Hubbard model*  
YAN WANG (Presenter), YURI VILK, ANDRE-MARIE TREMBLAY, Universite de Sherbrooke — In cuprate high-\( T_c \) superconductors, the pseudogap (PG) manifests itself at low temperature as a gradual depletion of the density of states at the Fermi level. In electron-doped cuprates, the nonperturbative semianalytical two-particle-self-consistent (TPSC) approach naturally explains the PG as the finite-\( T \) precursor of the antiferromagnetic (AFM) bands of the ordered ground state at \( T=0 \). In contrast to Mott physics, the PG opens in two dimensions at hot spots in momentum space due to scattering off spin-fluctuations when the AFM correlation length becomes longer than the thermal de Broglie wavelength. However, TPSC eventually fails at temperatures deep in the PG regime with exponentially growing AFM correlation length. Here, we extend TPSC with the \( \text{GG}_0 \) approximation to the irreducible particle-hole polarization where one of the propagators \( \text{G} \) is self-consistently dressed by TPSC self-energy. Benchmarking with other controlled numerical methods, we demonstrate that this modified TPSC approach predicts quite accurate one-particle and two-particle properties deep in the PG regime, satisfies various sum rules and consistency relations and joins smoothly with the \( T=0 \) AFM ground state.

9:00AM F56.00006: Disorder effects on the phase diagram of electron-doped cuprates using the two-particle self-consistent approach*  
CHLOE-AMINATA GAUVIN-NDIAYE (Presenter), ANDRE-MARIE TREMBLAY, Institut Quantique, Universite de Sherbrooke — The two-particle self-consistent approach (TPSC) is a highly accurate theoretical method for electronic systems that can be described by the one-band Hubbard model in the weak to intermediate coupling regime. [1] In particular, it can successfully describe the electron-doped cuprates. One of the predictions of TPSC for these materials is that the pseudogap occurs when the antiferromagnetic spin correlation length become larger than the thermal de Broglie wave length. [1,2] This TPSC condition for the pseudogap has been confirmed experimentally in the underdoped regime. However, this analysis fails in the optimal doping regime. [3,4] In this work, we include the effect of impurities and disorder in TPSC using the impurity averaging technique. We then investigate the effect of disorder on the TPSC condition for the pseudogap and on the critical doping for the crossover temperature.

9:12AM F56.00007: Measured vs. Calculated Phonon Dispersions in the Cuprate HgBa$_2$CuO$_4$*

IRADA AHMADOVA, TYLER STERLING (Presenter), AARON SOKOLIK, ADRIAN MERRITT, University of Colorado, Boulder, DOUGLAS L ABERNATHY, Oak Ridge National Lab, MUN K. CHAN, YANG TANG, GUICHUAN YU, MARTIN GREVEN, University of Minnesota, DMITRY REZNIK, University of Colorado, Boulder — Taking the prototypical high-T$_c$ superconductor HgBa$_2$CuO$_4$ as an example, I will compare ab-initio density-functional-theory (DFT) calculations of the phonon dispersions to inelastic neutron scattering results that exhibit an anomaly in the Cu-O bond stretching branch. We have performed a series of calculations using several codes at different levels of approximation. Our results show good qualitative agreement for all codes, but only one gave a good quantitative agreement (better than 10%). All DFT calculations fail to reproduce the experimentally observed anomalous dispersion of the bond-stretching phonon branch. I will conclude my talk by mentioning other computational methods that may improve the agreement between the calculations and measurement.

9:24AM F56.00008: Nature of the pseudogap in cuprate superconductors*

YOANDRIS VIELZA DE LA CRUZ (Presenter), Department of Physics, Federal University of Pernambuco — The base of the mean-field model that describes the main physical properties of the cuprate superconductors is presented, the single-band Hubbard Hamiltonian of the Mott-states of electrons on CuO-plane. In the present work, the Hamiltonian is diagonalized on a Hartree-Fock base of collinear spins states that leaves fixed the magnetic order on the square sublattices. Adjusted the mean-field in the unit cell to a gap of $\sim$ 2 eV at half-filling and to a maximum value of pseudogap observed of $\sim$ 100 meV, an evaluation of the Hartree-Fock Mott-states in doping with holes and electrons and at the zero absolute temperature is made. It is shown that the mean-field adjust the density of the states at the Fermi level according to the experimental measure. The base of the Hartree-Fock Mott-states prove that the opening of the pseudogap in cuprate superconductors define a phase of low density of states at the Fermi level resulting from Coulomb repulsion on Cu-sites that penalizes two electrons being close to each other. It is also argued that the spontaneous breaking of rotational symmetry in the antiferromagnetic order of the Mott-states leads to the electron pair formation in cuprate superconductors.

**9:36AM F56.00009: Criticality vs material inhomogeneity: an analysis of LSCO magnetoresistance data** CHRISTIAN BOYD (Presenter), PHILIP PHILLIPS, University of Illinois at Urbana-Champaign — Recent thin-film LSCO measurements have observed, in addition to the hallmark T-linear resistivity of cuprates near optimal doping, B-linear resistivity in strong magnetic fields. We analyze existing data on this thin-film sample to demonstrate that, contrary to the high-Tc iron superconductors near optimal doping, no single scaling function of temperature and field can describe the magnetoresistance data across all measured temperatures above and below the superconducting Tc. We model the high-temperature data within a classically-disordered system of conducting patches with qualitative accuracy. Interestingly, the breakdown of this model at low temperatures when the mean free path exceeds the lengthscale of disorder happens to correspond with the experimentally observed region where the resistivity changes character to become simultaneously T,B linear.

**9:48AM F56.00010: What can Density Functional Theory tell us about Pseudogaps?** ROBERT MARKIEWICZ (Presenter), Northeastern University, YUBO ZHANG, Tulane University, CHRISTOPHER LANE, Northeastern University, JAMES FURNESS, Tulane University, MATT MATZELLE, Northeastern University, BERNARDO BARBIELLINI, LUT & Northeastern Universities, JOHN P. PERDEW, Temple University, JIANWEI SUN, Tulane University, ARUN BANSIL, Northeastern University — We have shown recently that advanced exchange-correlation functionals can enable first-principles treatment of the electronic, geometric and magnetic structure of the cuprates and other correlated materials without the need to invoke ad hoc parameters such as the Hubbard U. [1,2] Here, we focus on how in this picture the pseudogap phase in YBaCu3O7 involves a large number of competing magnetic and stripe phases with small energy differences, which can be looked upon as simple antiferromagnets with topological defects, i.e. defects consisting of stacking faults and charged antiphase boundaries or the charged stripes[3,4]. A simple thermodynamic model suggests that the pseudogap consists of fluctuating short-range ordered (SRO) phases, while the strange metal corresponds to defect unbinding. The SRO phases display nematicity and Fermi arcs. Comparisons with experiment will be discussed.

10:00AM F56.00011: Determine the spatial locality of self-energy of LiFeAs*  
MINJAE KIM (Presenter), Department of Physics and Astronomy, Rutgers University, New Brunswick, HU MIAO, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, GABRIEL KOTLIAR, Department of Physics and Astronomy, Rutgers University, New Brunswick — Understanding of the electronic correlations is crucial to explain the electronic properties, magnetism, and superconductivity of the iron-based superconductors (FeSCs). An important question is the degree of spatial locality of the electronic correlations. Local correlations is the starting point of dynamical mean-field theory (DMFT), which has been proved to be powerful in understanding spectroscopic properties of the FeSCs [1,2]. However, recent theoretical and experimental reports on one of the FeSCs, LiFeAs, suggested the importance of non local correlations[3,4]. In this presentation, we extract spatially resolved and orbital dependent electronic self-energy of LiFeAs from angle resolved photoemission spectroscopy with density functional theory as a reference frame, and discuss the level of locality in the different orbitals, with the xy orbital being more local than the xz yz. We also discuss how the level of non locality depends on energy.

*This work was supported by Grant No. NSF DMR-1733071.

10:12AM F56.00012: Quasiclassical theory of C4-symmetric magnetic order in disordered iron-based superconductors*  
MAXIM DZERO (Presenter), Kent State Univ - Kent — In some hole-doped iron-based superconductors the magnetic order emerges with underlying C4-symmetry. This magnetic order can be viewed as a state with two ordering vectors with the corresponding magnetizations M1 and M2. In my talk, I will formulate a quasi-classical theory of such a state. Specifically, I will consider a three-band model, which, apart from the magnetic interactions, includes intra- and interband disorder scattering potentials. I will develop the quasiclassical approach for such a model and show how disorder scattering rates enhance the emergence of the C4-symmetric magnetic order.

*NSF-DMR-1506547
Electronic nematicity is the spontaneous breaking of rotational symmetry in a metal, and it has been argued to potentially strengthen superconductivity. It is a key feature of iron-based high-temperature superconductors. In cuprate high-temperature superconductors, a number of experiments have revealed evidence of nematicity, but its origin remains unclear. We measured the in-plane anisotropy of the electrical resistivity $\rho(T)$ and the Seebeck coefficient $S(T)$ in a crystal of the cuprate $\text{YBa}_2\text{Cu}_3\text{O}_y$, at hole concentration $p = 0.12$. By using the same sample and contacts to measure transport along the $a$ axis and the $b$ axis of the orthorhombic crystal structure, by detwining this sample twice, such that its length was first along $a$ and then along $b$, we were able to precisely obtain the intrinsic in-plane anisotropy of these two longitudinal transport coefficients. We find no trace of any additional anisotropy in either $\rho(T)$ or $S(T)$ upon crossing below the pseudogap temperature $T^*$. A large anisotropy appears only at much lower temperature, in tandem with the emergence of charge density wave correlations. We conclude that the pseudogap phase itself is not nematic, and the nematicity in $\text{YBa}_2\text{Cu}_3\text{O}_y$ originates instead from the unidirectional charge order and its precursor correlations.

10:36AM F56.00014: Diverse unconventional density wave states in high-$T_c$ cuprates and other unconventional superconductors HIROSHI KONTANI (Presenter), KOUKI KAWAGUCHI, RINA TAZAI, YOUICHI YAMAKAWA, SEIICHIRO ONARI, Nagoya Univ — We discuss the mechanism of diverse nematic orders in various strongly correlated electron systems, by considering the interference among different fluctuations given by vertex corrections (VCs). We mainly focus on the ferro- and stripe-bond orders in cuprate superconductors and organic superconductor $\kappa$-(BEDT-TTF)$_2X$. The bond order formation is closely related to the pseudogap phenomena in these systems. We also discuss important effects on bond-order fluctuations on the superconductivity and other electronic properties. We also discuss possible time-reversal-symmetry breaking nematic order based on the Hubbard model.

F56.00015: Investigation of the Orbital Moment on the Fe Impurities in Iron-Based Superconductor SHIYU PENG (Presenter), Chinese Academy of Sciences, Institute of Physics, JIANPENG LIU, Physics, The Hong Kong University of Science and Technology, HONGMING WENG, Chinese Academy of Sciences, Institute of Physics, XI DAI, Physics, The Hong Kong University of Science and Technology — Our previous study show that the orbital exchange process induced by large orbital magnetic moment can lead to quantum anomalous vortices, which may further support robust Majorana zero-energy modes together with the topologically nontrivial surface states. In the present study, by applying LDA+Gutzwiller method we have systematically studied the value of the orbital magnetic moment as the function of the height between the Fe impurity and the surface of superconducting Fe(Te,Se). The local Coulomb Interaction between the electrons on the Fe impurities has been treated carefully by the rotational invariant Gutzwiller method with the variational parameters corresponding to the the most generic situation. Our results show the orbital contribution to the magnetic moment is always sizeable in this system and can be strongly affected by the impurity height.

Session F57 DMP: Superconductivity In Monolayers Mile High Ballroom 3A - Peide
(Peter) Ye, Purdue Univ - Tag(s): Focus

8:00AM F57.00001: Ultrafast Dynamics in Normal and CDW States of 2H-NbSe$_2^*$  
GORAN KARAPETROV (Presenter), Physics and Materials Science and Engineering, Drexel University, ANTON ANIKIN, Physics, Drexel University, RICHARD D SCHALLER, GARY P WIEDERRECHT, Center for Nanoscale Materials, Argonne National Laboratory — We have performed femtosecond pump-probe reflectivity study of the carrier and lattice dynamics using near-IR pump and white broadband probe at temperatures below and above the charge density wave transition in single crystal NbSe$_2$. The temperature dependence of the frequency of the coherent damped oscillations shows a second order softening when approaching $T_{CDW}$. This mode can be described as a combination of two acoustic phonons, one of which has Kohn anomaly in a broad range of temperatures. We extracted basic characteristics of the soft mode and its anharmonic decay. Global analysis fits from femtosecond to nanosecond scale were applied to describe the relaxation dynamics from the broadband transient reflectivity data.

8:12AM F57.00002: Two-fold anisotropic superconducting properties of few-layer NbSe$_2^*$  
BRETT HEISCHMIDT, ALEX HAMILL (Presenter), KAN-TING TSAI, DANIEL SHAFFER, XI ZHANG, RAFAEL FERNANDES, KE WANG, VLAD PRIBIAG, University of Minnesota — Transition metal dichalcogenides (TMDs) are a class of layered van der Waals materials that have recently attracted considerable interest due to a wide range of properties in the two-dimensional limit, including superconductivity, topological phases, and spin-valley-locked bands due to strong orbit coupling and inversion-symmetry breaking. Here, we present transport properties of few-layer niobium diselenide (NbSe$_2$), a TMD that exhibits signatures of an unusual Ising superconducting state as its thickness approaches the 2D limit. We perform magneto-transport experiments on high-quality few-layer NbSe$_2$ samples, which are fully encapsulated by hexagonal boron nitride in order to protect the NbSe$_2$ from the deleterious effects of exposure to oxygen and moisture. We find that, despite the three-fold symmetry of the lattice, the magneto-transport exhibits a two-fold in-plane anisotropy for in-plane magnetic fields up to 8 Tesla. This anisotropy is restricted to the temperature region between the $T_c$ onset and $T_c$ offset, and disappears in the normal state. We propose a phenomenological model to explain this unusual observation, discussing its implications to the elucidation of Ising superconductivity.

*This work was supported by NSF DMR-1420013 through the iSuperseed program.
8:24AM F57.00003: Finite-momentum pairing in superconducting monolayer NbSe$_2$ DANIEL SHAFFER (Presenter), University of Minnesota, JIAN KANG, Physics, Florida State University, FIONA BURNELL, RAFAEL FERNANDES, University of Minnesota — The nature of the so-called Ising superconducting state in non-centrosymmetric monolayer transition metal dichalcogenides remains a subject of intense debate. Here, we study the possibility of finite-momentum pairing within a low-energy interacting microscopic electronic model for monolayer 1H-NbSe$_2$. We find that, in the presence of both Rashba and Ising spin-orbit coupling (SOC), a Fulde-Ferrell-Larkin-Ovchinnikov (FFLO)-like state is expected to emerge for sufficiently strong in-plane fields. For special orientations of the magnetic field, this FFLO state displays topological Bogolyubov Fermi surfaces or nodes depending on the center-of-mass momentum of the Cooper pairs, protected by a crystalline mirror symmetry. We also show that out of the eight symmetry-allowed interactions involving the low-energy fermions in this model, four of them favor a pair-density wave (PDW) state involving momentum transfer $K$ that may have a helical or chiral character. We investigate the stability and topology of these PDW states and their competition with the uniform superconducting phase in the presence of trigonal warping and mismatch between the $K/K'$ and the $\Gamma$ pockets.

8:36AM F57.00004: Angle dependence of $H_{c2}$ with crossover between the orbital and paramagnetic limits in 2D NbSe$_2$ HIDEKI MATSUOKA (Presenter), MASAKI NAKANO, Univ of Tokyo, TAKASHI SHITAOKOSHI, ISSP, The University of Tokyo, TAKUMI OUCHI, IMR, Tohoku Univ., YUE WANG, YUTA KASHIWABARA, SATOSHI YOSHIDA, KYOKO ISHIZAKA, MASASHI KAWASAKI, Univ of Tokyo, YOSHIMITSU KOHAMA, ISSP, The University of Tokyo, TSUTOMU NOJIMA, IMR, Tohoku Univ., YOSHIHIRO IWASA, Univ of Tokyo — Transition metal dichalcogenides (TMDs) are layered materials of abundant variety, providing emergent two-dimensional (2D) physical phenomena such as 2D superconductivity in few-layer NbSe$_2$. In the previous APS March Meeting, we reported layer-by-layer MBE growth of NbSe$_2$ thin films on insulating sapphire substrates [1], achieving relatively high $T_c$ comparable to that of bulk in the thick-enough regime. With reducing thickness, superconducting properties turned out to exhibit 2D-like behavior, realizing Ising superconductivity with large-area samples. In this presentation, we will present the experimental data on the angle dependence of $H_{c2}$ in a bilayer NbSe$_2$ film measured with a 55 T pulsed magnet at $^3$He temperature. We observed cusp-like angle dependence of $H_{c2}$ around the parallel magnetic fields even far below $T_c$ despite that $H_{c2}$ is purely dominated by the paramagnetic effect in this regime. In order to explain those results, we will propose a generalized Ginzburg-Landau model by taking into account the paramagnetic effect, which well describes the results with a microscopic physical picture. [1] H. Matsuoka et al, APS March Meeting 2018, K35.00009.
8:48AM F57.00005: Superfluid stiffness, optical spectral weight, and $T_c$ bounds in multi-band superconductors*

NISHCHHAL VERMA (Presenter), TAMAGHNA HAZRA, MOHIT RANDERIA, Ohio State Univ - Columbus — Recently we have used the optical sum rule for multi-band systems to bound the superfluid stiffness and derived upper bounds on the superconducting $T_c$ in two dimensions. These bounds were shown [PRX 9, 031049 (2019)] to be particularly important for strongly interacting, narrow band systems, and found to give useful estimates for a variety of systems ranging from cold atoms to twisted bilayer graphene. We explore here various situations where one is forced to include bands far from the chemical potential in order to have localized Wannier functions, simple interactions, or to describe flat bands. Our goal is to compute the low-energy optical spectral weight and obtain tighter bounds on the superfluid stiffness, compared to the full spectral weight that includes all interband transitions. We also gain insight into how band topology impacts optical spectral weight. We will present results for model systems with flat bands, including Lieb and Kagome lattices, and estimate $T_c$ bounds for monolayer FeSe on SrTiO$_3$ and for magic-angle twisted bilayer graphene.

*We acknowledge support from NSF-MRSEC DMR-1420451.
9:00AM F57.00006: Proximity-induced superconducting gap in the quantum spin Hall edge state of monolayer WTe$_2$* [Invited] BENJAMIN HUNT (Presenter), FELIX LÜPKE, DACEN WATERS, SERGIO C DE LA BARRERA, MICHAEL WIDOM, Carnegie Mellon Univ, JIAQIANG YAN, Oak Ridge National Laboratory, DAVID MANDRUS, University of Tennessee, Knoxville, RANDALL M FEENSTRA, Carnegie Mellon Univ — The quantum spin Hall (QSH) state was recently demonstrated in monolayers of the transition metal dichalcogenide 1T'-WTe$_2$ and is characterized by a band gap in the two-dimensional (2D) interior and helical one-dimensional (1D) edge states. Inducing superconductivity in the helical edge states would result in a 1D topological superconductor, a highly sought-after state of matter. In the present study, we use a novel dry-transfer flip technique to place atomically-thin layers of WTe$_2$ on a van der Waals superconductor, NbSe$_2$. Using scanning tunneling microscopy and spectroscopy (STM/STS), we demonstrate atomically clean surfaces and interfaces and the presence of a proximity-induced superconducting gap in the WTe$_2$ for thicknesses from a monolayer up to 7 crystalline layers. At the edge of the WTe$_2$ monolayer, we show that the superconducting gap coexists with the characteristic spectroscopic signature of the QSH edge state. Taken together, these observations provide conclusive evidence for proximity-induced superconductivity in the QSH edge state in WTe$_2$, a crucial step towards realizing 1D topological superconductivity and Majorana bound states in this van der Waals material platform.

9:36AM F57.00007: Local magnetic measurements of few-layer superconducting MoS$_2$* ALEXANDER JARJOUR (Presenter), BRIAN T SCHAEFER, GEORGE M FERGUSON, MENYOUNG LEE, KATJA NOWACK, Cornell University — Under ionic liquid gating, the transition metal dichalcogenide MoS$_2$ exhibits a superconducting dome with a maximum critical temperature of nearly 10 K in few-layer devices gated with an ionic liquid. Here, we report local magnetic measurements combined with electrical transport of this superconducting state as a function of temperature and over a limited range of carrier density. Using a scanning superconducting quantum interference device with an integrated field coil, we measure local diamagnetism at finite frequency. We report progress in extracting quantitative values of the Pearl length and superfluid density from these measurements.

9:48AM F57.00008: Superconducting properties of MBE-grown 3R-Ta_{1+x}Se_2 epitaxial thin films YUKI TANAKA (Presenter), HIDEKI MATSUOKA, MASAKI NAKANO, YUE WANG, Department of Applied Physics, The University of Tokyo, SANA SASAKURA, KAYA KOBAYASHI, Okayama University, YOSHIHIRO IWASA, Department of Applied Physics, The University of Tokyo — 2D materials research is one of the hot topics in condensed-matter science, but most studies are performed on nanometer-thick crystals fabricated by mechanical exfoliation. On the other hand, researches based on MBE-grown samples are very much limited in particular for transport studies presumably due to difficulties in making high quality thin films. We have recently established a versatile route to layer-by-layer epitaxial growth of a wide variety of 2D materials and their heterostructures on insulating sapphire substrates by MBE [1,2], opening a door for exploration of emergent transport phenomena even based on hardly-cleavable and/or thermodynamically-metastable compounds. In this presentation, we will report MBE growth of thermodynamically-metastable 3R-Ta_{1+x}Se_2 epitaxial thin films and their superconducting properties, which turned out to be very much different from those of thermodynamically-stable 2H-TaSe_2 in terms of T_c and superconducting anisotropy. [1] M. Nakano et al., Nano Lett. 17, 5595 (2017). [2] Y. Kashiwabara et al., Adv. Funct. Mater. 2019, 1900354 (2019).

10:00AM F57.00009: Type-II Ising superconductivity in two-dimensional materials with spin-orbit coupling CHONG WANG (Presenter), Carnegie Mellon University, BIAO LIAN, Princeton University, XIAOMI GUO, ZETAO ZHANG, JIAHAO MAO, BING-LIN GU, YONG XU, WENHUI DUAN, Tsinghua University — Centrosymmetric materials with spin-degenerate bands are generally considered to be trivial for spintronics and related physics. In two-dimensional (2D) materials with multiple degenerate orbitals, we find that the spin-orbit coupling can induce spin-orbital locking, generate out-of-plane Zeeman-like fields displaying opposite signs for opposing orbitals, and create novel electronic states insensitive to in-plane magnetic field, which thus enables a new type of Ising superconductivity applicable to centrosymmetric materials. Many candidate materials are identified by high-throughput first-principles calculations. Our work enriches the physics and materials of Ising superconductivity, opening new opportunities for future research of 2D materials.
10:12AM F57.00010: Insight into Two-Dimensional Borophene: Five-Center Bond and Phonon-Mediated Superconductivity*  ZHIBIN GAO (Presenter), Department of Physics, National University of Singapore, MENGYANG LI, Institute for Chemical Physics & Department of Chemistry, Graduate School of Science, Xi’an Jiaotong University, JIAN-SHENG WANG, Department of Physics, National University of Singapore — We report a previously unknown monolayer borophene allotrope and we call it super-B with a flat structure based on ab initio calculations. It has good thermal, dynamical, and mechanical stability compared with many other typical borophenes. We find that super-B has a fascinating chemical bond environment consisting of standard sp, sp² hybridizations, and delocalized five-center three-electron π bond, called π(5c-3e), relying on the natural bond orbital analysis. This exceptional distribution of electron orbitals plays a pivotal role in stabilizing the super-B chemically. Moreover, super-B has a critical temperature $T_c$ of 20.8 K at ambient condition. We attribute this high $T_c$ of super-B to the giant anharmonicity of two linear acoustic phonon branches and an unusually low optic phonon mode. These discoveries provide new insight into the chemical nature of low dimensional boron nanostructures and highlight the potential applications of designing flexible devices and high $T_c$ superconductors.

10:24AM F57.00011: Atomic-layer Rashba superconductor protected by dynamic spin-momentum locking  SHUNSUKE YOSHIZAWA, National Institute for Materials Science, TAKAHIRO KOBAYASHI, YOSHITAKA NAKATA, Chiba University, KOICHIRO YAJI, FUMIO KOMORI, SHIK SHIN, Institute for Solid State Physics, The University of Tokyo, KAZUYUKI SAKAMOTO, Osaka University, TAKASHI UCHIHASHI (Presenter), National Institute for Materials Science — The breaking of the space inversion symmetry at surfaces and interfaces leads to the Rashba-type spin-orbit coupling (SOC) in 2D materials, which can strongly affect superconductivity [1]. In this talk, I will focus on crystalline atomic-layer indium on silicon surfaces with a clear spin-splitting of the Fermi surface and in-plane spin polarizations in the momentum space [2,3]. Our electron transport measurements under ultrahigh vacuum environment reveal that its in-plane critical magnetic field exceeds the Pauli limit by a factor of 3-4 at zero temperature. Through quantitative analysis, we conclude that elastic scattering among spin-momentum-locked electronic states serves as an effective spin-orbit scattering, thereby strongly suppressing the paramagnetic pair-breaking effect [4]. The mechanism is referred to as dynamic spin-momentum locking, which is contrasted to static spin-valley locking in 2D superconductors with Zeeman-type SOC [5].

8:00AM F58.00001: Long-Range Correlations in Density Functional Theory [invited] TIM GOULD (Presenter), Queensland Micro- and Nano-technology Centre, Griffith University — Accurate and low-cost reproduction of electron correlations remains one of the most difficult problems in chemical physics. Enormous progress has been made on dealing with short-range correlations. But long-range correlations remain challenging, despite contributing to a range of important quantum chemical problems including dispersion forces [1-2], strong correlations [3-4] and charge transfer excitations [5]. This talk will discuss the origins of key types of long-range correlations in density functional theory, and consider physical, chemical and mathematical perspectives on the problem. It will discuss some low-cost solutions to difficult problems in the field, introduced by the author and others, and will highlight some of the challenges that lie ahead. It will stress the importance of the universal functional in devising new approximations, and how quantum state ensembles can help, even in "mundane" cases.

8:36AM F58.00002: Embedding tools to improve density functionals. ADAM WASSERMAN (Presenter), Chemistry, Purdue University — As is well known, standard approximations to the exchange-correlation (XC) functional often do not yield accurate energies and/or spin-densities when chemical bonds are stretched. We use density embedding theory to examine the behavior of the non-additive contribution to the XC energy and to propose physically-motivated approximations for this contribution as atoms dissociate. We also discuss a recent approach to develop improved approximations for the non-additive non-interacting kinetic energy, and why this is a challenging problem.

*This presentation is based upon work supported by the National Science Foundation under Grant No. 1900301.
8:48AM F58.00003: Kohn-Sham accuracy at a fraction of the cost: Nonlocal subsystem DFT and orbital-free DFT*  MICHELE PAVANELLO (Presenter), Rutgers University, Newark — Subsystem DFT enables first principles simulations to approach realistic time- and length-scales, and most importantly sheds light on the dynamical behavior of complex systems. The accuracy of subsystem DFT is dependent on the quality of the employed nonadditive Kinetic Energy Density Functionals (KEDF). As these are customarily of semilocal character (i.e., they depend locally on the value of the density and its gradient), so far subsystem DFT has only been able to approach weakly interacting subsystems. In this presentation, we employ latest-generation nonlocal KEDF\textsuperscript{1,2} in subsystem DFT\textsuperscript{3} and orbital-free DFT\textsuperscript{4} simulations. Our results are of KS-DFT accuracy while still keeping the computational cost at a fraction of typical KS-DFT algorithms. The developed KEDFs are accurate enough also in the context of orbital-free DFT where we show they are able to approach million-atom semiconductor systems arranged in complex structures featuring Schottky barriers and space-charge regions.

9:00AM F58.00004: Absolutely Localized Multi-reference DFT Embedding  DANIEL GRAHAM (Presenter), XUELAN WEN, Chemistry, University of Minnesota, DHABIH CHULHAI, Chemistry, University of Indianapolis, JASON GOODPASTER, Chemistry, University of Minnesota — While density functional theory (DFT) has been a workhorse for quantum mechanical chemical calculations, current implementations have several deficiencies. Systems which require a multireference description are often poorly described by current DFT methods. Quantum embedding methods provide a strategy for performing localized highly accurate calculations on chemical systems while not incurring high cost computational scaling. Dividing a system into absolutely localized subsystems -- described by only the basis functions of the subsystem atoms -- can significantly reduce computational cost. The Huzinaga projection operator based absolute localization wavefunction embedded in DFT (WF-in-DFT) embedding methods match full system WF energy differences across a diverse test set including multi-reference WF calculations embedded in DFT. We have also studied large metal organic framework (MOF) cluster models, specifically gas adsorption on an Fe-MOF-74 cluster model and can achieve within 0.22 kcal/mol of the full system CASPT2 energy at a fraction of the computational cost. The absolute localization WF-in-DFT method allows for highly accurate calculations on multireference systems beyond the scope of current techniques.
9:12AM F58.00005: Towards an orbital-free kinetic energy density functional for molecular systems*  
OMOLOLU AKIN-OJO (Presenter), ICTP-EAIFR, University of Rwanda — A new kinetic energy density functional (KEDF) for systems composed of many atoms (molecular systems) is proposed. This KEDF contains the full von-Weizsacker KEDF as well as correction terms ("Pauli KEDF") appropriate for describing fermionic systems. Two of these correction terms are investigated: one from approximations based on the kinetic energy of fermions in an infinite well potential and the other from suitable averages of the kinetic energies of atoms. The performance of these new KEDFs will be presented as well as possible routes for further development.

9:24AM F58.00006: Analytic inversion procedure for the exact non-additive kinetic potential functional $V^{nad}$  
MOJDEH BANAFSHEH (Presenter), University of California, Merced & University of Geneva, LEEOR KRONIK, Weizmann Institute of Science, TIM GOULD, Griffith University, DAVID STRUBBE, University of California, Merced, TOMASZ A. WESOLOWSKI, University of Geneva — The non-additive kinetic potential functional $V^{nad}$ is a key issue in density-dependent embedding methods, such as Frozen Density Embedding Theory and Partition-DFT. $V^{nad}$ is a bifunctional of pairs of specific electron densities $\rho_A$ and $\rho_B$. We report here an inversion procedure to generate reference $V^{nad}$ for weakly overlapping $\rho_A$ and $\rho_B$. To obtain the exact $V^{nad}$ we used an analytical inversion procedure that we proposed (M. Banafsheh, T.A. Wesolowski, Int. J. Quant. Chem. 118 (2018): e25410). We discuss the constraints on the choice of electron densities to assure their admissibility. Mathematical challenges of satisfying these constraints will be presented in detail. The potential at small overlap is constructed for various diatomic systems of four electrons at different interatomic distances. These results are compared with the potential obtained using common kinetic functional approximations. $V^{nad}$ is also presented for some diatomic systems including more than 4 electrons in which two electrons are localized with high precision in space and the accuracy of $V^{nad}$ is assured. We are now studying the forward Kohn-Sham problem for some small diatomic systems using the analytically inverted potential and comparing with the standard Kohn-Sham approach.
9:36AM F58.00007: Bond energies of molecules using optimal transport theory for the strictly-correlated-electron (SCE) limit of Density-Functional-Theory*  
KSHITEEJ DESHMUKH (Presenter), KAUSHIK DAYAL, Carnegie Mellon University — **Standard Kohn-Sham DFT starts from a mean-field approximation: the kinetic energy is modeled exactly, while the electron-electron interactions are modeled through a split into a mean-field term, and corrections from the exchange-correlation term. The SCE limit starts from the opposite limit: the electron-electron interactions are assumed to dominate over the kinetic energy, and hence it is a semi-classical limit. It is hence well suited to study strongly-correlated situations, e.g. bond breaking. While the SCE limit includes many-body interactions, it can be identified as a problem from Optimal Transport theory with Coulomb cost function. Hence it can be solved by a nested optimization in its dual (Kantorovich) formulation. We incorporate the Kantorovich solution within the KS-DFT framework and solve it using the finite element method. Bond-energy curve is obtained using this method for hydrogen molecule, and is compared against other exchange-correlation models to show the improved results. We then investigate bond-breaking in ethane and other small molecules using the SCE limit.**

9:48AM F58.00008: How accurate can a metaGGA+vdW functional be simultaneously for chemisorption and physisorption of molecular adsorption on transition metal surfaces?*  
MANISH KOTHAKONDA (Presenter), RUIQI ZHANG, JINLIANG NING, JAMES FURNESS, JIANWEI SUN, Tulane Univ — Understanding molecular adsorption on transition metal surfaces underpins many problems in heterogeneous catalysis. Accurately predicting the adsorption energies has been a challenging task as simultaneously capturing chemical and van der Waals (vdW) bonds in a single functional is difficult. In this work, we combine the semi-local meta-GGA made simple (MGGA_MS) functional with the rvv10 vdW correction [1-3]. We re-parametrize the functional by fitting to the atomization energies of covalently bonded molecules and the Ar2 binding curve. The resulting MGGA_MS + rVV10 is validated against a set of 38 systems including chemisorption and physisorption features with experimental [4] adsorption data.

10:00AM F58.00009: Asymptotic behavior of the exchange-correlation energy density and the Kohn-Sham potential in density functional theory: exact results and strategy for approximations

ELI KRAISLER (Presenter), Hebrew Univ of Jerusalem — Density functional theory (DFT) is nowadays the leading theoretical framework for quantum description of materials from first principles. The predictive power of DFT critically depends on an accurate approximation to the generally unknown exchange-correlation (xc) energy functional. Approximations to the xc functional can be constructed from first principles by satisfying known properties of the exact functional. In this talk I focus on two such exact properties: the asymptotic behavior of the xc energy density per particle, $e_{xc}[n](r)$, and the asymptotic behavior of the Kohn-Sham potential, $v_{xc}[n](r)$, in finite many-electron systems. It is shown that these two properties are independent: fulfillment of one does not guarantee the other. In this process, a new quantity, the xc hole response function, is defined, some of its properties are deduced and its exact exchange part is analytically derived. A strategy for development of advanced approximations for exchange and correlation with a correct asymptotic behavior is suggested [1].

10:12AM F58.00010: Methods of corrections to to GEA approximations of the Pauli potential

JEREMY REDD (Presenter), Physics, Utah Valley University, ANTONIO CANCIO, Physics and Astronomy, Ball State University — In recent years many advances have been made in Orbital-Free Density Functional Theory (OFDFT), which attempts to remove orbitals from the Kohn-Sham DFT approach, either completely, or by approximating the kinetic energy density from meta-GGA exchange correlation functionals. The difficulty in OFKE models is in modeling the Pauli energy, the contribution to the KE of Pauli statistics. One aspect of this problem is correctly producing the OF Pauli potential, the functional derivative of the Pauli KE. Recent mathematical analysis of orbital free kinetic energy models based on Gradient Expansion Approximations (GEA)s, like the Airy gas model, have offered insight in modeling the Pauli potential for neutral atoms. However all of these models suffer from gross inaccuracies in the nuclear cusp region, as well as an unexpected deviation in the core. The exact Pauli potential approaches a constant near the nucleus related eigenvalue of the lowest occupied atomic orbital, but all GEAs become infinitely negative at the singularity. We propose a smooth non-analytic stitching function to correct the error in the near nuclear region for Pauli potential GEAs, and explore the outer core. This is similar to work done by Perdew and Constantin as well as previous work from this group done on KEDs.
10:24 AM F58.00011: Practical Density Functional Theory Beyond the Zero-Sum Limit: M11plus
PRAGYA VERMA, University of Minnesota, BENJAMIN JANESKO (Presenter), Texas Christian Univ, YING WANG, XIAO HE, East China Normal University, GIOVANNI SCALMANI, MICHAEL J. FRISCH, Gaussian, Inc., DONALD G TRUHLAR, University of Minnesota — Conventional approximate DFT functionals are based on what exchange would be a nearly homogeneous electron gas. This model effectively uses like-spin exchange to model opposite-spin correlation, producing a "zero-sum" tradeoff in performance for some classes of problems, including bond energies vs. barrier heights or valence vs. Rydberg excitations. We argue that including new ingredients in a functional can provide beyond-zero-sum broad accuracy. We demonstrate this by adding a new ingredient to the flexible M11 long-range-corrected hybrid meta functional form. The new ingredient is an inexpensive rung-3.5 bound to the exact exchange energy density. The M11 form was reoptimized with these terms, producing a functional called M11plus. Tests for thermochemistry, kinetics, and response properties suggest M11plus is one of the most broadly accurate occupied-orbital-only DFT functionals available to date.

10:36 AM F58.00012: Numerical analysis of thermodynamic limit extrapolation power-laws in the uniform electron gas using connectivity-twist-averaged coupled cluster doubles theory
TINA MIHM (Presenter), BINGDI YANG, LAURA WEILER, University of Iowa, ALEXANDRA MCISAAC, Chemistry, MIT, ANDREAS GRUENEIS, Vienna University of Technology, SAI RAMADUGU, JAMES SHEPHERD, University of Iowa — We recently developed a coupled-cluster theory method in the uniform electron gas (UEG) for improving twist averaging in solids [1]. The method finds a special twist angle that gives comparable results to conventional twist averaging at a reduced cost. Here, we apply this new method to calculate the thermodynamic limit energies of the uniform electron gas across a range of densities. The high-density limit is then used to derive general power laws for extrapolation. Time permitting, we will also show preliminary results for real systems using the Vienna ab-initio software package [2][3].

*We thank University of Iowa for their funding.

Tuesday, March 3, 2020 8:00 AM - 11:00 AM
Using magnetic band theory and topological indices obtained from Topological Magnetic Quantum Chemistry (TMQC), we have performed the first high-throughput of about 500 magnetic topological materials and have discovered over 100 magnetic enforced semimetals and topological insulators. This knowledge is crucial for correct ab-initio calculations of the materials' band structure, which we have performed for each of those compounds including complete phase diagrams at different values of Hubbard potential in LDA+U. Using an in-house code for finding the magnetic band representations at high symmetry points, we then feed this data into the topological machinery of TMQC to determined the topological materials, as well as the obstructed atomic limits. We then pick several candidates for showcasing new topological physics and analyze the topological trends in the materials upon varying interactions.
Computational study and discovery of antiferromagnetic topological insulators [Invited] MIKHAIL OTROKOV (Presenter), Materials Physics Center (MPC) — Magnetic topological insulators (MTIs) are narrow gap semiconductor materials that combine non-trivial band topology and magnetic order. Unlike their nonmagnetic counterparts, MTIs may have some of the surfaces gapped due to breaking the time-reversal symmetry, which enables exotic phenomena having potential applications in spintronics. So far, MTIs were only created by means of doping nonmagnetic TIs with 3\textit{d} transition metal atoms however, such an approach leads to strongly inhomogeneous magnetic and electronic properties of these materials, restricting the observation of important effects to very low temperatures. Finding intrinsic MTI, i.e. a stoichiometric well-ordered compound, could be an ideal solution to these problems. Using \textit{ab initio} calculations, we predicted the van der Waals layered compound MnBi\textsubscript{2}Te\textsubscript{4} (MBT) to be the first antiferromagnetic TI (AFMTI) \cite{1,2}. The interlayer AFM ordering makes MBT invariant with respect to the combination of the time-reversal (Θ) and primitive-lattice translation ($T_{1/2}$) symmetries, $S=ΘT_{1/2}$, which gives rise to the $Z_2$ classification of AFM insulators. We find $Z_2=1$ for MnBi\textsubscript{2}Te\textsubscript{4}, which confirms its topologically nontrivial nature. To date, many experimental groups confirmed the AFMTI state in MBT, with the first observation reported in Ref. \cite{1}.

In the 2D limit, MBT is expected to show a unique set of thickness-dependent magnetic and topological transitions, which drive it through FM and (un)compensated AFM phases, as well as quantum anomalous Hall (QAH) and zero plateau QAH states \cite{2}. The latter was predicted to host the axion insulator phase.

The discovery of the first AFMTI opens a new field that focuses on intrinsically magnetic stoichiometric compounds: several MBT-derived MTI-candidates were experimentally synthesized right away, that will be discussed in the talk along with other AFMTI candidates predicted \textit{ab initio}.

Computational Search for Magnetic and Non-magnetic 2D Topological Materials using Spin-orbit Spillage KAMAL CHOUDHARY (Presenter), KEVIN GARRITY, FRANCESCA TAVAZZA, Materials Measurement Lab, National Institute of Standards and Technology — Intrinsic two-dimensional materials have a variety of properties that make them attractive for potential topological devices. Using density functional theory-based spin-orbit spillage, Wannier-interpolation, and related techniques, we identify topologically non-trivial intrinsic 2D insulators and semimetals, including both magnetic and non-magnetic materials. Using JARVIS-DFT 2D material dataset we first identify materials with high spin-orbit spillage among 683 materials, resulting in 108 materials with high-spillage values. Then, we use Wannier-interpolation to carry-out Z2, Chern-number, anomalous Hall conductivity, Curie temperature, and edge state calculations. We identify topological insulators and semimetals such as quantum spin-hall insulators (QSHI), quantum anomalous-hall insulators (QAHI), and semimetals. For a subset of predicted QAHI materials, we run GW+SOC and GGA+U calculations. We find that as we introduce many-body effects, only few materials retain non-trivial band-topology, suggesting the importance of high-level DFT methods in predicating 2D topological materials. However, as an initial step, the automated spillage screening and Wannier-approach provides useful predictions for finding new topological materials.
9:00AM F59.00004: Automated Critical Temperature Prediction and High-Throughput Search for Composite Quantum Materials  
NATHAN C. FREY (Presenter), University of Pennsylvania, MATTHEW HORTON, JASON MUNRO, Lawrence Berkeley National Laboratory, VIVEK SHENOY, University of Pennsylvania, KRISTIN PERSSON, Lawrence Berkeley National Laboratory — Composite materials with coexisting quantum phases offer exciting opportunities for solid-state device applications and exploring new physics emerging from the interplay between effects including topology, magnetism, and ferroelectricity. However, both the computational design and experimental realization of magnetic topological materials and multiferroics are confounded by the difficulties inherent to predicting and controlling magnetic behavior, which arises from strong electron correlations. We present a workflow to automate the calculation of exchange parameters and critical temperatures with density functional theory and Monte Carlo simulations. We use our recently developed Python Topological Materials package to screen materials for non-trivial band topology. We then apply this approach to suspected magnetic materials in the Materials Project database. By identifying layered materials, we also accelerate the discovery of van der Waals materials with composite topological quantum phases and multiferroic properties. Our method can be used to screen for thermodynamically stable, robust composite quantum materials for solid-state devices and exploring exotic physics like the quantum anomalous Hall effect and axion electrodynamics.

9:12AM F59.00005: Computational search for magnetic topological materials in Eu compounds*  
LIN-LIN WANG (Presenter), Ames Lab, ROBERT-JAN SLAGER, Department of Physics, Harvard University, HOI CHUN PO, Department of Physics, MIT, ADAM KAMINSKI, Department of Physics and Astronomy, Iowa State University, ASHVIN VISHWANATH, Department of Physics, Harvard University, PAUL C CANFIELD, Department of Physics and Astronomy, Iowa State University — Topological materials are of great interests for both basic research and future technology. Recent developments of symmetry indicators and similar approaches to diagnose band structure topology have resulted in databases of non-magnetic topological materials via high throughput band structure calculations. However, magnetic topological materials have been much less explored. One of the reasons is that the magnetic ground state structures are not readily available like crystallography databases and also different magnetic configurations can be competing in energy. But this also offers the opportunity to use magnetism to control topological properties of materials. Here we have explored Eu compounds using band structure calculations based on density functional theory and found several Eu compounds can host ferromagnetic Weyl, anti-ferromagnetic Dirac as well as anti-ferromagnetic topological insulating states depending on different magnetic configurations.

*This work is supported by the Center for Advancement of Topological Semimetals, an Energy Frontier Research Center funded by the US DOE Basic Energy Sciences, through the Ames Laboratory under Contract No. DE-AC02-07CH11358.
In [Bradlyn et al., *Nature* (2017)], we introduced Topological Quantum Chemistry (TQC) - a real-space predictive theory of band topology and degeneracy constructed from graph theory and atomic orbitals in the 230 time-reversal- ($T$-) symmetric space groups (SGs). TQC subsequently fueled the identification of tens of thousands of topological materials, and the discovery of novel topological insulating (TI) phases, including "higher-order" TIs. However, the 230 SGs only represent a fraction of the 1651 Shubnikov SGs, which characterize the symmetries of both magnetic and non-magnetic crystals. In this talk, we extend TQC to the magnetic Shubnikov SGs (MSGs), forming the complete theory of Magnetic Topological Quantum Chemistry (MTQC). Using MTQC, we construct a complete classification of the magnetic atomic limits [i.e., magnetic Elementary Band Representations (MEBRs)]. Through the MEBRs, we also obtain the little-group corepresentations of the MSGs, complete eigenvalue indicators for strong and fragile magnetic TIs and semimetals, and all possible mean-field band connectivities in crystals with lattice-commensurate magnetism. We introduce new tools on the Bilbao Crystallographic Server for accessing this information, and discuss magnetic topological materials identified using MTQC.

We perform a comprehensive study of band degeneracies protected by 3D magnetic space groups in the bands of magnons and of electrons, and obtain all new classes of degeneracies (nodes) that cannot appear in non-magnetic materials. The new nodes protected by magnetic space groups are unified and classified using the group cohomology of the corresponding point group. We propose a method to find if the effective theory of any new degeneracy has linear dispersion in all three directions, and use the method to identify all linear-dispersing nodes of four or higher degeneracy.
9:48AM F59.00008: Searching for Double Dirac Fermions*  
TANYA BERRY (Presenter), Johns Hopkins University, RAFAL WAWRZYNCKAZ, JOHANNES GOOTH, CLAUDIA FELSER, Chemical Physics of Solids, Max Planck Institute, TYREL MCQUEEN, Johns Hopkins University — The field of topological materials is developing rapidly, exhibiting new physical phenomena and inviting potential applications in the emerging fields of quantum computing and sensing. Normally, the maximal degeneracy of states in any electronic system is six. Topological considerations predict that in certain materials the double group cross product of two irreducible representations (irreps.) or the cross product of one irrep. on itself can yield eight states that are degenerate in energy at a high symmetry point in reciprocal space. Materials including CuBi$_2$O$_4$ and PdBi$_2$O$_4$ have been previously predicted to be such 8-fold fermion or double Dirac systems on the basis of their symmetries. However, their insulating behavior hinders photoemission and transport characterizations, which are crucial for unambiguous identification. Here we present a strategy for designing real materials with 8-fold fermions based on chemical principles and provide an update on experimental detection of this novel topological state.

10:00AM F59.00009: Axion coupling in the hybrid Wannier representation*  
NICODEMOS VARNAVA (Presenter), Physics and Astronomy, Rutgers University, IVO SOUZA, Centro de Fisica de Materiales, Universidad del Pais Vasco (UPV/EHU), DAVID VANDERBILT, Physics and Astronomy, Rutgers University — One of the most important quantized responses of 3D topological insulators (TIs) is due to the axion coupling \( \theta \). Strong TIs, axion insulators, and the topological magnetoelectric effect owe their robustness to the quantization of the axion coupling (the axion \( \mathbb{Z}_2 \) index). Time reversal was the first quantizing symmetry to be recognized, but recently a plethora of magnetic symmetries were found to have the same effect. After we enumerate all the quantizing symmetries, we explore how the nature of these symmetries affects the topological properties of the system. One tool that has proven especially useful in that respect is the hybrid Wannier (HW) representation. In this representation the quantizing symmetries can be divided into three distinct classes. By analyzing each of them in turn, we are able to explain whether the connectedness of the HW band structure in a topological phase is robust or fragile. Furthermore, we clarify the correspondence between the connectedness of the HW band structure and the appearance of either topologically protected metallic surfaces or insulating surfaces with half-quantized anomalous Hall response. We corroborate our results with various tight-binding models.

**10:12AM F59.00010: Domain-wall states in Chern insulator with in-plane ferromagnetism**

YAFEI REN (Presenter), TAO HOU, ZHENHUA QIAO, Department of Physics, University of Science and Technology of China (USTC) — Topological phase is global and beyond the Landau paradigm of phases described by local order parameters. In this work, we report the electronic and transport properties of in-gap domain-wall states between domains with the same topology but different local magnetic orders, which lie in plane. We consider a buckled honeycomb lattice model that can host Chern insulating phase from in-plane magnetization with azimuthal angle \( \varphi_0 \), which breaks the three-fold rotation symmetry of original lattice. The topological phase remains the same at different \( \varphi_p = \varphi_0 + 2\pi p/3 \) (\( p=0-2 \)). Along the domain wall, we find one-dimensional in-gap states whose electronic dispersion depends on the magnetic structure and domain wall width despite the same Chern number at different domains. At a symmetric \( Y \)-shape junction formed by three regions of different \( \varphi_p \), we find counter-intuitive chiral current partition law that is tunable by electrical means. In a network by combining \( Y \)-shape junction to form a honeycomb, we find that the in-gap states form nearly flat Bloch bands with different topological Chern numbers providing a intriguing platform to investigate many-body effects.

**10:24AM F59.00011: Half-integer quantization of Hall conductance in semi-magnetic topological insulator**

MASATAKA MOGI (Presenter), YOSHIHIRO OKAMURA, Univ of Tokyo, MINORU KAWAMURA, RYUTARO YOSHIMI, RIKEN CEMS, KENJI YASUDA, Univ of Tokyo, ATSUSHI TSUKAZAKI, Tohoku University, KEI TAKAHASHI, RIKEN CEMS, TAKAHIRO MORIMOTO, Univ of Tokyo, NAOTO NAGAOSA, RIKEN CEMS, MASASHI KAWASAKI, YOUTAROU TAKAHASHI, Univ of Tokyo, YOSHINORI TOKURA, RIKEN CEMS — The emergence of two-dimensional (2D) Dirac fermions in condensed matter systems, such as graphene and three-dimensional (3D) topological insulators, has greatly deepened quantum Hall physics. The anomalous integer quantization of Hall conductance as observed in graphene is understood by the half-integer topological number of each Dirac cone. However, the Dirac cones always appear in pairs in such 2D lattices, hiding the half-integer number from experimental observations. The 3D topological insulators, on the other hand, can possess a single Dirac cone in each top and bottom surface, serving as an ideal system to explore the half-integer quantization phenomena. Here, we will report the observation of half quantized Hall conductance in ‘semi-magnetic’ topological insulator films, where one of the surfaces is gapped by magnetic doping whereas the opposite one remains non-magnetic and gapless. Using time-domain terahertz magneto-optical spectroscopy as well as electrical transport, we observed half quantized Faraday and Kerr rotations and half quantized Hall conductivity at zero fields. This result provides experimental evidence for the predicted fractional quantized state in 3D topological insulators.

10:36AM F59.00012: Antiferromagnetism and spin density waves in Dirac semimetals
GRIGORY BEDNIK (Presenter), University of California, Santa Cruz — We perform mean-field study of possible magnetic instabilities in Dirac semimetals. We find that Dirac electrons naturally host antiferromagnetic or spin density wave ground states, though their specific configurations may vary depending on specific model, as well as chemical potential and temperature. We also discuss paramagnetic susceptibility in Dirac semimetals. In the cases, when Dirac electrons do not have orbital momentum, the magnetic properties may be $\mu$ and $T$ independent.

*NSERC of Canada

10:48AM F59.00013: Intrinsic magnetic topological insulator $\text{MnBi}_2\text{Te}_4$
JIAHENG LI (Presenter), DUAN WENHUI, YONG XU, Department of Physics, Tsinghua University — The interplay of magnetism and topology offers great opportunities to explore variant emerging topological quantum phenomena. Here we will present that van der Waals layered $\text{MnBi}_2\text{Te}_4$-related materials intrinsically host nontrivial band topology, which possess A-type antiferromagnetism characterized by ferromagnetic intralayer and antiferromagnetic interlayer coupling. Extremely rich 2D and 3D topological quantum states emerge in $\text{MnBi}_2\text{Te}_4$, including 3D antiferromagnetic topological insulator with the long-sought topological axion states on the surface, the simple magnetic Weyl semimetal with one pair of Weyl points, as well as intrinsic axion insulators and QAH insulators in even- and odd-layer films, respectively [1]. Furthermore, we will show a series of magnetically controllable topological quantum phase transitions in the material [2]. Relevant experimental progresses will also be introduced [3-5].

Tuesday, March 3, 2020 8:00 AM - 10:48 AM

Session F60 DMP: Topological Materials: Magnetism and Hybrid Structures
Mile High Ballroom 4A - Jisoo Moon, US Naval Research Laboratory - Tag(s): Focus
WENBO WANG (Presenter), University of California, Santa Barbara — Quantum anomalous Hall effect (QAHE), which is related to the momentum-space Berry phase, was experimentally realized in Cr-doped (Bi,Sb)$_2$Te$_3$ (BST) and V-doped BST thin films. The full quantization of anomalous Hall effect (AHE) in these two systems requires extremely low temperature (<50mK) [1][2]. Magnetic inhomogeneity has been proposed as one of the main reasons that limit the temperature for the realization of QAHE. In the first part, we will present direct visualization of long-range ferromagnetism in the Cr,V co-doped BST films, by using the MFM and in-situ transport measurement[3]. The magnetization reversal process reveals typical ferromagnetic domain behavior, i.e. domain nucleation and domain wall propagation. In the second part, we will discuss topological Hall effect (THE), a real-space Berry phase effect that originates from the non-coplanar spin textures[4]. Intrinsic THE was revealed at different temperatures in the magnetic topological insulator heterostructure Sb$_2$Te$_3$/V-doped Sb$_2$Te$_3$, after a back-gate voltage was applied to zero the AHE. The high-temperature THE persists above the Curie temperature, which originates from the spin chirality fluctuations[5]. At temperatures well below the Curie temperature, THE emerges around the coercive fields, when the ferromagnetic bubble domains form. The low-temperature THE likely results from the static topological charges at the chiral domain walls.

8:36AM F60.00002: Magneto-transport in Pb\textsubscript{x}Sn\textsubscript{1-x}Se Quantum Well*  

JIASHU WANG (Presenter), XINYU LIU, LOGAN S RINEY, JACEK K. FURDYNA, BADIH A ASSAF, University of Notre Dame — Pb\textsubscript{x}Sn\textsubscript{1-x}Se (0.16<x<0.4) is a narrow gap semiconductor that exhibits a topological phase transition to a topological crystalline insulator (TCI) when the concentration of Sn increases. It is a valley degenerate topological system that can exhibit exotic quantum Hall effects and strong coupling between the crystal and electronic structures. Here we investigated the transport properties of PbEuSe/Pb\textsubscript{x}Sn\textsubscript{1-x}Se/PbEuSe quantum wells, of which the thickness is 30 and 50nm and x=0.3. By doping Bismuth during the growth, we can efficiently tune the carrier type from p type to n type with carrier densities as low as 1E18cm\textsuperscript{-3} and high mobility (>10000cm\textsuperscript{2}/ (Vs)). We found out that the sample showed linear magnetoresistance starting at relatively low field (<1T). The slope of ΔR/R\textsubscript{0} is proportional to the mobility. We applied several model to explain this phenomenon. Further process like gating is also used to investigate the mechanism. With high mobility and low carrier density in the quantum well, it will be a great platform to study 2D quantum phenomenon in the landau quantized regime.

*Jiashu Wang and Badih A. Assaf acknowledge ND-Nano for funding support.

8:48AM F60.00003: Magnetotransport properties in antimony single crystals*  

PAUL C. W. CHU (Presenter), ZHENG WU, LIANGZI DENG, MELISSA GOOCH, TREVOR BONTKE, Texas Center for Superconductivity and Physics Department at the Univ of Houston — The magnetoresistance of antimony single crystals has been measured with the measuring current perpendicular and parallel to the magnetic field, respectively. Extremely large positive transverse magnetoresistance (TMR) up to 1,000,000% was obtained in a magnetic field of 7 T. Field dependence of TMR followed the power law MR ∝ H\textsuperscript{2α} in all measured temperatures from 2 K to 300 K. The extremely large TMR is attributed to the well compensated electron and hole carriers with high mobility. A very pronounced negative longitudinal magnetoresistance (LMR) at high field and a valley at zero field was observed. The general behavior appears to be consistent with the chiral magneto effect predicted in quantum solids. Moreover, a very unusual negative potential from voltage leads was detected by IV curve, dc, and ac resistance measurements at high magnetic field. This observation cannot be understood in terms of available theories and may be related to some exotic topological characteristics predicted for antimony.

*The work performed at TcSUH is supported by US Air Force Office of Scientific Research Grant FA9550-15-1-0236, the T. L. L. Temple Foundation, the John J. and Rebecca Moores Endowment, and the State of Texas through the Texas Center for Superconductivity at UH.
**9:00AM F60.00004: Thickness Dependence of Electronic Properties of Topological Antiferromagnet MnBi$_2$Te$_4$ Films**  
YIFAN ZHAO (Presenter), GUANG WANG, LINGJIE ZHOU, Pennsylvania State University, DMITRY OVCHINNIKOV, University of Washington, FEI WANG, LING ZHANG, HEMIAN YI, BAITAO ZHANG, MOSES HUNG-WAI CHAN, Pennsylvania State University, XIAODONG XU, University of Washington, CUI-ZU CHANG, Pennsylvania State University — The prerequisite for the realization of the quantum anomalous Hall (QAH) state is an interplay between topology and magnetism. More recently, MnBi$_2$Te$_4$ was experimentally demonstrated to be a material in which the topological and magnetic states intrinsically coexist. The QAH and axion insulator states were predicted in thin films of MnBi$_2$Te$_4$ when the number of layers is odd and even, respectively. Here, we synthesized MnBi$_2$Te$_4$ thin films with thicknesses down to one layer using molecular beam epitaxy (MBE) and systematically studied the thickness dependence of electronic properties. Both Hall and Magneto-Optical Kerr Effect measurements show a clear ferromagnetic hysteresis in the one-layer sample. For films thicker than one layer, similar to the exfoliated MnBi$_2$Te$_4$ devices, the samples show a small ferromagnetic hysteresis loop at the low magnetic field and spin flop transitions at the high magnetic field. We also found the Hall resistance under zero magnetic field displays an odd/even oscillation, i.e., the samples with odd (even) layers exhibit an anomalous Hall (AH) hysteresis loop with a negative (positive) sign.

**9:12AM F60.00005: Discovery of a quantum topological kagome magnet by vector magnetic field-based STM**  
JIAXIN YIN (Presenter), Physics, Princeton University, WENLONG MA, School of Physics, Peking University, SONGTIAN SONIA ZHANG, TYLER COCHRAN, Physics, Princeton University, XITONG XU, School of Physics, Peking University, NANA SHUMIYA, BIAO LIAN, ZHIDA SONG, Physics, Princeton University, KUN JIANG, Physics, Boston College, TAY-RONG CHANG, Physics, National Cheng Kung University, TITUS NEUPERT, Physics, University of Zurich, ZIQIANG WANG, Physics, Boston College, NAN YAO, Physics, Princeton University, SHUANG JIA, School of Physics, Peking University, ZAHID HASAN, Physics, Princeton University — Kagome magnets have been known to exhibit rich topologically based vector magnetic field responses, including giant and anisotropic spin-orbit tunability (J.-X. Yin et al. Nature 562, 91-95 (2018)) and negative flatband magnetism (J.-X. Yin et al. Nature Physics 15, 443-448 (2019)). Here we use the same vector magnetic field-based STM technique combined with Berry curvature sensitive transport to discover a new quantum topological kagome magnet. We observe striking Landau quantization of the kagome lattice, dissipationless chiral edge state, and quantum-limit Hall response. These combined results point to the realization of a high-temperature quantum topological kagome magnet.

9:24AM F60.00006: Quantum oscillations in thin films of antiferromagnetic kagome metal FeSn

MINYONG HAN (Presenter), HISASHI INOUE, Massachusetts Institute of Technology MIT, MUN K. CHAN, National High Magnetic Field Laboratory, LANL, DAVID E GRAF, National High Magnetic Field Laboratory, Florida State University, LINDA YE, TAKEHITO SUZUKI, JOSEPH G CHECKELSKY, Massachusetts Institute of Technology MIT — FeSn is an antiferromagnetic metal, consisting of two-dimensional layers of corner-sharing triangles of Fe, separated by honeycomb Sn spacer layers. This geometrical arrangement of Fe atoms, known as the kagome lattice, is predicted to give rise to Dirac fermions and topological flat bands. Recent photoemission and quantum oscillation studies on FeSn bulk single crystals have experimentally confirmed the existence of these features in their electronic structures [1]. Here we report the quantum oscillation studies on thin films of FeSn. The observed oscillation frequency reproduces the previous measurements on FeSn bulk single crystals. Temperature and field-angle dependent oscillation frequencies respectively reveal the scattering timescale and morphology of the observed Fermi pocket. The realization of high quality FeSn thin films offers a promising platform to explore the interplay of magnetism and electronic topology via quantum confinement or electrostatic gating [2].

9:36AM F60.00007: Dirac-Surface-State-Modulated Bilinear Magnetoresistance in Topological Insulators*

FEI WANG (Presenter), LING ZHANG, ZIQIAO WANG, YIFAN ZHAO, RUN XIAO, GUANG WANG, HEMIAN YI, LINGJIE ZHOU, RUOXI ZHANG, BAITAO ZHANG, MOSES HUNG-WAI CHAN, NITIN SAMARTH, QI LI, Department of Physics, Pennsylvania State University, WEIWEI ZHAO, School of Materials Science and Engineering, Harbin Institute of Technology, CUI-ZU CHANG, Department of Physics, Pennsylvania State University — Topological insulators (TIs) are a class of quantum materials in which the interior is insulating but electrons can travel through the two-dimensional (2D) conducting surfaces known as Dirac surface states. The Dirac surface states harbor a helical spin texture and thus provide a good platform for potential spintronic applications. Prior experiments have shown that the helical spin texture of the Dirac surface states can be resolved using bilinear magnetoresistance (BMR) measurements. The observation of BMR in previous studies was attributed to the presence of the hexagonally warped Fermi surface at the Dirac surface state in samples with heavy doping. Here, we fabricated a series of (Bi$_{1-x}$Sb$_x$)$_2$Te$_3$ samples with different $x$ and systematically studied their BMR. When the chemical potential is near the Dirac point and the warping effect of the Dirac surface state disappears, the BMR reaches a maximum rather than vanishes. This observation is further confirmed in a dual-gate-tuned device. Our work indicates that BMR has more complex origins than the warping effect of the Dirac surface state alone.

Dirac Band Engineering of Topological Insulator/Graphene Hybrid Structures*  
GUANG WANG (Presenter), Department of Physics, National University of Defense Technology, YIFAN ZHAO, Department of Physics, The Pennsylvania State University, HUIXIA FU, Department of Condensed Matter Physics, Weizmann Institute of Science, ZENGLE HUANG, Department of Physics and Astronomy, Rutgers University, FEI WANG, HEMIAN YI, TIMOTHY PILLSBURY, LINGJIE ZHOU, Department of Physics, The Pennsylvania State University, CHENGYE DONG, JOSHUA ROBINSON, Department of Materials Science and Engineering, The Pennsylvania State University, NITIN SAMARTH, Department of Physics, The Pennsylvania State University, WEIDA WU, Department of Physics and Astronomy, Rutgers University, BINGHAI YAN, Department of Condensed Matter Physics, Weizmann Institute of Science, CUI-ZU CHANG, Department of Physics, The Pennsylvania State University — Dirac materials such as graphene and topological insulators (TI) have attracted much attention because of their unique electrical properties. Stacking these two Dirac materials to form a heterostructure provides a platform for the exploration of the interesting physics of coupled Dirac fermions. We recently used molecular beam epitaxy to fabricate the (Bi$_{1-x}$Sb$_x$)$_2$Te$_3$/graphene hybrid structures and systematically studied the electronic band structures as a function of $x$ and thickness. Because the ratio between the lattice constants of Sb$_2$Te$_3$ and graphene is $\sqrt{3}$, the Dirac cone of graphene can be folded to the $\Gamma$ point of the Brillouin zone of Sb$_2$Te$_3$. The coexistence of two different Dirac low-energy states is indeed observed in angle-resolved photoemission spectroscopy measurements. This phenomenon is further demonstrated by scanning tunneling microscopy results and first-principles calculations. Our work is of great importance for understanding the interplay of Dirac fermions across the TI/graphene interface and paves a new way to study band engineering in Dirac materials.

Topological Properties of SnSe/EuS and SnTe/CaTe Heterostructures  
SHUYANG YANG (Presenter), CHUNZHI WU, NOA MAROM, Carnegie Mellon University — We use density functional theory (DFT) to study epitaxial interfaces of the topological crystalline insulators SnSe and SnTe with the ferromagnetic semiconductor EuS and the nonmagnetic semiconductor CaTe, respectively. We consider both surface slab models and periodic "sandwich" heterostructures. We find that a gapped surface state arises in the SnSe/EuS interface due to the magnetic proximity effect. By comparison, the gapless topological surface state at the interface of SnTe/CaTe is unperturbed.
Synthesis of hybrid oxide/chalcogenide interfaces to explore topological crystalline insulator properties

STEPHEN D ALBRIGHT (Presenter), Department of Physics, Center for Research on Interface Structures and Phenomena, Yale University, KE ZOU, Department of Physics & Astronomy, Stewart Blusson Quantum Matter Institute, The University of British Columbia, SHUHANG PAN, Department of Physics, Center for Research on Interface Structures and Phenomena, Yale University, FREDERICK J WALKER, CHARLES H AHN, Department of Applied Physics, Center for Research on Interface Structures and Phenomena, Yale University — The class of topological crystalline insulators (TCIs), including SnTe, provides new opportunities to explore topological behaviors. Surface carriers in TCIs experience the same spin-momentum locking as conventional topological insulators, but are protected by crystalline symmetry, which makes possible controlling topological states in SnTe through electric field gating. This work presents growth of SnTe thin enough to achieve topological state control on a substrate, SrTiO$_3$, easily integrated into field-effect devices. We grow SnTe films by co-sublimation-deposition, where a high-quality thick film is controllably thinned by elevating the substrate temperature in constant flux. X-ray diffraction and atomic force microscopy confirm SnTe films grown by this process are uniform down to 7 nm. Carrier density over a range of film thickness, extracted from Hall measurements, reveals surface-dominated transport in SnTe films less than 16 nm. Weak antilocalization (WAL) behavior observed in magnetotransport is consistent with topological conduction through these surface states, and we fit WAL to theory to extract details of the topological transport. The growth method presented here opens up future opportunities to design heterostructures to further explore topological behavior.
10:24AM F60.00011: Modular Arithmetic with Nodal Lines: Drumhead Surface States in ZrSiTe*  LUKAS MUECHLER (Presenter), Center for Computational Quantum Physics, Flatiron Institute, ANDREAS TOPP, Max Planck Institute for Solid State Research, RAQUEL QUEIROZ, Department of Condensed Matter Physics, Weizmann Institute of Science, MAXIM KRIVENKOV, ANDREI VARYKHALOV, Helmholtz-Zentrum Berlin fuer Materialien und Energie, JENNIFER CANO, Department of Physics and Astronomy, Stony Brook University, CHRISTIAN R AST, Max Planck Institute for Solid State Research, LESLIE SCHOOP, Department of Chemistry, Princeton University — We study the electronic structure of the nodal line semimetal ZrSiTe both experimentally and theoretically. We find two different surface states in ZrSiTe - topological drumhead surface states and trivial floating band surface states, which can be easily distinguished in ARPES experiments. Using the spectra of Wilson loops, we show that a non-trivial Berry phase that exist in a confined region within the Brillouin Zone gives rise to the topological drumhead-type surface states. The \( Z_2 \) structure of the Berry phase induces a \( Z_2 \) 'modular arithmetic' of the surface states, allowing surface states deriving from different nodal lines to hybridize and gap out, which can be probed by a set of Wilson loops. Our findings are confirmed by \textit{ab-initio} calculations and angle-resolved photoemission experiments, which are in excellent agreement with each other and the topological analysis.

10:36AM F60.00012: NMR investigation of topological quantum material ZrTe\textsubscript{5}*  YEFAN TIAN (Presenter), NADER GHASSEMI, JOSEPH HANSBRO ROSS, Department of Physics and Astronomy, Texas A&M University — In this work, we performed \(^{125}\text{Te}\) NMR measurements on the topological quantum material ZrTe\textsubscript{5}. The measured spin-lattice relaxation rates (1/\( T_1 \)) can be well-explained by a theoretical model for Dirac electron systems, which reveals that the topological characteristic of ZrTe\textsubscript{5} is \( T \)-dependent. Combined with DFT calculations, the topological transition ordering can be confirmed from weak topological state to strong topological state with temperature increasing, the reverse of what has been proposed. The \( T \)-dependence of Dirac band gap can be derived from NMR results, demonstrating a gapless Dirac semimetal state occurring at a Lifshitz transition temperature, \( T_c = 85 \) K in our crystals. We also show that the changes in NMR shift at the Lifshitz transition provide direct evidence of band inversion when the topological phase transition occurs.

*This work was supported by the Robert A. Welch Foundation, Grant No. A-1526.
Recent work has shown evidence of ferromagnetic order at room temperature in epitaxial single layer VSe$_2$, providing promising opportunities for emergent properties particularly when integrated with other 2D materials. In this work, we report the results of the heteroepitaxial growth of VSe$_2$ on epitaxial graphene/6H-SiC(0001) and topological insulator Bi$_2$Se$_3$. Using in situ scanning tunneling microscopy, we find markedly different growth behaviors on these two substrates. On top of graphene, hexagonal VSe$_2$ islands first nucleate randomly within the terraces, and then coalesce to form single layer VSe$_2$ upon further growth. In contrast, the epitaxial Bi$_2$Se$_3$(111) substrate surface exhibits spirals with atomically smooth terraces up to 50 nm in width. Here, the VSe$_2$ epilayer preferentially nucleates at the Bi$_2$Se$_3$ spiral step edges forming a distinct lateral Bi$_2$Se$_3$-VSe$_2$ heterojunctions. This growth mode of VSe$_2$ on Bi$_2$Se$_3$ provides unique opportunities to explore one-dimensional topological-magnetic heterostructures whose structural and electronic properties will be discussed at the meeting.

Tuesday, March 3, 2020 8:00 AM - 10:36 AM

Session F61 DMP DCMP DCOMP: Fe-Based Superconductors - Inhomogeneous Order Parameter  Mile High Ballroom 4B - Elena Gati, Ames Lab - Tag(s): Focus
8:00AM F61.00001: A strongly inhomogeneous superfluid in an iron-based superconductor*

[Invited] MILAN ALLAN (Presenter), Leiden University — Although the possibility of spatial variations in the superfluid of unconventional, strongly correlated superconductors has been suggested, it is not known whether such inhomogeneities—if they exist—are driven by disorder, strong scattering or other factors. In this seminar, I will present our recent atomic-resolution Josephson scanning tunneling microscopy study that reveal a strongly inhomogeneous superfluid in an iron-based superconductor. By simultaneously measuring the topographic and electronic properties, we find that the inhomogeneity in the order parameter is not caused by structural disorder or strong inter-pocket scattering, and does not correlate with variations in the energy of the Cooper pair-breaking gap. Instead, we see a clear spatial correlation between the order parameter and the quasiparticle strength, defined as the height of the coherence peak, on a local scale. This result places iron-based superconductors on equal footing with copper oxide superconductors, where a similar relation has been observed on the macroscopic scale. When repeated at different temperatures, our technique could further help elucidate what local and global mechanisms limit the critical temperature in unconventional superconductors. Time permitting, I will further discuss our recent atomic-scale noise spectroscopy studies in conventional and unconventional superconductors [2,3].

*We acknowledge funding from a ERC Starting Grant and NWO.

8:36AM F61.00002: Superconducting Fluctuations and Pairing Enhancement in Ultra-Thin FeSe/SrTiO3

BRENDAN FAETH (Presenter), Cornell University, SHUOLONG YANG, University of Chicago, JASON KAWASAKI, Materials Science, University of Wisconsin-Madison, JOCIENNE NELSON, PRAMITA MISHRA, Cornell University, CHEN LI, Cal Tech, DARRELL SCHLOM, KYLE M SHEN, Cornell University — A central challenge in understanding the Tc enhancement mechanism in FeSe/SrTiO3 monolayer films has been to decouple the myriad effects that the underlying substrate imposes on the superconductivity. Alkali surface-dosed multilayer films provide a natural comparison where the heavily electron-doped superconducting layer is constrained to the film-vacuum interface, analogous to the monolayer FeSe/STO interface but lacking any STO phonon contribution. To better understand the influence of the STO phonon contribution, we systematically explore the evolution of superconductivity as measured unambiguously by in situ electrical resistivity under varied conditions of film thickness, surface doping concentration, and substrate interface condition. In contrast to observations from spectroscopic probes which indicate a substantial enhancement in the pairing Tc, we observe only modest discrepancies in the zero-resistance temperature for surface doped layers in comparison to monolayer films. We demonstrate that this behavior is due to the shared influence of 2D fluctuation effects which act to suppress the resistive transition well below the cooper pair formation temperature, and discuss the implications of our results on the broader understanding of the FeSe/STO enhancement phenomenology.
8:48AM F61.00003: Nonlocal Correlations in Iron Pnictides and Chalcogenides

KRISTOFER BJORNSON (Presenter), Niels Bohr Institute, SHINIBALI BHATTACHARYYA, University of Florida, KARIM ZANTOUT, Goethe-Universität Frankfurt, ANDREAS KREISEL, Universität Leipzig, ROSER VALENTI, Goethe-Universität Frankfurt, BRIAN M ANDERSEN, Niels Bohr Institute, PETER HIRSCHFELD, University of Florida — Deviations of low-energy electronic structure of iron-based superconductors from density functional theory predictions have been parameterized in terms of band-dependent mass renormalizations and energy shifts. Theoretically, these have typically been described either in terms of a local self-energy within the framework of Dynamical Mean Field Theory, or in terms of nonlocal effects due to interband scattering. By calculating the renormalized bandstructure in both random phase approximation and the two-particle self-consistent approximation, we show that correlations in pnictide systems like LaFeAsO and LiFeAs can be described rather well by nonlocal correlations. In particular, Fermi pocket shrinkage as seen in experiment occurs along the paradigm of interband scattering scenario. We also show agreement with experimentally observed non-local scattering lifetime data for LiFeAs. Next, we compare with the canonical iron chalcogenide system FeSe in its bulk tetragonal phase, and show that band renormalizations are completely inconsistent with this picture. We discuss possible reasons for this discrepancy.

9:00AM F61.00004: Tunable impurity states in the unconventional superconductor FeTe$_{0.55}$Se$_{0.45}$

DAMIANOS CHATZOPOULOS (Presenter), DOOHEE CHO, KOEN M BASTIAANS, Leiden University, GENDA GU, Brookhaven National Laboratory, MILAN P. ALLAN, Leiden University — When a single impurity interacts with an unconventional superconductor, localized bound states appear inside its superconducting gap. Interestingly, these states can be used as a tool to bring insight into the electronic states of the material at stake. In this study, we use a low temperature scanning tunneling microscope operating at ultra-high vacuum, to find impurity states in the iron-based unconventional superconductor FeTe$_{0.55}$Se$_{0.45}$ ($T_c$=14.5 K). In order to enhance the energy resolution, a superconducting tip (Pb-coated) was employed. We find that the energy of the states shifts spatially and can be tuned by changing the distance between the sample and our scanning probe at the impurity site. In this talk I will discuss possible mechanisms that can lead to this dispersive behavior of the impurity energy state in space.

*Leiden University, NWO, NanoFront, ERC
9:12AM F61.00005: k\textsubscript{z} selective scattering within Quasiparticle Interference measurements of FeSe\textsuperscript{*} LUKE RHODES (Presenter), Royal Holloway Univ of London, MATTHEW D. WATSON, University of St Andrews, TIMUR KIM, Diamond Light Source, MATTHIAS ESCHRIG, University of Greifswald — Quasiparticle interference (QPI) provides a wealth of information relating to the electronic structure of a material. However, it is often assumed that this information is constrained to two-dimensional electronic states. Here, we show that this is not necessarily the case. For FeSe, a system dominated by surface defects, we show that it is actually all electronic states with negligible group velocity in the \textit{z}-axis that are contained within the experimental data. By using a three-dimensional tight-binding model of FeSe, fit to photoemission measurements, we directly reproduce the experimental QPI scattering dispersion, within a T-matrix formalism, by including both \(k_z = 0\) and \(k_z = \pi\) electronic states. This result unifies both tunnelling and photoemission based experiments on FeSe and highlights the importance of \(k_z\) within surface-sensitive measurements of QPI.

\*LCR is funded by an 1851 Early Career Research Fellowship.

9:24AM F61.00006: STM studies on FeSe\textsubscript{x}Te\textsubscript{1-x} thin films grown on Bi\textsubscript{2}Te\textsubscript{3} single crystal\textsuperscript{†}

GUANNAN CHEN (Presenter), LIN JIAO, JORGE OLIVARES RODRIGUEZ, ANUVA AISHWARYA, University of Illinois at Urbana-Champaign, LIANYANG DONG, STEPHEN WILSON, Materials Department, University of California, Santa Barbara, VIDYA MADHAVAN, University of Illinois at Urbana-Champaign — The iron-based superconductor FeSe\textsubscript{x}Te\textsubscript{1-x} has attracted intensive interest for the fundamental understanding of unconventional superconductivity. Here we report nanoscale studies on FeSe\textsubscript{x}Te\textsubscript{1-x} films on Bi\textsubscript{2}Te\textsubscript{3} single crystal. Three different kinds of heterostructures: fully embedded monolayer; half-embedded monolayer; and top monolayer were studied systematically using Scanning Tunneling Microscopy/Spectroscopy (STM/STS). The studies show different superconducting behaviors for the three different monolayers. In the half-embedded monolayer, we find an identical statistical distribution of superconducting gaps with similar gap size values to the ones in the bulk. Furthermore, on Bi\textsubscript{2}Te\textsubscript{3} surface, a proximitized gap is observed with a uniform distribution. If time permits, we will present our measurements of Fourier transform quasiparticle interference (QPI) for studying the order parameter.

Visualization of impurity-induced magnetism in FeSe using scanning tunneling microscopy

SANG YONG SONG (Presenter), JUNGPIL SEO, Daegu Gyeongbuk Institute of Science and Technology — High temperature superconductivity (HTSC) is typically found in the vicinity of the magnetic ordering. As the magnetic ordering is reduced by various means including chemical doping, intercalation and applying pressure, spin fluctuations (SF) emerge which are believed to mediate the Cooper pairing between electrons. Therefore, understanding of emergence of magnetism in HTSC is one of the fundamental keys to reveal the secret of the unconventional superconductivity. For most iron-based superconductors, the parent state of materials shows stripe antiferromagnetic (AFM) ordering which breaks the C4 symmetry of the lattice. However, such long range magnetism is absent in FeSe which has been one of mysteries in iron-based superconductors. Recently, theories suggest FeSe is close to the magnetic quantum critical point and thus weak impurities could induce local magnetism in FeSe. Here, we show the local magnetism is directly induced by impurities of FeSe using scanning tunneling microscopy (STM). More interestingly, the induced magnetism was consistent with the (pi,0) magnetic ordering, showing that this material falls into the category of Hund's metal in which orbital selectivity plays an important role.

High-field superconducting phase in FeSe investigated by spectroscopic-imaging scanning tunneling microscopy

TETSUO HANAGURI (Presenter), TADASHI MACHIDA, RIKEN CEMS, YUKI SATO, SHIGERU KASAHARA, Dept. Phys., Kyoto Univ., TAKASADA SHIBAUCHI, Dept. Adv. Mat. Sci., Univ. Tokyo, YUJI MATSUDA, Dept. Phys., Kyoto Univ. — The iron-based superconductor FeSe is characterized by its small Fermi energy that is only several times larger than the superconducting gap amplitude. In such a situation, so-called Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state with periodic nodal planes in the order parameter is expected near the upper critical field at low temperatures. In FeSe, magnetic-field dependence of thermal conductivity exhibits a cusp-like anomaly below the upper critical field, which is argued as a signature of the transition from the low-field normal vortex state to the high-field FFLO state [1]. We performed high-field spectroscopic-imaging scanning tunneling microscopy at an ultra-low temperature below 90 mK to investigate the change in the electronic state across the phase boundary. We found that the vortex image diminishes at about 14 T where the thermal conductivity shows a cusp. This result suggests that the nodal plane is pinned at the surface, if the high-field phase is an FFLO state. [1] S. Kasahara et al., Proc. Natl. Acad. Sci. U.S.A. 111, 16309 (2014).

10:00AM F61.00009: Probing antiferromagnetic order of iron-based superconductors through the surface*  ZHUOZHI GE (Presenter), QIANG ZOU, MINGMING FU, SHIVANI RAJPUT, Center for Nanophase Materials Sciences, Oak Ridge National Lab, LIURUKARA D SANJEEWA, ATHENA S. SEFAT, Materials Science & Technology Division, Oak Ridge National Laboratory, LIAN LI, Department of Physics and Astronomy, West Virginia University, ZHENG GAI, Center for Nanophase Materials Sciences, Oak Ridge National Lab — Understanding the surface structural and electronic properties of iron-based superconductors (FeSCs) is of great significance, as it can reveal the bulk superconducting properties. Previous study reveals a state near 0.2eV below Fermi level on √2×√2 or 2×1 reconstructed surface of Ba(Fe1-xCox)2As2, which is identified as a surface state by ARPES and DFT calculations. This state has also been observed on the surfaces of other 122 FeSCs with different doping levels, alkaline earth metal elements, and surface reconstructions. Its common presence suggests an origin other than simple surface state. Here, we systematically investigated low-temperature cleaved parent and slightly doped BaFe2As2 superconductors by scanning tunneling microscopy/spectroscopy (STM/S). We observed the same state on all √2×√2, 2×1 and even mixed surfaces. However, it vanishes when heating the sample above the Neel temperature (TN), and recovers after cooling down below TN, suggesting it is related to the bulk antiferromagnetic order.

*This research was conducted at the Center for Nanophase Materials Sciences, which is a DOE Office of Science User Facility. Z.Ge, L.S. and A.S.’s research are supported by the U.S. DOE, Office of Science, Basic Energy Sciences, Materials Science and Engineering Division.

10:12AM F61.00010: Investigation of the FeSe/SrTiO3 interface using Atom Probe Tomography*  SAMANTHA O’SULLIVAN (Presenter), RUIZHE KANG, CHRISTIAN MATT, JASON HOFFMAN, JENNIFER E. HOFFMAN, Harvard University — Monolayer FeSe on SrTiO3 (FeSe/STO) is a high temperature superconductor with Tc above 100 K. Although scanning tunneling microscopy (STM) imaging has characterized its surface in detail, the content and behavior in the FeSe/STO interface remains unclear. Characterizing the interface is important to gain further understanding on the mechanism for the unexpected high-temperature superconductivity in this system. Techniques such as scanning transmission electron microscopy (STEM) have been used to demonstrate that the interface structure is correlated with the material’s superconducting properties, however much remains unclear about the specific composition and behavior of the interface. Here we characterize the interface using atom probe tomography (APT), which reveals the structural and chemical properties of the FeSe/STO interface and provides insight into the origin of the material’s superconductivity.

*This work supported by the Gordon and Betty Moore Foundation’s EPiQS Initiative through Grant GBMF4536, the STC Center for Integrated Quantum Materials, NSF Grant DMR-1231319, and Office of Naval Research, Grant N00014-18-1-2691.
10:24AM F61.00011: Imaging Nematic Transitions in Iron-Pnictide Superconductors with a Quantum Gas*  
FAN YANG, STEPHEN TAYLOR (Presenter), STEPHEN D EDKINS, JOHANNA PALMSTROM, IAN FISHER, BENJAMIN L LEV, Stanford Univ — The SQCRAMscope is a recently realized Scanning Quantum CRyogenic Atom Microscope that utilizes an atomic Bose-Einstein condensate to measure magnetic fields emanating from solid-state samples. Here, we combine the SQCRAMscope with an in situ microscope that measures optical birefringence near the surface of a sample to study iron-pnictide superconductors, where the relationship between electronic and structural symmetry-breaking resulting in a nematic phase is under debate. We conduct simultaneous and spatially resolved measurements of both bulk and surface manifestations of nematicity via transport and structural deformation channels, respectively. By performing the first local measurement of emergent resistivity anisotropy in iron pnictides, we observe a spatially inhomogeneous increase in the temperature at which optical birefringence appears near the surface over that at which anisotropic local transport appears within the bulk. This is consistent with the existence of a higher-temperature surface nematic transition, albeit one that emerges inhomogeneously. More broadly, these measurements demonstrate the SQCRAMscope's ability to reveal important insights into the physics of complex quantum materials.

*Supported in part by ONR and DOE.

F61.00012: Manipulating superconductivity of monolayer FeSe on graphene/SiC(0001) surface  
WAN-TONG HUANG, HAICHENG LIN, CHENG ZHENG, YUGUO YIN, XINQIANG CAI, SHUAI-HUA JI (Presenter), XI CHEN, Tsinghua University — Compared with those of bulk FeSe, the sizes of electron and hole pockets become smaller in monolayer FeSe because the absence of inter-layer coupling tends to narrow the energy band and decrease the overlap between electron and hole pockets in energy. For FeSe monolayer grown on graphene/SiC(0001) surface, we find the Fermi energy is in the range of a few meV. In addition, we demonstrate an approach to tuning the Fermi energy by the thickness of graphene layers. At the base temperature of STM, the film grown on trilayer graphene becomes superconducting with Δ=0.62meV. In contrast, no signature of superconductivity has been detected in the dI/dV spectra of FeSe monolayer on bilayer graphene. The FeSe monolayer on graphene/SiC(0001) has the potential to study the intriguing physics where the Fermi energy, the superconducting gap and the Zeeman energy in magnetic field are in the same order of magnitude.

Session F62 DMP: Nanostructures and Metamaterials IV  
Igal Brener, Sandia National Laboratories
8:00AM F62.00001: Engineering quantum light emission from color-centers in atomically thin crystals with phase gradient metasurfaces. PANKAJ JHA (Presenter), GHAZALEH KAFAIE SHIRMANESH, HAMIDREZA AKBARI, MEIR GRAJOWER, BENJAMIN VEST, HARRY ATWATER, Caltech — Single-photon sources are elementary building blocks for photonic quantum technologies. However, progress in photonic quantum technologies has been constrained due to a lack of suitable materials with desired optical properties and the challenges in achieving coherent light-matter interaction at the quantum level. Here, we report a new approach for building chip-scale quantum hardware with color-centers in wide bandgap materials, such as hexagonal boron nitride (hBN), interfaced with planar arrays of classical nanoantennas, also known as metasurfaces. We investigated both exfoliated and chemical vapor grown hBN samples at room temperature. We performed photon-photon correlation measurements to isolate centers with single-photon emission characteristics and designed a phase gradient metasurface such that the emission from these color-centers can be efficiently extracted as well as redirected along a preferred direction. Our approach of interfacing these bright emitters with photonic metasurfaces and manipulating their emission characteristics would enable new opportunities for on-chip quantum photonics.

8:12AM F62.00002: Modeling NV charge stability in nanodiamonds with DFT CLAIRE MEARA (Presenter), PATRICK BRIDDON, MARK RAYSON, JONATHAN GOSS, Univ of Newcastle — The nitrogen-vacancy (NV) defect in diamond is a controllable quantum system with strong fluorescence. When placed in nanodiamonds it provides nanoscale magnetometry and single biological cell tracking[1]. NV must be stable and negatively charged close to the nanodiamond surface. However, NV charge-state fluctuations near surfaces result in intermittent fluorescence; this effect is highly correlated with surface type and structures[2]. Electron affinity has been posited as a cause, but contradictions exist and underlying mechanisms still need to be fully understood. Recent work shows NV charge alternates with pH[3], suggesting acceptor levels from surface radicals play a role. Using DFT the electronic structure of NVs in nanodiamonds is studied for different, commonly observed terminations, adsorbates and surface radicals. A measure of charge stability is defined and an underlying cause for observed charge instability for certain terminations is proposed. Routes to manipulating NV surfaces to provide stable NV- in nanodiamonds is discussed, thereby allowing more reliable spatiotemporal nanosensors.

Epsilon-near-zero modes in transdimensional planar plasmonic nanostructures*  IGOR BONDAREV (Presenter), HAMZE MOUSAVI, Math & Physics Dept, North Carolina Central Univ, VLADIMIR SHALAEV, ECE & Birck Nanotechnology Center, Purdue University — Transdimensional (TD) materials are ultrathin planar nanostructures composed of a precisely controlled finite number of monolayers[1]. Plasmonic TD materials offer advances such as controlled light confinement and thickness-controlled light-matter coupling that can further develop the fields of nanophotonics and metamaterials. We use quantum electrodynamics and the confinement-induced nonlocal dielectric response model based on the Keldysh-Rytova electron interaction potential to study the epsilon-near-zero modes (ENZ) of plasmonic films in the TD regime[2]. New remarkable effects are revealed. They are the plasmon mode degeneracy lifting and the dipole emitter coupling to the ENZ modes split. The latter leads to the thickness-controlled spontaneous decay with up to three-orders-of-magnitude increased rates. Knowledge of these features is advantageous both for the fundamental understanding of the electromagnetic properties and for the development of the new design principles of efficient photonic nanodevices with desired characteristics that are built on ultrathin metallic TD films. -- [1]A.Boltasseva & V.M.Shalaev, ACS Photonics 6, 1 (2019); [2]I.V.Bondarev, H.Mousavi, & V.M.Shalaev, arXiv1908.00640.

Plasmon Assisted Coherent Random Lasing*  DIPENDRA S KHATRI (Presenter), JIYANG CHEN, University of Memphis, YING LI, University of Nebraska-Lincoln, ELYAHB ALLIE KWIZERA, XIAOHUA HUANG, University of Memphis, CHRISTOS ARGYROPOULOS, University of Nebraska-Lincoln, THANG HOANG, University of Memphis — Random lasing occurs as the result of a coherent optical feedback from multiple scattering centers. Here, we demonstrate that plasmonic gold nanostars, through their small tips, are efficient light scattering centers which assist very narrow bandwidth and highly amplified coherent random lasing at a low lasing threshold. First, by embedding plasmonic gold nanostars in a rhodamine 6G dye gain medium, we observed a series of very narrow random lasing peaks with full-width at half-maximum (FWHM) ~0.8 nm. By contrast, free rhodamine 6G dye exhibited only a single lasing peak with FWHM of 6 nm. The lasing threshold for the dye with gold nanostars was two times smaller than that for a free dye. Further, by coating the tip of a single-mode fiber with these nanostars, we demonstrated the collection of the random lasing signal through the fiber that can easily be guided and analyzed. Time-resolved measurements showed a significant increase in the emission rate at above the lasing threshold, indicating a stimulated emission process.

8:48AM F62.00005: Photoluminescence quantum efficiency of nanowire quantum dots on silicon substrates  JIARONG CUI (Presenter), YIFEI WANG, HO VINH, VINH Q NGUYEN, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech — Nanowire quantum dots grown on silicon substrates provide promising technologies for integrating advanced photonic technologies on a silicon microelectronics. In this research our GaAsP nanowires contain GaAs quantum dot in the middle of the nanowires. We report the photoluminescence quantum efficiency as well as the thermal quenching mechanism of nanowire quantum dots prepared by vapor–liquid–solid method. We have performed high resolution spectroscopy, quantum yield, power dependence, and temperature dependence measurements of photoluminescence intensity from nanowire quantum dots. The data provide a picture of the quantum efficiency, thermal quenching processes and activation energy levels of nanowire quantum dots. The results provide an important step in the realization of nanowire quantum dots for photonic devices on silicon platform.

9:00AM F62.00006: Environmentally friendly core-shell quantum dots for light-emitting devices: A computational study*  MARIAMI RUSISHVILI (Presenter), University of Chicago, STEFAN WIPPERMANN, Max-Planck-Institute for Iron Research GmbH, DMITRI TALAPIN, GIULIA GALLI, University of Chicago — Semiconductor quantum dots (QDs) have been successfully used as light emitters in a variety of applications [1]. CdSe QDs exhibit the best performance in terms of tunable colors in the visible range and luminescence quantum yield. However, they contain a toxic heavy metal and the search for environmentally friendly nanostructured semiconductors is an active field of research. Recently InP based QDs have emerged as a promising alternative [2] to CdSe, although they exhibit broader emission spectra, possibly due to the sensitivity of their electronic structure to small morphological changes. Here we report on a first principle computational study of the structural and opto-electronic properties of InP/Zn(S/Se) core shell QDs. We used DFT with semi-local and hybrid functionals and the QuantumEspresso package (https://www.quantum-espresso.org/). We show that composition and interface morphology are key to achieve narrow emission lines, and we discuss the interplay between quantum confinement and strain in determining the electronic properties of these systems.

9:12AM F62.00007: Engineering thermochromic properties with plasmonics, quantum dots, and 2D materials. DONGHEON HA (Presenter), EVGHENI STRELCOV, IREAP, University of Maryland, STEVEN BLANKENSHIP, National Institute of Standards and Technology, AMIT AGRAWAL, IREAP, University of Maryland, ANDREI KOLMAKOV, NIKOLAI ZHITENEV, National Institute of Standards and Technology — For temperature-sensing applications, it is desirable to obtain strong thermochromic response in visible spectral range. We experimentally evaluate possible enhancements of sensitive thermochromic materials based on vanadium oxide (VO\textsubscript{x}) by nanophotonic engineering. First, we compare various growth methods, including a deposition and annealing of thin films and an electrochemical growth of single crystals. Second, we perform macro- and microscale temperature-dependent optical measurements of materials with different composition. Then, we demonstrate an enhanced thermochromic behavior by the application of plasmonic and quantum materials. With periodic gold hemispherical structures atop VO\textsubscript{2} crystals, the optical contrast at the VO\textsubscript{2} phase transition from semiconductor to metal is increased by \(\approx 15\)\% at visible/near-infrared wavelengths. The enhancement is due to the localized surface plasmon resonances of gold particles and can be described within the Maxwell-Garnett effective medium theory. We also discuss other approaches, including the coupling of two dimensional materials and colloidal quantum dots, to further tailor temperature-dependent optical response of thermochromic materials. Finally, we introduce possible applications focusing on nanoscale temperature sensing.

9:24AM F62.00008: Surface functionalization of nanoparticles for fabrication of size-tunable and electrochemically actuable nanostructured shell assembly* MARK BARTOLO (Presenter), Materials and Biomaterials Science and Engineering, University of California, Merced, RYAN BRISBIN, RYAN BAXTER, Chemistry and Chemical Biology, University of California Merced, SAYANTANI GHOSH, Physics, University of California Merced — Surface modification of quantum dots (QDs) is one of the most versatile methods of customizing their optical and electronic properties. Our goal is to leverage surface functionalization of CdSe/ZnS QDs for optimal directed assembly to be utilized in biological and biomedical cargo delivery systems. We have developed nano-assembled micro-shell structures composed of gold nanoparticles functionalized with custom-designed ligands\textsuperscript{1} which allowed plasmonic actuation. Here, we focus on Bis(Imino)Pyradine (BIP) ligands which have improved thermal stability, optical properties, and biocompatibility of the shell structures, while allowing cargo release via electrochemical stimulation. In addition, the versatility of the BIP ligands have made it possible for us to tune the shell diameter from 200 nm to 1 micron, which vastly broadens the field of applications. In this study we present a systematic characterization of the QD surface chemistry to observe and understand correlations between QD diameter, ligand size and shell size.

*This research was supported by NSF CREST grant no. HRD-1547848
9:36AM F62.00009: Transition to strong coupling regime for quantum emitters near a plasmonic nanostructures  
TIGRAN SHAHBAZYAN (Presenter), Jackson State Univ — We present a model for exciton-plasmon coupling based on energy exchange mechanism between quantum emitters (QE) and localized surface plasmons in metal-dielectric structures. Plasmonic correlations between QEs give rise to a collective state exchanging its energy cooperatively with a resonant plasmon mode. By defining carefully the plasmon mode volume for a QE ensemble, we obtain a relation between the QE-plasmon coupling and the cooperative energy transfer rate that is expressed in terms of local fields. For a single QE near a sharp metal tip, we find analytically the enhancement factor for the QE-plasmon coupling relative to the QE coupling to a cavity mode. For QEs distributed in an extended region enclosing a plasmonic structure, we find that the ensemble QE-plasmon coupling saturates to a universal value independent on system size and shape, consistent with the experiment.

9:48AM F62.00010: Tip-controlled Strong Coupling with Infrared Polaritonic Heterostructures  
SAMUEL C. JOHNSON (Presenter), University of Colorado Boulder, NISHANT NOOKALA, Department of Electrical & Computer Engineering, The University of Texas at Austin, MIKHAIL A. BELKIN, Walter Schottky Institute and ECE Department, Technical University of Munich, MARKUS B. RASCHKE, University of Colorado Boulder — Infrared polaritonic metasurfaces based on a multi-quantum-well intersubband transition coupled to a gold antenna heterostructure exhibit record-high nonlinear optical responses and optical power limiting behavior. However, these structures are limited to passive performance depending on fabrication parameters. Here, we use infrared scattering scanning near-field optical microscopy to image single antenna quantum well heterostructures, and to actively tune quantum-well saturation, coupling strength, and quantum path interference through manipulation of the nanocavity mode volume through tip-sample distance control. Further, the AFM tip as a coupled antenna resonator is used to enhance far-field coupling to control photon emission, field orientation, and nanoscopic field heterogeneity. Previous picosecond laser far-field optical power limiting and pump-probe characterization is extended with near-field spectroscopy, using femtosecond laser, picosecond laser, and synchrotron infrared light sources.
10:00AM F62.00011: Active Tuning of Phonons and Surface-Phonon Polariton Resonances
ADAM DUNKELBERGER (Presenter), CHASE ELLIS, DANIEL RATCHFORD, ALEXANDER GILES, D. SCOTT KATZER, United States Naval Research Laboratory, ANDREA GRAFTON, VANESSA BRESLIN, ELIZABETH RYLAND, NRC RAP Postdoctoral Fellow, MIJIN KIM, KeyW Corp, CHUL SOO KIM, IGOR VURGAFTMAN, JOSEPH G TISCHLER, JEFFREY OWRUTSKY, United States Naval Research Laboratory, JOSHUA D CALDWELL, Vanderbilt University — The infrared spectra of many polar semiconductors are dominated by highly reflective reststrahlen bands that occur between the transverse and longitudinal optical phonons. Through the LOPC effect, free carriers shift the reststrahlen band to higher frequencies. We have previously shown that photoinjected carriers transiently and reversibly modify the infrared reflectivity of bulk SiC. Within the reststrahlen band, SiC and InP nanostructures can exhibit surface-phonon polariton resonances. Here we report, for the first time, active tuning of SiC and InP surface-phonon polariton resonances via carrier photoinjection, achieving better modulation depths than active tuning in plasmonic systems. In SiC, ultraviolet excitation with femtosecond laser pulses induces $>10$ cm$^{-1}$ shifts in the transverse dipole resonance (width = 7 cm$^{-1}$). Time-resolved infrared reflection spectroscopy reveals that the photoinduced shifts decay in tens of ps, depending on the initial carrier density. Our results suggest that spatial redistribution of photoexcited carriers dominates the time dependence of the active tuning. We also report, for the first time, direct time-resolved infrared spectroscopy of the LO mode of GaN, made experimentally accessible through the Berreman effect.

10:12AM F62.00012: Excitation of non-radiating anapoles in dielectric nanospheres*
UTTAM MANNA (Presenter), Illinois State University, JOHN A. PARKER, University of Chicago, HIROSHI SUGIMOTO, Kobe University, BRIGHTON COE, DANIEL EGGENA, Illinois State University, MINORU FUJII, Kobe University, NORBERT F. SCHERER, University of Chicago, STEPHEN K GRAY, Argonne National Laboratory — Nonradiating anapoles are superposition of internal modes that can act as an energy reservoir by reducing the far-field scattering. We report experimental excitation of the electrodynamic anapole mode in isotropic silicon nanospheres at the optical frequencies using radially polarized beam illumination. The superposition of equal and out-of-phase amplitudes of the Cartesian electric and toroidal dipoles produces a pronounced dip in the scattering spectra with the scattering intensity almost reaching zero – a signature of anapole excitation. The total scattering intensity associated with the anapole excitation is found to be more than 10 times weaker, and the internal energy is found to be 6 times greater for illumination with radially vs. linearly polarized beams. Our approach provides a simple, straightforward alternative path to realize electrodynamic anapole mode at the optical frequencies.

*This material is based upon work supported by the National Science Foundation (NSF) under Grant No. ECCS-1809410. H.S. and M. F. acknowledge KAKENHI grant numbers 18K14092 and 18KK0141.
Tailoring the chiro-optical response of Si-Ag/Au chiral heterostructure thin films fabricated by glancing angle deposition technique

UFUK KILIC (Presenter), MATHEW HILFIKER, Electrical and Computer Engineering Department, University of Nebraska - Lincoln, RENE FEDER, The Fraunhofer Institute for Microstructure of Materials and Systems (IMWS), RAFAL KORLACKI, EVA SCHUBERT, CHRISTOS ARGYROPOULOS, MATHIAS SCHUBERT, Electrical and Computer Engineering Department, University of Nebraska - Lincoln — Chiro-optical response of subwavelength scale nanostructures have been the subject of many research projects such as bio-sensors, topological insulators, and photonic integrated circuit designs. [1] In this study, by using glancing angle deposition technique, subsequent and repeated depositions of silicon(Si) and gold(Au)/silver(Ag) lead to nanometer-dimension sub-chiral segments, and thus, we successfully fabricated spatially coherent, highly porous, super lattice type chiral heterostructure (CHS) thin films. We incorporated the transmission mode Mueller matrix spectroscopic ellipsometry technique with finite element modeling environment in order to investigate the chiro-optical properties of this new type plasmonic metamaterials. Interestingly, Au/Ag sub-chiral segments in CHS result in the emergence of multiple plasmonic modes which can be tunable depending on the Au/Ag-Si ratio in a single turn. Unlike the other studies [2,3] which employs periodic nanostructures made up of single type material, we observed extraordinary optical activity in our fabricated CHS thin films.

10:36AM F62.00014: STM Characterization of hBN-Decoupled Covalent Organic Frameworks* DANIEL RIZZO (Presenter), University of California, Berkeley, QINGQING DAI, Georgia Institute of Technology, CHRISTOPHER BRONNER, GREGORY VEBER, University of California, Berkeley, BRIAN J SMITH, Bucknell University, MICHIO MATSUMOTO, Northwestern University, SIMIL THOMAS, Georgia Institute of Technology, GIANG DUC NGUYEN, PATRICK R FORRESTER, WILLIAM ZHAO, JAKOB H JORGENSEN, University of California, Berkeley, WILLIAM DICHTEL, Northwestern University, FELIX FISCHER, University of California, Berkeley, HONG LI, JEAN-LUC E BREDAS, Georgia Institute of Technology, MICHAEL F CROMMIE, University of California, Berkeley — Covalent organic frameworks (COFs) are crystalline molecular networks with potential applications in filtration, organic electronics, energy storage, and catalysis. Recent advances in COF synthesis have permitted the growth and characterization of COFs that exhibit different symmetries and that use a wide range of molecular building blocks. Despite this progress, there have only been a limited number of experimental demonstrations of the electronic structure-function relationship for COFs, particularly in the 2D limit. One experimental challenge is how to separate the intrinsic COF electronic structure from the influence of metallic growth substrates. In order to accomplish this, we have introduced an atomic insulating film of hBN between a COF and an underlying metallic substrate to act as a decoupling layer. Using scanning tunneling microscopy and spectroscopy we are able to obtain more detailed spectral information on hBN-decoupled COFs compared to those grown directly on a metallic substrate. First-principles DFT and tight-binding calculations confirm that hBN-decoupled COFs possess spectral features that reflect the COF's Kagome lattice symmetry.

F62.00015: Strain Effect on Silicene Quantum Dot Embedded in Silicane* BI-RU WU (Presenter), Chang Gung Univ — A new design for silicene quantum dots (SiQDs) embedded in silicane probably makes magnetism and band gap of the SiQD being controllable by hydrogen. In this paper, the strain effect for the embedded SiQD in silicane was investigated by a first-principles method. The homogeneous strain and two types of uniaxial strains are considered. As expected, the band gap can be tuned by strains and the behavior of the band gap are distinct while applied with different strain types. However, the magnetism is still determined by the size and shape of the SiQD. Strain cannot alter the magnetism of the embedded SiQD. The variation of band gap of various shapes of embedded SiQD also have different behaviors under strains.

8:00AM F63.00001: Temperature and Phase Dependence of Carrier Diffusion in Single Crystal MAPbI₃ Perovskite Microstructures* LUKE MCCLINTOCK (Presenter), RUI XIAO, YASEN HOU, HENRY TRAVAGLINI, University of California, Davis, DAVID ABRAMOVITCH, University of California, Berkeley, LIANG TAN, Lawrence Berkeley National Laboratory, DONG YU, University of California, Davis — Understanding and improving carrier transport in photovoltaic materials is crucial to developing high quality solar energy harvesting devices. Here, we have investigated carrier diffusion lengths in single crystal methylammonium lead iodide (MAPbI₃) microstructures via scanning photocurrent microscopy. Carrier diffusion lengths were found to increase abruptly once below the transition temperature from the tetragonal to the orthorhombic phase and reached 200 ± 50 μm at 80 K. Enormous mobility values of 3 x 10⁴ cm² / V s were extracted at 80 K using these long diffusion lengths in combination with transient photocurrent lifetime measurements. We attributed the increased diffusion lengths to the emergence of an excitonic nature to the transport in the orthorhombic phase. Our findings provide significant fundamental insights on the temperature and phase-dependent charge transport properties of halide perovskites.

8:12AM F63.00002: Quantifying exciton heterogeneities in mixed-phase organometal halide multiple quantum wells via Stark spectroscopy studies ERIC AMERLING (Presenter), SANGITA BANIYA, Chemistry, University of Utah, EVAN LAFALCE, Physics, University of Utah, STEVE BLAIR, Electrical Engineering, University of Utah, ZEEV VALY VARDENY, Physics, University of Utah, LUISA WHITTAKER-BROOKS, Chemistry, University of Utah — Solution processable organic-inorganic hybrid perovskite (OIHP) quantum wells naturally self-assemble through weak van der Waals forces. In this study, we investigated the structural and optoelectronic properties of \((\text{C}_4\text{H}_9\text{NH}_3)_{2}(\text{CH}_3\text{NH}_3)_{n-1}\text{Pb}_{n}\text{I}_{3n+1}\), varying \(n\) from 1 to 4. Through conventional structural characterization, the thin films showcase high-quality phase purity. However, while investigating the optoelectronic properties, it was clear that these van der Waals heterostructures consist of multiple quantum well thicknesses coexisting within a single thin film. We utilized modulation spectroscopy, electroabsorption, and Liptay theory analysis to deconvolute the different excitonic features arising from different quantum well thicknesses (n). Rather than merely identifying what quantum well heterostructures are present within a thin film, this novel method of analysis provides powerful insight into the exact exciton composition in the thin film and can be utilized to analyze the optoelectronic properties of many other mixed-phase quantum well heterostructures beyond those formed by OIHPs.
8:24AM F63.00003: Angle-Resolved Time-Resolved Microwave Conductivity  SHIRSO PRATIM CHATTOPADHYAY (Presenter), Materials Science, Oregon State University, JOHN LABRAM, Electrical Engineering and Computer Science, Oregon State University — The contactless electronic characterization technique time resolved microwave conductivity (TRMC) provides a very convenient way of quickly evaluating carrier mobilities and lifetimes for a variety of semiconducting materials. However, the technique has one notable limitation in that it can conventionally only be used to resolve carrier mobilities in the plane of substrate (lateral mobility).

Here we present a novel approach for resolving charge carrier mobilities in different planes within a sample. Using a range of 3D-printed samples holders, where the sample is held at various angles relative to the incident light, we are able to resolve the mobility in the plane of the sample and out of the plane of the sample. Because charges generally travel in the direction perpendicular to the substrate in solar cells, identifying carrier mobility in this direction is particularly valuable. We studied the archetypical hybrid halide perovskite compound, methylammonium lead iodide. Our results show that for films prepared using our solution-processing route, mobilities in-plane are significantly higher than those out-of-plane.

8:36AM F63.00004: Peculiar Defects Behavior in Charge Recombination of Metal Halide Perovskites  WEIBIN CHU (Presenter), Univ of Southern California, WISSAM A SAIDI, Univ of Pittsburgh, JIN ZHAO, Univ of Science and Technology of China, OLEG PREZHD0, Univ of Southern California — Defects are inevitably introduced in the near room-temperature and solution-based growth of metal halide perovskites (MHPs) thin films for solar cell devices. However, the astonishing improvements in the efficiency of the corresponding solar cells indicate that MHPs have a strong defect tolerance. Motivated by the recent experimental demonstration of a new state-of-art β phase CsPbI$_3$ with a stable and impressive efficiency reaching 18.4% at ambient conditions, we investigate the non-radiative recombination processes in CsPbI$_3$ using ab initio non-adiabatic molecular dynamics within real-time time-dependent Kohn-Sham formalism and surface-hopping framework. Regardless of their nature, we find that the native defects in CsPbI$_3$ do not accelerate the charge recombination process. We show that the strong tolerance of electron-hole recombination against defects is explained due to the combination of having low-frequency lattice phonons and weakly overlapping electron and hole states. The deep-level defect becomes tolerant owing to the strong covalency, which contrary to predictions from SRH theory in previous work. Considering similar results found in MAPbI$_3$, we propose that the strong defect tolerance is general to the metal halide perovskites.
8:48AM F63.00005: Small Urbach energies in halide perovskites due to anharmonicity and short-range correlated disorder  
CHRISTIAN GEHRMANN (Presenter), DAVID A. EGGER,  
Department of Physics, TU Munich — Halide perovskites (HaPs), a class of up-and-coming solar absorber materials, feature small Urbach energies and sharp optical absorption edges. These characteristics render the fabrication of efficient HaP based solar-cell devices possible. But they also indicate a low amount of disorder, which is seemingly in contrast with the complex nuclear dynamics and structural effects known for HaPs. Here, we present our findings on spatial correlations in the disorder potential induced for electronic states due to nuclear dynamics in several HaPs. Our theoretical results are based on density functional theory (DFT) calculations and DFT-based molecular dynamics [1]. With this approach, anharmonicity in the nuclear dynamics is accounted for up to all orders in the Taylor expansion of the crystal potential. We find that correlations in the disorder potential are dynamically shortened. The mechanism responsible for this shortening is found to be the nuclear motion of A-site and X-site ions. We conclude that sharp optical absorption edges and small Urbach energies in HaPs are possible due to the dynamical shortening of correlations in the disorder potential.

9:00AM F63.00006: The evolution of ultrafast carrier dynamics in situ perovskite solar cells*  
EXIAN LIU (Presenter), Physics & Astronomy, Clemson University, JINHUI TONG, National Renewable Energy Laboratory, KANISHKA KOBBEKADUWA, PAN P ADHIKARI, Physics & Astronomy, Clemson University, KAI ZHU, National Renewable Energy Laboratory, JIANBO GAO, Physics & Astronomy, Clemson University — Photoelectric performances of perovskite solar cells (PSC), such as photovoltage, short-circuit current density, fill factor and power-conversation-efficiency are determined by the charge carrier dynamics, especially the early-stage processes including charge generation, recombination and interface transfer. These photophysics dynamics, which are within pico- to nano-second timescale, directly relate to the PSC working mechanism. However, the study on the ultrafast photophysics dynamics in situ PSC is still in infancy although considerable works were performed on the performance improvement at steady-state condition. 
Aim to elucidate ultrafast carrier dynamics in-situ PSC, in this talk, we present the carrier dynamics in-situ organic–inorganic halide perovskite solar cells utilizing ultrafast photocurrent spectroscopy with sub-40 picosecond time. We study the evolution of ultrafast carrier dynamics in situ perovskite solar cells, in term of the evolution of open-circuit voltage, short-circuit current, and fill factor, in addition to addressing the desirable fundamental questions including carrier lifetime, mobility, trap density, and carrier transport mechanisms.

*Clemson University
9:12AM F63.00007: Defects in polymorphous cubic halide perovskites: coexistence of shallow and deep vacancy transition levels*  
GUSTAVO DALPIAN (Presenter), Univ Federal do ABC, XINGANG ZHAO, ALEX ZUNGER, University of Colorado Boulder — Halide perovskites are usually said to be defect tolerant materials suggesting a possible explanation for being good solar compounds. Molecular dynamics (MD) simulations of Cohen et al revealed that the orbital energy of the Br-vacancy in CsPbBr\(_3\) resides deep in the gap (i.e., not defect tolerant) and can considerably fluctuate on the time scale of the MD trajectories. Recently, it was pointed out that the static structure of cubic halide perovskites involves a distribution of different local environments such as tilting and atomic displacements, being a polymorphous network [Zhao, X., Dalpian, G. M., Wang, Z. & Zunger, A. *The polymorphous nature of cubic halide perovskites.* arXiv:1905.09141 (2019)]. We have studied anion vacancies in different, inequivalent lattice sites in the polymorphous network of CsSnI\(_3\), CsPbI\(_3\), MaPbI\(_3\), and CsPbBr\(_3\), finding that all except CsPbBr\(_3\) have shallow transition levels whereas the latter has a bimodal distribution with some deep levels (mostly shallow). We show how these results correlate with the local geometric deformations of the various sites in the polymorphous network.

*Supported by NSF-DMREF, No. 1921949 and FAPESP.

9:24AM F63.00008: Hot Carrier Dynamics in Bulk and 2D Perovskites*  
SHASHI SOURABH (Presenter), VINCENT R. WHITESIDE, HAMIDREZA ESMAIELPOUR, BRANDON DURANT, Department of Physics and Astronomy, University of Oklahoma, GILES E. EPERON, MATTHEW C BEARD, National Renewable Energy Laboratory, IAN R SELLERS, Department of Physics and Astronomy, University of Oklahoma — A comparison of the effect of carrier-carrier and carrier-phonon interactions in 2D (BA)\(_2\)PbI\(_4\) Ruddlesden-Popper (n=1) and conventional bulk MAPbI\(_3\) perovskite thin films is presented. It is shown that the nature and strength of the exciton binding energy strongly mediate the nature of their interaction with phonons. Specifically, more strongly coupled excitons manifest themselves in the formation of small polarons that interact with lattice via the emission of LO-phonon replicas, while weakly bound (or free) excitons interact with phonons to form large polarons resulting in large LO-phonon broadening and strong carrier-phonon scattering. These results suggest that the unusual hot carrier thermalization observed in the perovskites is dominated by the strength and nature of the exciton-phonon interaction and subtelty different from more conventional semiconductors. To support this hypothesis, comparisons of the hot carrier dynamics and electron-phonon interaction in a number of stable and well-studied perovskites are also presented.

*Support is acknowledged through the Department of Energy ESPCoR program and the Office of Basic Energy Research, Materials Science and Energy Division under Award No.# DE-SC0019384
Unravelling free carrier and exciton dynamics in hybrid organic-inorganic perovskites using transient absorption spectroscopy  
CHANG QING (Presenter), DAMING ZHAO, Division of Physics and Applied Physics, School of Physical and Mathematical Sciences, Nanyang Tech Univ, HONGWEI HU, YENG MING LAM, School of Materials Science and Engineering, Nanyang Tech Univ, EE MIN CHIA, Division of Physics and Applied Physics, School of Physical and Mathematical Sciences, Nanyang Tech Univ — Mixed-cation lead mixed-halide perovskites have been shown to good photostability, thermal stability and high power conversion efficiency, proving to be good candidates as energy harvesting materials [1]. Transient absorption spectroscopy is a powerful tool to study the response of free carriers and excitons upon photoexcitation in the perovskites [2]. Here, we excite FA_{0.85}Cs_{0.15}PbI_{2.9}Br_{0.1} thin films with bandgap and above-bandgap pump pulses, and probe the sample with white light. Our results show that, compared to resonant excitation, shorter-wavelength excitation generates more free carriers, and by increasing the pump fluence, bandgap renormalization and hot-phonon bottleneck can be achieved.

Observation of large negative thermo-optic coefficients in lead halide perovskites*  
TAKETO HANDA (Presenter), HIROKAZU TAHARA, YOSHIHIKO KANEMITSU, Institute for Chemical Research, Kyoto University — Lead halide perovskites are a new class of semiconductor materials for photonic devices [1]. Despite intensive research in the last decade, some of their fundamental physical properties still remain unclear. Here, we report that the halide perovskite CH₃NH₃PbCl₃ shows a large negative thermo-optic coefficient, i.e., a distinct decrease of the refractive index upon temperature rise [2]. We demonstrate that this unique response provides new photonic applications [2,3]. Furthermore, the negative thermo-optic property indicates unusual thermally-induced changes in the electronic states. We investigated the origin of the negative coefficient through the temperature dependence of the absorption spectra of a CH₃NH₃PbCl₃ thin film. With increasing temperature, a slight blueshift in the absorption peak energy was observed. Our analysis suggests that both the absorption blueshift and large thermal expansion contribute to the large negative thermo-optic coefficients of halide perovskites.

10:00AM F63.00011: Breaking the Defect Bottleneck in Halide Perovskite Semiconductors

[Invited] ARON WALSH (Presenter), National Renewable Energy Laboratory — The physical properties of semiconducting solids depend on the imperfections they contain[1]. Defects come in a few flavours: conductivity-promoting defects create free carriers that enable electronics; killer defects (deep centres) trigger recombination; and charge scattering defects reduce mobility. Our understanding of halide perovskites is limited in comparison to inorganic semiconductors. I will discuss recent progress, from theory and experiment, to identify, characterise and control point defects and defect processes in this family of compounds. I will cover charge compensation mechanisms [2], carrier trapping phenomena[3], the effect of grain boundaries[4], and how this understanding can be applied to engineer defect populations and distributions. The use of `defect tolerance` as a metric to develop and screen post-perovskite materials will be critically addressed.

10:36AM F63.00012: Electrohydrodynamically Assisted Deposition of organo-metallic hybrid perovskite thin films for Photovoltaics applications*

ALBERT DIBENEDETTO (Presenter), WILLIAM DELMAS, SAYANTANI GHOSH, University of California, Merced — The creation of lightweight and high efficiency photovoltaic devices is challenging, especially for deployment under extreme conditions, such as in outer space. Deposition techniques like drop casting or spin coating produce nonuniform films and are only useful under the influence of gravity. We have developed an alternative technique to prepare thin films via electrohydrodynamically (EHD) assisted deposition. Using Marangoni flow, this process allows precursors of different vapor pressures to be guided (via an applied electric field) onto a substrate in order to self-organize and produce uniform thin films while minimizing the amount of waste solution. In this talk, we will present different perovskite solar cell prototypes with different space qualified substrates that were prepared via EHD assisted deposition. To compare each prototype, we use characterization using photoluminescence (PL), spectroscopy, scanning electron microscopy (SEM), and atomic force microscopy (AFM). As a final goal, we aim to develop and optimize perovskite solar cell prototypes from inks of high wettability and space qualified substrates.

*This grant was supported by NASA grant no. NNX15AQ01.
Two-dimensional (2D) perovskite solar cells that boast of high stability and high efficiency have attracted significant attention. A systematically static and dynamic structure investigation is carried out to show the details of 2D morphology evolution. A dual additive approach is applied, in which the synergic efforts of alkali metal cation and polar solvent lead to high quality 2D perovskite thin film with well orientation. The novel structure can induce high quality 2D slab growth as well as reduce internal and surface defects, thus resulting in a high device efficiency of 13.65%. Steady-state and transient absorption spectra reveal the carrier transporting from low n to high n species of different kinetics. An \([\text{PbI}_6]^{4-}\) octagon coalescence transformation mechanism coupled with metal and organic cations wrapped is proposed, which then subjects to solvent vapor annealing to recrystallize and reorient 2D perovskite slabs to form an ideal structure to give rise to the improvement of device efficiency and stability.
Advances in computing charge carrier dynamics in oxides from first principles* [Invited] JIN-JIAN ZHOU (Presenter), MARCO BERNARDI, Department of Applied Physics and Materials Science, California Institute of Technology — Advances in first-principles calculations enable accurate predictions of charge carrier mobility and scattering mechanisms in materials. However, many oxides remain an open problem for these methods since they exhibit soft phonon modes due to structural phase transitions and electron-phonon interactions strong enough to form polarons. The presence of polarons and soft modes makes first-principles calculations of charge transport highly challenging even in non-correlated oxides.

This talk will discuss new approaches for treating electron-phonon coupling due to soft phonon modes, as well as a cumulant diagram-resummation approach for rigorously computing the carrier mobility in the large polaron regime. We apply these approaches to cubic SrTiO$_3$ perovskite as a paradigmatic case and analyze in detail soft mode and polaron contributions to charge transport.

Our advances allow us to accurately predict the temperature dependence [1] and absolute value [2] of the mobility in SrTiO$_3$, while providing long-sought microscopic details about the scattering mechanisms, bandstructure renormalization and beyond-quasiparticle features in the spectral function due to the strong electron-phonon coupling. Efforts to extend these calculations to a range of oxides and future application of these approaches to interfaces and heterostructures will be discussed.

Superconducting split-gate quantum point contacts in ionic liquid-gated SrTiO₃

EVGENY MIKHEEV (Presenter), ILAN ROSEN, DAVID GOLDHABER-GORDON, Stanford Univ — SrTiO₃ is one of few materials to exhibit superconductivity at carrier densities low enough to be manipulated electrostatically. In this work, we demonstrate electrostatically defined superconducting devices that combine global ionic liquid gating of the leads with local dielectric split gates. This design enables patterning of a 2D electron system with sub-100 nm features without the need for mesa etching. When tuned into a normal state, these devices behave as ballistic quantum point contacts, with conductance quantization near pinch-off. Quantization is in increments of e²/h, even at zero magnetic field, suggesting spontaneous spin-polarization. When the device leads are tuned to be superconducting, the weak link can be gated through a sequence of transport regimes: pinch-off, coulomb blockade, superconducting tunnel junction, and SNS or SS'S Josephson junction. We demonstrate that the local constriction can be tuned into a regime where its critical field exceeds that of its superconducting leads. This offers promise of exploring the microscopic physics of underdoped SrTiO₃, where two-dimensional superconductivity is usually suppressed by the lack of macroscopic coherence.

Probing the superconductivity of ferroelectric SrTiO₃ films

TIMO SCHUMANN (Presenter), LUCA GALLETTI, KAVEH AHADI, HANBYEOL JEONG, SUSANNE STEMMER, University of California, Santa Barbara — We report on the superconducting characteristics of doped 180-nm-thick SrTiO₃ films, grown by molecular beam epitaxy on (001) LSAT substrates. The epitaxial compressive strain induced by the substrate stabilizes a ferroelectric phase in the SrTiO₃ for carrier concentrations ranging from 5×10¹⁹ – 1.5×10²⁰ cm⁻³ [1,2]. A systematic study of the critical temperature and critical field as a function of the carrier density and type of doping atom reveal deviations from those expected for a single-band BCS superconductor. In particular, the critical temperature and critical field show qualitative different evolutions, with the latter exceeding the Pauli limit for certain values. We discuss the role of the band structure and inversion symmetry breaking.

9:00AM F64.00004: Superconductivity and Antiferrodistortive Phase Transition in Sr\textsubscript{1-x} Nd\textsubscript{x} TiO\textsubscript{3} Films  
JIN YUE (Presenter), Department of Chemical Engineering and Materials Science, University of Minnesota, YILIKAL ZAYINO, MARIA NAVARRO GASTIASORO, School of Physics and Astronomy, University of Minnesota, EYLON PERSKY, ALEX HANUKOV, Department of Physics and Institute of Nanotechnology and Advanced Materials, Bar-Ilan University, Ramat Gan, Israel, TRISTAN TRUTTMANN, Department of Chemical Engineering and Materials Science, University of Minnesota, BEENA KALISKY, Department of Physics and Institute of Nanotechnology and Advanced Materials, Bar-Ilan University, Ramat Gan, Israel, RAFAEL FERNANDES, VLAD PRIBIAG, School of Physics and Astronomy, University of Minnesota, BHARAT JALAN, Department of Chemical Engineering and Materials Science, University of Minnesota — Despite over 60 years of extensive research, the study of superconductivity, ferroelectricity and antiferrodistortive phase transition in SrTiO\textsubscript{3} remains puzzling yet intriguing. Through intrinsic defect management, we achieved for the first time electron density as low as 3 \times 10^{17} \text{ cm}^{-3} in Sr\textsubscript{1-x} Nd\textsubscript{x} TiO\textsubscript{3} films with the corresponding mobility exceeding 42000 \text{ cm}^{2}/\text{vs} at 1.8 K. By systematically varying the carrier density over three orders of magnitude, we present an important role of intra- vs. inter-band scattering on the superconducting transition temperature \( T_c \) across the Lifshitz transition. Significantly, we show a sizable effect of the antiferrodistortive phase transition on the normal state transport properties around 110 K. Finally, we discuss the role of dopant concentration, strain and dimensionality on the interplay between antiferrodistortive phase transition, incipient ferroelectricity, and normal and superconducting transport behavior in epitaxial Sr\textsubscript{1-x}Nd\textsubscript{x}TiO\textsubscript{3} thin films grown by hybrid molecular beam epitaxy approach.

9:12AM F64.00005: Ferroelectric Control of Normal and Superconducting States in Oxide Interface by Intrinsic and Extrinsic Bias  
GAL TUVIA (Presenter), Tel Aviv University, YIFTACH FRENKEL, physics, Bar Ilan University, PRASANNA KUMAR ROUT, Delft University of Technology, ITAI SILBER, Tel Aviv University, BEENA KALISKY, physics, Bar Ilan University, YORAM DAGAN, Tel Aviv University — We deposit the polar oxide LaAlO\textsubscript{3} on Ca doped SrTiO\textsubscript{3} with various Ca concentrations. The latter becomes ferroelectric below 30K. The resulting interface is conducting with a critical thickness of 3 unit cells of LaAlO\textsubscript{3}. A large increase in the interface resistance is observed as the temperature is decreased below the ferroelectric transition with a strong hysteretic behavior as a function of gate voltage. Below \( T_c \) 300mK the sample becomes superconducting with a clear hysteresis in \( T_c \) with respect to the applied gate voltage. We use scanning SQUID to image the current flow patterns and follow them as a function of gate voltage. We find that the polar LaAlO\textsubscript{3} induces an effective gate bias even when cooling down at zero applied electric field. This effective gate bias has a three-fold effect: it pins the ferroelectric domains near the interface, it reduces the carrier density and confines the current flow. We suggest this effective gate bias as a way to control the initial state of a ferroelectric material. The hysteresis observed both in the normal state and in the superconducting one can lead to a multifaceted controllable memory device.
Nonlinear transport in gate-induced 2D Rashba superconductor SrTiO$_3$

YUKI ITAHASHI (Presenter), TOSHIYA IDEUE, The Univ. of Tokyo, Tokyo, Japan., YU SAITO, University of California at Santa Barbara, Santa Barbara, USA., SUNAO SHIMIZU, Central Research Institute of Electric Power Industry, Yokosuka, Japan., TAKUMI OUCHI, TSUTOMU NOJIMA, Tohoku Univ., Sendai, Japan., YOSHIHIRO IWASA, The Univ. of Tokyo, Tokyo, Japan. — A polar conductor with Rashba spin-orbit coupling is a potential material platform for exotic quantum transport and spintronic functionalities [1,2]. One of their inherent properties is the nonreciprocal transport, where the magnetoresistance becomes inequivalent between the rightward and leftward current directions, because of the breaking of both spatial inversion and time reversal symmetries. Such a rectification effect reflecting polar symmetry has been studied at the interface or bulk polar semiconductor [3,4]. However, the mechanism of the nonreciprocity in a polar superconductor remains elusive.

To elucidate the noncentrosymmetric nature of the Rashba superconductor, we have investigated the nonreciprocal transport in gated SrTiO$_3$, which is known as a 2D Rashba superconductor. We found the gigantic enhancement in the nonlinear resistance in the amplitude and phase fluctuation regions. Also, we discuss the possible origins of nonreciprocity in the 2D Rashba superconductor, such as paraconductivity with a parity mixing in the Cooper pairs and rectified vortex-antivortex motions.

Fingerprints of interface superconductivity in ferroelectric tunnel junctions

FERNANDO GALLEGO (Presenter), 2D Foundry, Instituto de Ciencia de Materiales de Madrid, VICTOR ROUCO, Física de Materiales, Universidad Complutense de Madrid, MARIONA CABERO, Centro Nacional de Microscopía electrónica, Universidad Complutense de Madrid, DAVID SANCHEZ MANZANO, JAVIER TORNOS, Física de Materiales, Universidad Complutense de Madrid, RALPH EL HAGE, KEVIN SEURRE, Unité Mixtée de physique, CNRS, FABIAN ANDRES CUELLAR, ALBERTO RIVERA-CALZADA, ZOUHAIR SEFRIOUI, Física de Materiales, Universidad Complutense de Madrid, FEDERICO MOMPEAN, MAR GARCIA-HERNANDEZ, 2D Foundry, Instituto de Ciencia de Materiales de Madrid, JOSE MARIA GONZALEZ-CALBET, Centro Nacional de Microscopía electrónica, Universidad Complutense de Madrid, JAVIER VILLEGAS, Unité Mixtée de physique, CNRS, CARLOS LEON, JACOBO SANTAMARIA, Física de Materiales, Universidad Complutense de Madrid — Ferroelectric tunnel junctions open the possibility of controlling the tunneling current with the ferroelectric state of the barrier. We have studied ferroelectric tunnel junctions with La$_{0.7}$Sr$_{0.3}$MnO$_3$ (LSMO) bottom electrode, a ferroelectric (FE) BaTiO$_3$ barrier and La$_{0.84}$Sr$_{0.16}$CuO$_3$-$\delta$ (LSCO) top electrode. LSCO is a cuprate capable of hosting large densities of oxygen vacancies (OV), yet superconductivity has never been observed. Coupled switching of oxygen vacancies and the ferroelectric polarization may produce drastic changes of the doping of the interface yielding unexpected electronic phases. We have found that the removal of OV from the cuprate interface has a strong hole doping effect of the material. We have observed the emergence of a new gap in the tunneling differential conductance curves which scales with temperature as a superconducting gap, strongly suggesting the nucleation of a superconducting phase at the interface. Switching the ferroelectric polarization of the barrier with an external electric field enables turning the superconducting gap on and off suggesting the possibility of the field effect control of the interface superconductivity.

In Situ, Monolayer Control over the 2D Electron Gas on SrTiO$_3$*  

XI YAN (Presenter), FRIEDERIKE WROBEL, Materials Science Division, Argonne National Laboratory, Lemont, IL, 60439, USA, HAWOONG HONG, Advanced Photon Source, Argonne National Laboratory, Lemont, IL, 60439, USA, JIRONG SUN, Beijing National Laboratory for Condensed Matter & Institute of Physics, Chinese Academy of Sciences, Beijing 100190, People’s Republic of China, JESSICA L MCCLESNEY, HUA ZHOU, Advanced Photon Source, Argonne National Laboratory, Lemont, IL, 60439, USA, DILLON FONG, Materials Science Division, Argonne National Laboratory, Lemont, IL, 60439, USA — SrTiO$_3$ (001) is the principal material in the field of oxide electronics, due to both its properties and the fact that the composition of its surface can be controlled, leading to TiO$_2$ surface termination. Employing in situ synchrotron X-ray methods during growth by molecular beam epitaxy (MBE) and angle-resolved photoemission spectroscopy (ARPES), we discover the existence of a 2D electron gas (2DEG) at the as-prepared, TiO$_2$-terminated SrTiO$_3$ (001) surface. Interestingly, the 2DEG appears correlated with the presence of a TiO$_2$ double layer [S. Cook et al., Sci. Adv. 5, eaav0764 (2019).], as deposition of single layer of SrO leads to island formation and complete elimination of the 2DEG. The subsequent growth of a TiO$_2$ monolayer leads to smoothing and return of the 2DEG. We will provide an atomic-level description of the evolving surface and how it relates to the surface electronic structure.

*Work supported by the Department of Energy, Office of Science, Basic Energy Sciences under contract no. DE-AC02-06CH11357.
A combined experimental and first principles study of small hole polarons in YTiO$_3$ thin films*

IFLAH LARAIB (Presenter), Materials Science and Engineering, University of Delaware, JIN YUE, Chemical Engineering and Materials Science, University of Minnesota, NICHOLAS F QUACKENBUSH, Materials Measurement Science Division, Materials Measurement Laboratory, National Institute of Standards and Technology, BHARAT JALAN, Chemical Engineering and Materials Science, University of Minnesota, ANDERSON JANOTTI, Materials Science and Engineering, University of Delaware — Rare-earth titanate YTiO$_3$ is a Mott insulator whose electronic structure description has been quite challenging to density functional theory (DFT) calculations within standard (semi)local approximations to the exchange-correlation term. The reported onset of optical absorption in YTiO$_3$ is $\sim$0.6 eV while the calculated Mott-Hubbard gap using hybrid DFT is $\sim$2 eV. Combining experiments on hybrid molecular beam epitaxy (MBE) grown YTiO$_3$ heterostructures with DFT calculations we investigated the electronic and transport properties of YTiO$_3$. We test the performance of the meta-GGA SCAN functional in the description of the electronic structure of YTiO$_3$, comparing the results of hybrid functional and photoemission measurements. We also study the formation, stability and migration of small hole polarons in YTiO$_3$, and compare our findings with the measurements of the Seebeck coefficient and temperature-dependent resistivity. We also carry out a detailed analysis of the effects of the TiO$_6$ octahedral tilt and rotations, and lattice distortions on the Mott-Hubbard gap.

*Theory work was supported by the National Science Foundation Early Career Award Grant No. DMR-1652994. Experimental work supported by the DOE Center for Quantum Materials, University of Minnesota.

Controlling spin-polarized carriers at the SrTiO$_3$/EuO interface via the ferroelectric field effect

WENTE LI (Presenter), ALEXANDER DEMKOV, University of Texas at Austin — Using first principle calculations, we investigate the magneto-electric field effect at the SrTiO$_3$/EuO interface in the BaTiO$_3$/SrTiO$_3$/EuO heterostructure. The spontaneous polarization in tetragonal BaTiO$_3$ is demonstrated to control the movement of the two-dimensional electron gas in SrTiO$_3$ across the interface with ferromagnetic EuO as well as induce spin polarized two-dimensional hole gas and influence the electronic structure at this interface. We also investigate the effect of oxygen vacancy in SrTiO$_3$ near the SrTiO$_3$/EuO interface. To investigate the ferroelectric polarization morphology, we use the phenomenological Landau-Khalatnikov model and compare it with the results of first principle calculations.
10:24AM F64.00011: Anomalous Transverse Resistance at the Interface of (111) (La$_{0.3}$Sr$_{0.7}$)(Al$_{0.65}$Ta$_{0.35}$)O$_3$ /SrTiO$_3$ Heterostructures* PATRICK KRANTZ (Presenter), VENKAT CHANDRASEKHAR, Northwestern University, ZHEN HUANG, KUN HAN, ARIANDO ARIANDO, THIRUMALAI VENKATESAN, Department of Physics, National University of Singapore — A variety of interesting physical phenomenon have been found to live at the interface between complex oxide layers. Significant work has been done to characterize the electrical transport properties of the two dimensional conducting gases present in systems like LaAlO$_3$ (LAO)/ SrTiO$_3$ (STO). Recently, (La$_{0.3}$Sr$_{0.7}$)(Al$_{0.65}$Ta$_{0.35}$)O$_3$ (LSAT) /STO has been investigated due to improved lattice matching when compared to LAO/STO, and interesting effects due to strong spin orbit interactions$^{1,2}$. Here we report an anomalous transverse resistance observed in Hall bars at the interface of (111) oriented LSAT/STO. This effect does not track with low field Hall coefficient, nor longitudinal resistance over temperatures from 4 K to 70 K. We discuss these findings in the context of similar effects seen in La$_{2-x}$Sr$_x$CuO$_4$ (LSCO)/STO and LAO/STO systems$^{3,4}$.

*US DOE Grant No. DE-FG02-06ER46346

10:36AM F64.00012: Synthesis of epitaxial ferrimagnetic NiCo$_2$O$_4$ thin films on SrTiO$_3$ and Sr$_3$Al$_2$O$_6$ buffered SrTiO$_3$ substrates* QIUCHEN WU (Presenter), LE ZHANG, YIFEI HAO, XIA HONG, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska - Lincoln — The inverse spinel NiCo$_2$O$_4$ (NCO) is ferrimagnetic with high Curie temperature ($T_C$) and spin polarization. It is of high research interest to integrate it with other functional oxides, while many of them have the perovskite structure. We investigated the effects of a perovskite substrate on the magnetotransport properties of NCO by depositing 30 nm NCO thin films on SrTiO$_3$ (STO) and Sr$_3$Al$_2$O$_6$ (SAO) buffered STO substrates using off-axis RF magnetron sputtering. Both types of samples exhibit insulating behavior below 300 K, and the films on SAO buffered STO shows more than 10 times higher resistivity at 300 K. We estimated the $T_C$ from the magnetoresistance hysteresis. These samples show $T_C$ of up to 150 K, well below that for films deposited on MgAl$_2$O$_4$ substrates (above 300 K). The reduced $T_C$ can be attributed to a high density of anti-phase boundaries due to the structural mismatch between NCO and STO. We also discuss the possibility of suspending the NCO thin films by water etching the SAO buffer layer.

10:48AM F64.00013: Deal-Grove-like thermal oxidation of Si (001) buried under a thin layer of SrTiO$_3$*

WEI GUO (Presenter), AGHAM POSADAS, ALEXANDER DEMKOV, University of Texas at Austin — Dry oxidation of Si (001) beneath a thin epitaxial SrTiO$_3$ layer has been studied using furnace annealing in flowing oxygen. A 10-nm layer of SrTiO$_3$ is epitaxially grown on Si with no SiO$_2$ interlayer. For such a structure, an annealing temperature of 800°C was found to be the limiting temperature to prevent silicate formation and disruption of the interface structure. The effect of annealing time on thickness of the SiO$_2$ layer was investigated. *In situ* x-ray photoelectron spectroscopy (XPS) and reflection-high-energy electron diffraction (RHEED) were used to ensure that the quality of SrTiO$_3$ is unchanged after the annealing process. The experimental annealing data is compared with a theoretical oxygen diffusion model based on those due to Deal, Grove and Massoud. The model fits the experimental data well, indicating that oxygen diffusion through the SrTiO$_3$ layer is not the limiting factor. One can therefore readily control the thickness of the SiO$_2$ interlayer by simply controlling the annealing time in flowing oxygen.

*This research was partially supported by the National Science Foundation through the Center for Dynamics and Control of Materials: an NSF MRSEC under Cooperative Agreement No. DMR-1720595 and by the Air Force Office of Scientific Research under Grant FA9550-18-1-0053.

8:00AM F65.00001: High-Q Nanophotonic Resonators on Diamond Membranes using Atomic Layer Deposition TiO2*

AMY BUTCHER (Presenter), XINGHAN GUO, ROBERT SHREINER, KAI HAO, ALEXANDER A HIGH, University of Chicago — Nanophotonic resonators are critical elements in solid state quantum networks, as they enable individual optical photons to interact with quantum spin states. In diamond, current techniques to fabricate these devices often introduce significant surface roughness and lattice strain, which limit performance and scalability. Using atomic layer deposition of TiO2, we developed a nanophotonic fabrication platform that avoids substrate etching while retaining the potential for high-cooperativity interfacing with color centers in thin diamond membranes. The resulting devices are exceptionally smooth and can be built on arbitrary substrates. In this work, we fabricated ring resonators and 1D photonic crystal cavities with quality factors exceeding $10^4$ and demonstrated our platform’s potential for quantum networking applications on diamond.

8:12AM F65.00002: Single crystal diamond membranes for quantum networking and sensing*  
XINGHAN GUO (Presenter), Pritzker School of Molecular Engineering, University of Chicago, NAZAR DELEGAN, Center for Molecular Engineering and Materials Science Science Division, Argonne National Laboratory, AMY BUTCHER, DAVID AWSCHALOM, Pritzker School of Molecular Engineering, University of Chicago, JOSEPH P HEREMANS, Center for Molecular Engineering and Materials Science Science Division, Argonne National Laboratory, ALEXANDER A HIGH, Pritzker School of Molecular Engineering, University of Chicago — Atomic defects in single crystal diamond, such as nitrogen vacancy centers and silicon vacancy centers, are promising qubit candidates for quantum communication and quantum sensing applications. However, it is difficult to fully utilize their advantages in bulk diamond due to its high refractive index and limited nanofabrication methods. Therefore, to allow better integration flexibility of color centers while maintaining their coherence properties, we developed a process to create high quality, atomically smooth, large-scale single crystal diamond membranes that can be placed on any carrying wafers. Herein we will present the fabrication steps in detail, including He\(^+\) implantation, CVD overgrowth, electrochemical etching, flipping, transfer, and backside etching. Additionally, recent progress related to the integration of these diamond membranes will be demonstrated, namely, photonic cavity integration and creation of group IV and nitrogen vacancy defect centers, which would be beneficial in multi-qubit network, hybridized quantum systems, and quantum sensing.

*This work is partially supported by DARPA. The Diamond CVD growth at Argonne National Lab is supported by the US Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.

8:24AM F65.00003: Single-shot readout of \(^{171}\text{Yb}:\text{YVO}\) ions embedded in a nanophotonic cavity*  
JONATHAN KINDEM (Presenter), ANDREI RUSKUC, JOHN G BARTHOLOMEW, JAKE ROCHMAN, YAN QI HUAN, ANDREI FARAON, Caltech — Solid-state emitters coupled to photonic resonators are an attractive platform for building quantum light-matter interfaces required for scalable quantum networks. Rare-earth ions (REIs) in solids offer a promising system for such interfaces due to their long optical and spin coherence times at cryogenic temperatures, but harnessing these properties at the single ion level has proven to be challenging due to the inherently weak coupling of REIs with light. Here we present the initialization, coherent manipulation, and readout of individual ytterbium-171 ions embedded in a nanophotonic cavity fabricated directly in the yttrium orthovanadate (YVO) host crystal. These ions possess coupled electron-nuclear spin states that are first-order insensitive to magnetic field fluctuations, which allows for optical linewidths less than 1 MHz and spin coherence times greater than 30 ms. We show that Purcell enhancement in the nanophotonic cavity increases the optical emission rate by a factor of 120 and improves the cyclicity of the cavity-coupled optical transitions, which enables efficient initialization and conditional single-shot readout of the hyperfine spin state with fidelity greater than 95%.

*The authors gratefully acknowledge funding from the NSF, IQIM, and AFOSR.
8:36AM F65.00004: Spin dynamics of 171Yb:YVO ions embedded in a nanophotonic cavity*
ANDREI RUSKUC (Presenter), JONATHAN KINDEM, JOHN G BARTHOLOMEW, JAKE ROCHMAN, YAN QI HUAN, ANDREI FARAON, Caltech — Optically addressable spin qubits in solid state hosts are a promising platform for developing scalable quantum networks. We present results on a possible architecture based on single 171 Yb ions doped into yttrium orthovanadate. By coupling these ions to nanophotonic cavities we leverage the Purcell regime of cavity QED to enhance the weak, highly coherent optical transitions typically associated with rare earth ions thereby enabling detection and readout. This talk focuses on ground state spin dynamics. At zero field, the combination of electron and nuclear spin 1/2 leads to a clock transition that is first-order insensitive to magnetic field fluctuations. Ramsey coherence times are limited by interactions with slowly fluctuating lattice spins via second-order perturbations to the Yb ion Hamiltonian. By applying CPMG dynamical decoupling sequences we can extend the spin coherence time to 30ms at temperatures up to 1.2K. Furthermore, we investigate spin lifetimes (T1) in the ground state manifold and find that these are limited by magnetic dipole-dipole interactions with other Yb ions. We also discuss the prospects of working with this platform at high magnetic field and demonstrating remote spin-spin entanglement.

*The authors acknowledge funding from the NSF, IQIM and AFOSR MURI.

8:48AM F65.00005: An in-situ single photon source detection platform for deterministic nanometer resolution ion implantation*
MICHAEL TITZE (Presenter), KULTURANSINGH HOOGHAN, Sandia National Laboratories, HAN HTOON, Los Alamos National Laboratory, EDWARD S BIELEJEC, Sandia National Laboratories — Single photon sources (SPS) are of interest for usages from metrology to the basis of quantum communication, computation and sensing. SPS based on color centers in SiC and other wide band gap semiconductors such as hBN, diamond, etc. require the control over both the positioning as well as the number of optically active color centers. We have developed focused ion beam implantation using our nanoImplanter (nI) which allows spatial control to <50 nm and implantation down to single impurity atoms using counted ion implantation. However, the typical conversion efficiency from implanted impurity atom to optically active color center can range from <3% to >80% depending on the material and the implantation energy. For these low efficiency processes an in-situ technique to identity the creation of SPS is required. To this end we have designed an in-situ photoluminescence (PL) setup integrated into the nI allowing for detection of single photon emission during ion implantation. Using this PL setup in conjunction with a Hanbury Brown Twiss interferometer allows us to deterministically create and measure single color centers in a range of materials systems with nanometer resolution.

9:00AM F65.00006: Introduction of spin centers in single crystals of \( \text{Ba}_2\text{CaWO}_{6-\delta} \) - MEKHO

Sinha (Presenter), Johns Hopkins University, Tyler J. Pearson, Chemistry, Northwestern University, Allen Scheie, Timothy Reeder, Hector K. Vivanco, Johns Hopkins University, Danna Freedman, Chemistry, Northwestern University, William Adam Phelan, Tyrel McQueen, Johns Hopkins University — Electronic spins are ideal qubit candidates both for their modularity and their ease of manipulation with microwave radiation. While fundamentally, \( T_2 \), the spin-spin relaxation time, represents the functional operating time of a qubit, \( T_1 \), the spin-lattice relaxation time, is ultimately the most restrictive parameter, as \( T_1 \) represents the theoretical upper limit to \( T_2 \). Design approaches to maximize \( T_1 \) remain an open question. We report the coherence properties of \( W^{5+} \) spin centers in \( \text{Ba}_2\text{CaWO}_{6-\delta} \) generated by oxygen vacancies. We characterized these defects by measuring the \( T_1 \) and \( T_2 \) times from \( T = 5 \) to 150 K. Correlation of the \( T_1 \) lifetimes obtained from pulse EPR with phonon modes obtained from the heat capacity data quantifies the contribution of respective phonon modes to the spin-phonon coupling in the system. These results demonstrate that systematic defect generation in double perovskite structures can generate viable paramagnetic point centers for quantum applications.

Alexander Crook (Presenter), Christopher Anderson, Department of Physics, University of Chicago, Kevin Miao, Alexandre Bourassa, Pritzker School of Molecular Engineering, University of Chicago, Hope Lee, Department of Physics, University of Chicago, Sam L Bayliss, Pritzker School of Molecular Engineering, University of Chicago, David O Bracher, Xingyu Zhang, Department of Physics, Harvard University, Hiroshi Abe, Takeshi Oshima, National Institutes for Quantum and Radiological Science and Technology (QST), Evelyn L Hu, Department of Physics, Harvard University, David Awschalom, Pritzker School of Molecular Engineering, University of Chicago — Silicon carbide (SiC) has recently been developed as a platform for optically addressable spin defects in the form of the neutral divacancy, most notably in the 4H polytype [1-3]. Here we present the Purcell enhancement of a single divacancy coupled to a photonic crystal cavity. We use a combination of nanolithographic techniques and a dopant-selective photoelectrochemical etch to produce suspended cavities with quality factors exceeding 5000. This corresponds to a Purcell factor of \( \sim 50 \) for a divacancy within the cavity mode and results in an increased photoluminescence into the zero-phonon line (ZPL) when on resonance with the cavity, as well as a shortened excited state lifetime. Additionally, we observe coherent control of the divacancy ground state spin inside of the cavity nanostructure. This system represents a major advance towards applications for the scalability of long-distance entanglement protocols using SiC that require the interference of indistinguishable photons from spatially separated single qubits.

9:24AM F65.00008: Engineering Light-Hole Quantum States in an Optically Active Group IV Low Dimensional System  ANIS ATTIAOUI (Presenter), SIMONE ASSALI, OUSSAMA MOUTANABBIR, Ecole Polytechnique de Montreal — Hole spins have attracted a great deal of attention because of their reduced coupling to the nuclear spin bath. However, most of experimental investigations on 2D gas systems have so far focused on heavy-hole states (HH). This is attributed to the nature of the heterostructure currently exploited, where compressive strain lifts the valence band degeneracy and leaves HH states energetically well above the light-hole (LH) states. However, the ability to exploit LH states will be a powerful paradigm beneficial for quantum information technologies, as the orbital angular momentum of LH states makes them more powerful and versatile. To harness these largely unexplored advantages of LH states, we present a new low-dimensional system consisting of highly-strained Ge quantum well (QW) grown on silicon wafers using GeSn as barriers. To quantify the effect of the LH confinement as well as the LH-HH mixing, several spectroscopic techniques were used to identify the LH confined states in the Ge well. The obtained heterostructure shows optical transitions that can be modulated in the midinfrared range. This ability to engineer quantum structure where LH is the ground state in an optically active group IV platform lays the groundwork for a new class of Si-compatible quantum technologies.

9:36AM F65.00009: First-principles theory of highly correlated electronic states in semiconductor spin qubits*  HE MA (Presenter), University of Chicago, MARCO GOVONI, Argonne National Lab, GIULIA GALLI, University of Chicago — Point defects in wide-gap semiconductors are promising platforms for quantum sensing applications and quantum networks. We present a quantum embedding theory to describe highly correlated electronic states of point defects that are not addressable by conventional density functional theory. We describe the implementation of the method, built on the coupling of the Qbox (www.qboxcode.org/) and WEST (http://www.west-code.org) codes [1], and we demonstrate its accuracy and efficiency for the nitrogen-vacancy center in diamond and several other defects in diamond and SiC.

*Supported by the Midwest Integrated Center for Computational Materials (MICCoM) as part of the Computational Materials Sciences Program funded by DOE/BES
9:48AM F65.00010: Electrically driven optical interferometry with spins in SiC* KEVIN MIAO (Presenter), ALEXANDRE BOURASSA, CHRISTOPHER ANDERSON, SAMUEL J WHITELEY, ALEXANDER CROOK, SAM L BAYLISS, GARY WOLFOWICZ, Pritzker School of Molecular Engineering, University of Chicago, GERGÖ THIERING, PÉTER UDVARHELYI, VIKTOR IVADY, Wigner Research Centre for Physics, Hungarian Academy of Sciences, HIROSHI ABE, TAKESHI OHSHIMA, National Institutes for Quantum and Radiological Science and Technology, ADAM GALI, Wigner Research Centre for Physics, Hungarian Academy of Sciences, DAVID AWSCHALOM, Pritzker School of Molecular Engineering, University of Chicago — Interfacing solid-state defect electron spins to other quantum systems is an ongoing challenge. The ground-state spin's weak coupling to its environment bestows excellent coherence properties [1], but also limits desired drive fields. The excited-state orbitals of these electrons, however, can exhibit stronger coupling to phononic and electric fields [2]. Here, we demonstrate electrically driven coherent quantum interference in the optical transition of single, basally oriented divacancies (VV) in commercially available 4H silicon carbide [3]. By applying microwave frequency electric fields, we coherently drive the VV's excited-state orbitals and induce Landau-Zener-Stückelberg interference fringes in the resonant optical absorption spectrum. Additionally, we find remarkably coherent optical and spin subsystems enabled by the basal VV's symmetry. These properties establish VVs as strong candidates for quantum communication and hybrid system applications, where simultaneous control over optical and spin degrees of freedom is paramount.

10:00AM F65.00011: Controlling Number of Dopants per Site in Si:P Quantum Devices JONATHAN WYRICK (Presenter), XIQIAO WANG, RANJIT KASHID, PRADEEP NAMBOODIRI, FAN FEI, RICHARD SILVER, National Institute of Standards and Technology — STM-based fabrication of atomically precise Si:P structures has been demonstrated as a promising platform for the realization of dopant-based qubit quantum computing. There is a growing broader interest in applying this technique to other quantum systems in Si, for example artificial lattices to engineer band structure, as well as arrays of atoms acting as tunable Hubbard simulators. We present results from a single-atom transistor and few-atom cluster transistors demonstrating the effect that the number of dopants per site has on the energy spectrum of these devices, with the important implication that for many applications of interest it will be necessary to control this parameter with absolute precision. We detail our efforts using STM-based feedback-controlled techniques to engineer placement and number of dopants per site with the goal of reducing the fabrication uncertainty of dopants per site to zero.
10:12AM F65.00012: Tracking interfacial disorder in SiGe qubit material* LUIS FABIAN PEN (Presenter), JUSTIN C KOEPKE, EZRA BUSSMANN, Sandia National Laboratories — Theory predicts quantum dot electrons interact with interface atomic-scale disorder, perturbing energetics, creating new potentially useful states, and adding complexity that could dictate viability of some future qubit technologies. Although profoundly impactful, the predictions are challenging to test, since relevant structures are difficult to measure and correlate with qubit behavior. We've measured atomic step disorder at Si/SiGe interfaces using scanning tunneling microscopy coupled to an epitaxial growth tool. We report a counterintuitive evolution of roughness and step spatial correlations during growth. The results are meaningful toward elucidating structure-function relationships in SiGe QDs.

10:24AM F65.00013: Device development and characterization of Er doped epitaxial Y2O3 on Silicon platform* MANISH KUMAR SINGH (Presenter), University of Chicago, ABHINAV PRAKASH, GARY WOLFOWICZ, Argonne National Lab, YIZHONG HUANG, CHRISTINA WICKER, University of Chicago, ALAN DIBOS, JIANGUO WEN, TIJANA RAJH, Argonne National Lab, DAVID AWSCHALOM, TIAN ZHONG, SUPRATIK GUHA, University of Chicago — Spin-optical interface in rare-earth ions enables storage of optical quantum information in the long-lived nuclear spin levels. Er3+ has an optical excitation that matches the telecom transmission wavelength, making it technologically attractive. Further, very narrow transition linewidths and high spectral stability in Er3+ has been demonstrated when embedded in a crystalline host making it an ideal candidate for solid state quantum memory. Using molecular beam epitaxy (MBE), we demonstrate the growth and characterization of high quality single crystal thin films of Er:Y2O3 on Si 111 and Si 100. Photoluminescence (PL) and EPR show substitution of Er at Y sites. PL linewidths of 7.9 GHz and 6 GHz for the 1536 nm transition are obtained at 4 K and 7 mK, respectively. We will discuss the role of the microstructure, buffer layers, isotopic purity (Er 167), and Er3+ proximity to the interfaces on the optical linewidths. Finally, we report the optical transition lifetime, optical and spin coherence lifetimes on the devices fabricated on this platform. Q values for microdisk resonators and loss (db/cm) in optical waveguides will also be presented.

*Part of the work was funded by EFRC funds through the Department of Energy
Coherent driving of quantum spins via electrically controlled nonlinear magnetization precessions in quantum-classical spin hybrids* AVINASH RUSTAGI (Presenter), Purdue Univ, SHIVAM KAJALE, Indian Institute of Technology Bombay, PRAMEY UPADHYAYA, Purdue Univ — Coherent drives that are spatially local and at the same time add minimal decoherence when manipulating quantum spins, are of significant interest for quantum technology applications. Spin-spin interactions in quantum impurity spin [like Nitrogen vacancy (NV) center]-nanomagnet hybrids provide a platform where spintronic tools controlling nanomagnet dynamics, can be leveraged to coherently drive the quantum spin. However, decoupling coherent and incoherent dynamics is required for attaining large quality factors. Here, we propose to utilize a novel dynamics regime where electrically controlled nonlinear magnetization precessions of a nanomagnet [Nature materials 11, 39 (2012)] can be used to drive the quantum spin to arbitrary quantum states over the Bloch sphere. We demonstrate that the coherent and incoherent dynamics are decoupled in this regime, thereby showing that such quantum-classical spin hybrids can serve as a coherent drive that is local, electrically-controlled, and decoupled from incoherent dynamics.

*We acknowledge NSF grants DMR-1838513 and ECCS 1810494.
Spin triplet superconductivity was recently discovered at temperatures below 1.6 K in the correlated electron compound UTe$_2$ (1), with remarkably anisotropic and large upper critical field values, exceeding 35 T. Although it shares many characteristics with the ferromagnetic spin-triplet superconductors, UTe$_2$ does not order magnetically; instead, it exhibits properties of a quantum critical ferromagnet. The attendant strong magnetic fluctuations likely play an important role in establishing the superconducting pairing and protecting it against the typical destabilizing effects of high magnetic fields. Accumulating evidence supports the notion of a spin-triplet, nodal order parameter. Moreover, an unprecedented reentrant superconducting phase has been identified in UTe$_2$ at even higher magnetic fields, between 40 T and 65 T (2).

Manipulation of time reversal symmetry breaking superconductivity in Sr$_2$RuO$_4$ by uniaxial strain* [Invited] HANS-HENNING KLAUSS (Presenter), VADIM GRINENKO, SHREENANDA GHOSH, RAJIB SARKAR, FELIX BRÜCKNER, Faculty of Physics, TU Dresden, Germany, JEAN-CHRISTOPHE ORAIN, ARTEM NIKITIN, DEBARCHAN DAS, ZURAB GUGUCHIA, Paul-Scherrer-Institut, Villigen, Switzerland, JOONBUM PARK, Los Alamos National Laboratory, MARK E BARBER, MPI CPfS, Dresden, Germany, NAOKI KIKUGAWA, 5National Institute for Material Science, Japan, JAKE BOBOWSKI, Department of Physics, Kyoto University, Japan, DMITRY SOKOLOV, MPI CPfS, Dresden, Germany, HUBERTUS LUETKENS, Paul-Scherrer-Institut, Villigen, Switzerland, YOSHITERU MAENO, Department of Physics, Kyoto University, Japan, ANDREW MACKENZIE, CLIFFORD W. HICKS, MPI CPfS, Dresden, Germany — Although the normal-state electronic structure of Sr$_2$RuO$_4$ is known with exceptional precision, even after two decades of research, the symmetry of it's certainly unconventional superconducting state is currently under strong debate, e.g. the long time favoured spin-triplet $p_x + ip_y$ state is ruled out by recent NMR experiments [1]. However, in general time-reversal-symmetry breaking (TRSB) superconductivity indicates complex two-component order parameters. Probing Sr$_2$RuO$_4$ under uniaxial offers the possibility to lift the degeneracy between such components [2]. One key prediction for Sr$_2$RuO$_4$, a splitting of the superconducting and TRSB transitions under uniaxial stress has not been observed so far. Here, we report results of muon spin relaxation (μSR) measurements on Sr$_2$RuO$_4$ placed under uniaxial stress. We observed a large stress-induced splitting between the onset temperatures of superconductivity and TRSB. Moreover, at high stress beyond the van Hove singularity [2], the TRSB phase is suppressed and a long-range ordered magnetic spin density wave phase is observed with an approx. 50 times stronger internal field. We will discuss the uniaxial strain dependent electronic phase diagram and its implications for the symmetry of the superconducting order parameter in Sr$_2$RuO$_4$.

**9:12AM F66.00003: Knight Shift and Leading Superconducting Instability From Spin Fluctuations in Sr$_2$RuO$_4$** [Invited]  
ASTRID RØMER (Presenter), Niels Bohr Institute, University of Copenhagen, ILYA EREMIN, Institut für Theoretische Physik III, Ruhr-Universität Bochum, PETER HIRSCHFELD, Department of Physics, University of Florida, BRIAN M ANDERSEN, Niels Bohr Institute, University of Copenhagen — The chiral triplet pairing scenario proposed for Sr$_2$RuO$_4$ has been challenged by recent nuclear magnetic resonance (NMR) studies [A. Pustogow et al., arXiv:1904.00047 and K. Ishida et al., arXiv:1907.12236]. We perform a detailed theoretical study of spin-fluctuation mediated superconductivity guided by the spin-fluctuation spectrum measured from neutron scattering of this compound. Nodal even-parity solutions as well as odd-parity states with spins aligned predominantly out of the RuO$_2$ planes are found, both of which are compatible with the new data. The usual odd-parity state with spins primarily in the plane, the chiral $k_x+ik_y$, is difficult to stabilize and in contradiction to both NMR and neutron experiments. The presence of nodes in the spectral gap appears as a common feature for both even- and odd parity gaps. A surprising near-degeneracy of the nodal s' and d$_{x^2-y^2}$-wave solutions suggests the possibility of a near-nodal time-reversal symmetry broken s' +id$_{x^2-y^2}$-wave pair state. Finally we discuss local signatures of such a state near nonmagnetic disorder, as well as the possibility of induced SDW in vicinity of impurities and under strain.

**9:48AM F66.00004: Interplay of heavy fermion quantum criticality and unconventional superconductivity** [Invited]  
FRANK STEGLICH (Presenter), OLIVER STOCKERT, JULIA ARNDT, HIRALE S. JEEVAN, Max Planck Institute for Chemical Physics of Solids, CORNELIUS KRELLNER, Goethe University Frankfurt, HUIQIU YUAN, MICHAEL SMIDMAN, Center for Correlated Matter, Zhejiang University, ERWIN SCHUBERTH, MARC TIPPMANN, LUCIA STEINKE, Walther Meissner Institute, TU Munich, QIMIAO SI, Rice University, EMILIAN NICA, Arizona State University, RONG YU, Renmin University of China — According to the ‘Quantum Critical Paradigm’, antiferromagnetic (AF) quantum critical points (QCPs) in pristine heavy fermion metals cause emergent unconventional superconductivity (SC). This will be demonstrated for both CeCu$_2$Si$_2$ (CCS) and YbRh$_2$Si$_2$ (YRS) [M. Smidman et al., Phil. Mag. 98, 2930 (2018)]. CCS exhibits a 3D spin-density-wave QCP and was considered a d-wave superconductor until recently, when its specific heat was found to follow an exponential temperature dependence at low temperatures [S. Kittaka et al., Phys. Rev. Lett. 112, 067002 (2014)]. Based on atomic - substitution, neutron - scattering and penetration - depth results we show that CCS cannot be an (isotropic/anisotropic) s-wave superconductor but is best described by a model for a fully gapped two-band d-wave superconductor [G. M. Pang et al., Proc. Natl. Acad. Sci. USA 115, 5343 (2018); E. N. Nica et al., npj Quantum Materials 2, 24 (2017)]. YRS exhibits a magnetic-field induced partial-Mott AF QCP. For this material, no SC had been detected above 10 mK. However, magnetic and specific-heat measurements performed to about 1 mK revealed HF, i.e., unconventional, SC to develop at $T_c = 2$ mK. This is ascribed to a competition between nuclear-dominated AF hybrid order and the primary AF order of the 4f-electron spins by which the system is pushed towards its QCP [E. Schuberth et al., Science 351, 485 (2016)]. Our observations support the relevance of the Quantum Critical Paradigm, regardless of the microscopic origin of the AF instability.
Pairing Tendencies, Orbital Selective Mott Phases, and Magnetic Block States in Multiorbital Models for Iron-Based Ladders and Chains* [Invited] ELBIO DAGOTTO (Presenter), University of Tennessee, Knoxville, and Oak Ridge National Laboratory — The discovery of superconductivity at high pressure in iron-based two-leg ladder 123 materials [1] established a new playground to better understand pairing tendencies in iron superconductors. Similarly as in Cu-oxide ladders, computational calculations using correlated electronic models can be performed with good accuracy in quasi-1D systems. Here, I will review our recent results for multiorbital Hubbard models varying the Hubbard and Hund couplings, and the electronic density. Clear indications of pair formation are found in lightly-doped ladders [2] and chains [3], and robust spin-singlet pair-pair correlations develop in those chains [3] (as in Cu-based ladders, we assume pressure leads to doping of the iron network [4]). An explanation for spin-singlet pairing based on an "orbital resonant valence bond" state is discussed for chains [5]. The magnetic properties in ladders and chains are also unexpectedly rich. An "orbital selective Mott phase" dominates in a wide range of parameters. In this regime, magnetic ``block" states emerge, such as up-up-down-down patterns. We calculated the dynamical spin structure factor, finding a mixture of acoustic and optical modes [6] as in neutron experiments. Even more extended block states were recently discovered [7,8]. This complex behavior unveiled in models for 1D iron superconductors when studied accurately suggests that the physics of these materials could be far richer than anticipated.

Session F67 DCMP: Broken Symmetries and Electron Pairing in Magic-Angle Flat Bands Four Seasons 2-3 - Pablo Jarillo-Herrero, Massachusetts Institute of Technology MIT - Tag(s): Invited
8:00AM F67.00001: Superconductors, Orbital Magnets, and Correlated States in Magic Angle Bilayer Graphene

[Invited] DMITRI EFETOV (Presenter), ICFO-The Institute of Photonic Sciences —

Superconductivity often occurs close to broken-symmetry parent states and is especially common in doped magnetic insulators. When twisted close to a magic relative orientation angle near 1 degree, bilayer graphene has flat moire superlattice minibands that have emerged as a rich and highly tunable source of strong correlation physics, notably the appearance of superconductivity close to interaction-induced insulating states. Here we report on the fabrication of bilayer graphene devices with exceptionally uniform twist angles. We show that the reduction in twist angle disorder reveals insulating states at all integer occupancies of the four-fold spin/valley degenerate flat conduction and valence bands, i.e. at moire band filling factors \( \nu = 0, \pm 1, \pm 2, \pm 3 \), and superconductivity below critical temperatures as high as 3 K close to -2 filling. We also observe three new superconducting domes at much lower temperatures close to the \( \nu = 0 \) and \( \nu = \pm 1 \) insulating states. Interestingly, at \( \nu = \pm 1 \) we find states with non-zero Chern numbers. For \( \nu = -1 \) the insulating state exhibits a sharp hysteretic resistance enhancement when a perpendicular magnetic field above 3.6 tesla is applied, consistent with a field driven phase transition. Our study shows that symmetry-broken states, interaction driven insulators, and superconducting domes are common across the entire moire flat bands, including near charge neutrality.

8:36AM F67.00002: Competing Orders, Nematicity and Novel Josephson Effects in Magic-Angle Graphene Superlattices [Invited] YUAN CAO (Presenter), Massachusetts Institute of Technology MIT — The emergence of two-dimensional materials have provided physicists with unprecedented way of studying the motion of electrons in a superconductor. Although superconductivity itself has been studied for more than a century, the recent advances of “twistronics” research in graphene superlattices brings fundamentally new physics into the picture [1,2]. In this talk I will present that demonstrate some peculiar aspects of magic-angle twisted bilayer graphene (MATBG) which has recently been discovered to exhibit correlated insulating phase and unconventional superconductivity. In an in-plane magnetic field, MATBG exhibits a highly anisotropic critical magnetic field within the sample plane that strongly suggests nematicity in the order parameter of the superconductivity. Furthermore, the phase diagrams of some MATBG samples show a distinctive kink in Tc in the ‘underdoped’ region which is reminiscent of quantum critical point behavior in some cuprates such as YBa$_2$Cu$_3$O$_{6+\delta}$[3]. These observations signify the similarity between MATBG and established strongly-correlated systems, and might provide key insight into the underlying mechanism that is responsible for the emergence of 2D unconventional superconductivity. In a second experiment, we performed transport experiments on versatile gate-defined planar junction devices made from MATBG. Our results show that using this device geometry, all-graphene Josephson junctions can be realized by electrostatic gating with configurable tunneling barrier type and strength. Furthermore, we find peculiar Fraunhofer pattern in a magnetic field that exemplifies the intrinsic low dimensionality of the superconducting phase. These results pioneer in novel superconducting devices based on twisted bilayer graphene and might be utilized in future magnetic field sensing applications.

9:12AM F67.00003: Engineering Correlation and Topology in Two-Dimensional Moire Superlattices [Invited] FENG WANG (Presenter), University of California, Berkeley and MSD, LBNL — Van der Waals heterostructures of atomically thin crystals offer an exciting new platform to design novel electronic and optical properties. In this talk, I will describe how to engineer correlated and topological physics using moire superlattice in two dimensional heterostructures. I will show that we can realize and control extremely rich condensed matter physics, ranging from correlated Mott insulator and superconductivity to ferromagnetism and topological Chern insulator, in a single device featuring the ABC trilayer graphene and boron nitride moire superlattices.
9:48AM F67.00004: Strong coupling phases of partially filled twisted bilayer graphene
narrow bands.* [Invited] OSKAR VAFEK (Presenter), Florida State Univ, JIAN KANG, Soochow University, Suzhou, China — States favored by Coulomb interactions projected onto the basis of the four narrow bands of the “magic angle” twisted bilayer graphene will be presented. Due to the unusual shape and symmetry of the Wannier orbitals [1], the resulting strong coupling problem is qualitatively different from the much studied (topologically) trivial narrow band i.e. a solid in an atomic limit. Instead, a dramatically new form of the interaction Hamiltonian is obtained [2]. It contains terms beyond the usual Hubbard term, leading to different strong coupling phases as in the atomic limit. Specifically, the usual anti-ferromagnetic super-exchange mechanism fails and turns ferromagnetic with an approximate spin-valley SU(4) symmetry.
Results of DMRG and variational trial state calculations will also be presented.

*NSF Grant No. DMR-1916958 and NSF Grant No. DMR-1157490

10:24AM F67.00005: Correlated insulating states and broken symmetries in magic angle
twisted bilayer graphene* [Invited] MING XIE (Presenter), University of Texas at Austin, PAWEL POTASZ, Wroclaw University of Technology, ALLAN MACDONALD, University of Texas at Austin — Magic angle twisted bilayer graphene exhibits insulating and superconducting behaviors when its low energy flat bands are partially filled[1]. Insulating states have been seen near all integer band filling factors, which strongly suggests that they are associated with states that break spin/valley flavor but not translational symmetries. I will first present our understanding of the nature of the insulating states[1] based partially on self-consistent Hartree-Fock (SCHF) calculations, which show that the insulating states can be understood qualitatively in terms of broken symmetries that gap the continuum model’s Dirac points as the twist angle is approached[2] from above and the Dirac velocities approach zero. Remote conduction and valence bands play an important quantitative role. Screening of Coulomb interactions due to the response of the metallic gates weakens Coulomb interactions, and can among other effects enlarge the stability region of superconducting states. Away from integer filling the bilayer system is metallic. I will argue on the basis of recent experiments that spin/valley flavor symmetries are often broken even in metallic and superconducting states and extend our SCHF calculations to metallic cases in an effort to shed light on electronic properties in the metallic regime. I will also discuss our recent effort using exact diagonalization method calculations based on a continuum-model defined low energy Hilbert space, which confirm some of the main results obtained using SCHF and point to some limitations. The exact diagonalization calculations suggest that Coulomb interaction alone are not enough to yield Cooper pairing, and that phonon induced effect attractive interactions have to be included in order to have a Cooper instability.

8:00AM F68.00001: Statistical Mechanics and Phase Transitions of Semiflexible Polymers*

[Invited] KURT BINDER (Presenter), Johannes-Gutenberg Univ — By large scale computer simulations theoretical concepts on semiflexible polymers are tested. When the chain stiffness varies, crossover scaling of the polymer radius occurs in bulk dilute solutions. For contour lengths $L$ exceeding the persistence length $l$, gaussian coils occur only in $d=3$ dimensions: in $d=2$ coil swelling due to excluded volume begins for $L > l$. The initial decay length of orientational correlations in $d=2$ is twice as large as in $d=3$; but adsorbed chains do not behave strictly two-dimensional, perpendicular excursions occur on a lateral scale of the deflection length, and a gradual crossover of the decay length of orientational correlations is found. The adsorption threshold scales with the minus $1/3$ power of $l$. In concentrated lyotropic solutions, nematic order occurs; the transition depends on both ratios $L/l$ and $D/l$ ($D =$ chain thickness). The effect of deflection length fluctuations on nematic order is elucidated, and the transition to smectic order is studied.

*Support by the Deutsche Forschungsgemeinschaft and the Alexander von Humboldt foundation is acknowledged.

8:36AM F68.00002: Cartilage-inspired superlubricious hydrogels*

[Invited] JACOB KLEIN (Presenter), Weizmann Institute of Science — The uniquely-efficient lubrication of articular cartilage up to high physiological pressures in the major joints (hips and knees) has been attributed to surface boundary layers of macromolecules complexed with phosphatidylcholine (PC) lipids, where the exposed highly hydrated phosphocholine groups massively reduce friction via the hydration lubrication mechanism. We have emulated nature by constructing hydrogels exposing similar PC-based boundary layers at their surfaces, and by incorporating such PC lipids in the hydrogel bulk we achieve self-maintaining lubricant layers which permanently reduce the friction and wear of the hydrogels by up to a 100-fold or more, down to the superlubrication level (coefficient of friction < 0.01) at contact stresses up to many MPa. Such hydrogels hold promise in a wide range of biomedical applications.

9:12AM F68.00003: Some Thoughts On Polyelectrolyte Persistence Length [Invited]  PHILIP PINCUS (Presenter), University of California, Santa Barbara — Electrically charged, intrinsically flexible polymers in low ionic strength aqueous solutions are known to be stretched in order to reduce the Coulomb self-energy. As the solution ionic strength increases with added salt, Debye screening weakens the repulsion between distant parts of the chain and the polymer is envisioned as a semi-flexible chain with a persistence length that is governed by the Debye screening length. However for nearly fifty years, the dependence of this electrostatic persistence length on ionic strength has been controversial. This presentation will discuss recent experiments and theoretical thoughts that might contribute to unraveling this dilemma.

9:48AM F68.00004: Conformational properties and phase behavior of polymers in ionic liquids* [Invited]  ARUN YETHIRAJ (Presenter), University of Wisconsin - Madison — Ionic liquids have generated considerable excitement for their varied potential applications and their interesting physical properties. The viability of ionic liquids (ILs) in materials applications is limited by their lack of mechanical integrity, which may be provided by mixing them with a polymeric material. Recent experiments on polymers in ILs have unearthed a wealth of interesting phenomena that raise fundamental questions. This talk focuses on computational studies of PEO in imidazolium ILs. We develop a physically motivated first principles force field for PEO and [BMIM][BF_4]; this force field is in quantitative agreement with experiment with no adjustable parameters. Based on the same quantum calculations we develop a hierarchy of united atom models with decreasing resolution and increasing computational efficiency. Microsecond simulations are required to obtain converged properties of the polymer, which displays a combination of ring-like and extended conformations. The simulations show the existence of a lower critical solution temperature which arises from conformational restrictions on the polymer molecules at low temperatures.

*This work was supported by US Department of Energy, Basic Energy Sciences through grant DE-SC0017877.
In the first part, we compare two prominent types of transitions on bare substrates: One is the adsorption transition of a loop (a chain with two ends bound to an attractive substrate) driven by an attraction parameter $\varepsilon$, and the other is the loop-stretch transition in a chain with one end attached to a repulsive substrate, driven by an external end-force $F$ applied to the free end. Close to the transition points, both the static and the dynamic behavior of chains with different length are very well described by a scaling Ansatz with the scaling parameters $(\varepsilon-\varepsilon_c)N^{\phi}$ (adsorption transition) and $(F-F_c)N^{\nu}$ (loop-stretch transition), respectively, where $\phi$ is the crossover exponent of the adsorption transition, and $\nu$ the Flory exponent. Explicit crossover functions are based on an Ansatz for the analytical form of the order parameter distributions at the respective transition points. The transition between the adsorbed state and the stretched state is first order. Nevertheless, the characteristic relaxation time is found to grow according to a power law as the transition point is approached. We present a dynamic effective interface model which reproduces these observations an provides an excellent quantitative description of the simulation data.

In the second part, we discuss the adsorption transition of a single adsorption-active polymer embedded in a polymer brush. This transition is first order and can serve as a basis for the design of a polymer-based sensor or switch with sharp switching transition and fast response time. We discuss in particular the influence of polydispersity in the brush, and show how it can be used to tune the characteristics of the switch, i.e., the sharpness of the transition and the response time.

8:00AM F70.00001: Enhanced deep water acoustic range estimation based on ocean General Circulation Models*  
PETER WEICHMAN (Presenter), BAE Systems — Improved acoustic range estimation supports ocean climate monitoring, ocean model improvement, and underwater navigation, and is limited by the availability of accurate models of ocean sound speed variability. I will describe efforts to test the limits of currently available GCM data to accurately estimate absolute range based on data collected during the PhilSea10 experiment using 510 km source-receiver separation. The methods compare observed acoustic records with synthetic records computed through the GCM ocean sound speed model. The most reliable ranging methods, emphasizing the most reproducible parts of the data records, are able to achieve 20 m or better accuracy. The principles underlying these methods are transportable and are expected to provide reliable range estimates in a broad range of deep-water settings. Generalization to ocean regions with stronger, less well characterized dynamics, is a major challenge, requiring new sources of data to constrain the models.

*The Philippine Sea experiments were supported by the Ocean Acoustics Program at the Office of Naval Research under APL-UW grants N00014-08-1-0843, N00014-08-1-0797, N00014-13-1-0009, N00014-15-1-2233 and N00014-18-1-2213, and Scripps Institution of Oceanography grant No. N00014-08-1-0840.

8:12AM F70.00002: Physics-based Inverse Design of Elastic Rods with Deep Neural Network  
LONGHUI QIN (Presenter), WEICHENG HUANG, MOHAMMAD KHALID JAWED, University of California, Los Angeles — Rod-like structures, such as DNA, climbing plants, and cables, pervade the nature and our daily life, which usually assume a deformed shape based on the competition between elastic (stretching, bending, twisting) and external (e.g. gravity) forces. We take a combination of physics-based and machine learning-driven approach to tackle the problem of obtaining the undeformed shape, given the deformed configuration under gravity. Conventional methods typically couple a numerical simulation of the elastic rods with optimization subroutines. We focus on rapidly solving the inverse problem in real-time using the Discrete Elastic Rods (DER) algorithm to simulate the forward problem and deep neural networks (DNNs) to store a large number of solutions. However, problems involving very long rods cannot be stored in DNNs due to the requirement of vast training dataset and insufficient precision in complex regression problems. We overcome this issue by decomposing a large rod into a series of smaller parts; the solution involving the smaller parts are stored in DNNs. Using the balance of forces and moments at the joints between two smaller parts, these smaller solutions are combined together to construct the larger solution.
Synthesizing arbitrary lattice models using a single degenerate cavity*
ZHENGWEI ZHOU (Presenter), SU WANG, XIANG-F A ZHOU, GUANG-CAN GUO, University of Science and Technology of China, HAN PU, Department of Physics and Astronomy, Rice University — We propose a general method to simulate arbitrary lattice models by manipulating optical synthetic dimension in a single degenerate main cavity. Such a cavity supports a large number of degenerate optical modes with different angular momenta. Couplings between different optical modes can be readily controlled. These features allow us to simulate lattice models that are not convenient to realize using other systems, particularly models in high dimensions and with complicated hopping amplitudes. As a concrete example, we demonstrate how to construct two topological lattice models: the two-dimensional Haldane model and a four-dimensional time-reversal invariant model. For the latter case, we show how topological properties can be detected from the outputs of the cavity, where the second Chern number can be extracted. In the presence of open boundaries, the chirality of the Weyl edge modes can also be detected using the input-output formalism of the cavity modes.

The effect of mass fluctuations on Dirac materials sensors for dark matter*
BART OLSTHOORN (Presenter), ALEXANDER BALATSKY, NORDITA — Dirac materials with a non-zero mass term can form a small energy gap that is typically orders of magnitude smaller than accessible with semiconductors. This energy range provides the sensitivity to search for light (i.e. sub-MeV) dark matter while still blocking out the background noise. We study the effect of disorder through a discrete and continuous random mass-term, which both lead to tails (e.g. Lifshitz tails) in the density of states. The presence of disorder puts stringent constraints on the sensor material properties.

*Support from VILLUM FONDEN via the Centre of Excellence for Dirac Materials (Grant No. 11744), the European Research Council under the European Unions Seventh Framework ERS-2018-SYG 810451 HERO, and the Knut and Alice Wallenberg Foundation.
Magnetic proximity and nonreciprocal current switching in a monolayer WTe$_2$ helical edge

WENJIN ZHAO (Presenter), ZAIYAO FEI, TIANCHENG SONG, HAN KYOU CHOI, TAUNO A PALOMAKI, BOSONG SUN, PAUL MALINOWSKI, University of Washington, MICHAEL MCGUIRE, Oak Ridge National Lab, JIUN-HAW CHU, XIAODONG XU, DAVID COBDEN, University of Washington — The introduction of magnetic order into topological band structure gives rise to new phenomena such as proximity effect and nonreciprocal magnetoelectric effects. We couple the helical edges states in a 2D topological insulator, monolayer WTe$_2$, to a 2D layered antiferromagnet, CrI$_3$. We find that the edge conductance is sensitive to the magnetization state of the CrI$_3$, and the coupling can be understood in terms of an exchange field from the nearest and next-nearest CrI$_3$ layers that produces a gap in the helical edge state. We also find that the nonlinear edge conductance depends on the magnetization of the nearest CrI$_3$ layer relative to the current direction. At low temperatures this produces an extraordinarily large nonreciprocal current that is switched by changing the antiferromagnetic state of the CrI$_3$.

Far-field thermal radiation at the optical topological transition

SANJAY DEBNATH (Presenter), EVGENII NARIMANOV, Purdue Univ — We develop theoretical description of far-field thermal emission near optical topological transitions (OTTs). OTTs originate from a transformation in the topology of the phase space in the medium which results in drastic changes in the photonic density of states. In this work, we show that the unique evolution of this transition leads to a characteristic signature in the far-zone thermal emission. In particular, we find (APL 115, 151906 (2019)) a strong asymmetric pattern of reduced emission near the transition from type-I hyperbolic to dielectric responses present in both naturally available and composite media. The existence of the asymmetric feature should be experimentally observable and can be used as a tool to detect the OTT between type-I hyperbolic and dielectric electromagnetic responses.

9:12AM F70.00007: A bizarre state of confined He-3* VALERIY DOLMATOV (Presenter), Univ of North Alabama — Atoms under various types of external confinements have been scrutinized by theorists for many years now. Here, we focus on a He-3 atom whose 1s^2 shell is known to undergo a tiny hyperfine spin-splitting: 1s^2 → 1s↑1s↓. We treat the spin-split He-3 within the known spin-polarized Hartree-Fock approximation which we modify by the incorporation of a spin-dependent adjustable parameter to model the hyperfine splitting. We place He-3 inside a spherical potential box of a height U_0, width Δ (U_0 = 5 Ry, Δ = 5 a.u., as a case study), and an adjustable inner radius R_0. The resultant atomic potential becomes a double-well potential with the inner and outer wells being separated by about 5 a.u. We model the pressure on He-3 by narrowing the inner radius R_0. We find that, at R_0 ≤ 0.85 a.u., the 1s↓-electron migrates into an outer well. The 1s↑-electron remains in the inner well as long as R_0 > 0.4 a.u. We, thus, unravel a possibility of creating a bizarre state of He-3 with the much different orbital radii and energies of the 1s↑- and 1s↓ electrons. At R_0's ≤ 0.4 a.u. both electrons reside in the outer well, far away from the nucleus, and He-3 turns into a novel type of a low-n (n = 1) and low-l (l = 0) "Rydberg" atom.

*A travel grant from the CAS Research Committee at UNA is acknowledged.

9:24AM F70.00008: Benchmark calculations of the doublet S-states of the singly charged carbon ion* SERGIY BUBIN (Presenter), ISTVAN HORNЯYAK, Nazarbayev University, LUDWIK ADAMOWICZ, University of Arizona — We report accurate variational calculations of the five lowest doublet S-states of the C^+ ion. The wave functions of the six-particle system (five electrons and nucleus) have been expanded in terms of 16000 all-particle explicitly correlated Gaussians whose nonlinear variational parameters were subject to extensive optimization. The motion of the finite-mass nucleus has been explicitly included in the Hamiltonian, while relativistic corrections to the energy levels have been computed in the framework of the perturbation theory. Lowest-order quantum electrodynamics (QED) corrections have also been estimated. The results obtained for the energy levels have enabled the determination of transition frequencies with sub-wavenumber accuracy.

*This work has been supported by the Ministry of Education and Science of Kazakhstan (grant No. BR05236454), Nazarbayev University (faculty development grant No. 090118FD5345), and the National Science Foundation (grant No. 1856702).
Compact tunable plasma muon accelerator for ultrashort micron-scale muon pair beams

AAKASH SAHAI (Presenter), University of Colorado, Denver, VLADIMIR D SHILTSEV, Accelerator Research, Fermilab, TOSHIKI TAJIMA, Physics, University of California, Irvine — Experimentally accessible schemes of compact plasma muon acceleration are introduced and modeled using a novel technique of controlled post-processing of cascade showers. These schemes use propagating structures in plasma, driven as wakefields of femtosecond-scale high-intensity laser or dense particle beams, to capture muons of a divergent cascade shower of: (a) hadronic type from proton-nucleon or photo-production reactions or, (b) electromagnetic type. Apart from the direct trapping and acceleration of particles of a raw shower in a plasma wakefield, a conditioning stage is proposed to selectively focus only one of the charge states. Not only is the high gradient of plasma acceleration structures well suited for rapid acceleration to extend the lifetime of short-lived muons but their inherent spatiotemporal scales also make possible production of unprecedented ultrashort, micron-scale muon beams. Compact muon acceleration schemes hold the promise to open up new avenues for applications.

Reinforcement Learning and the Cost of Observation

RORY COLES (Presenter), University of Ontario Institute of Technology, COLIN BELLINGER, ISAAC TAMBLYN, National Research Council of Canada — Reinforcement learning has recently been used for practical application in both physics and chemistry laboratories. When conducting experiments in these environments, measurements can often be expensive, either due to the resources used or the time that is taken. Due to this, measurements are typically taken intermittently or when exploring new conditions. If we were to use reinforcement learning to optimise a laboratory experiment, it would ideally act in a similar manner. Therefore, it would need to act without perfect information and balance the cost of observation with the need for new data.

In this work, we show how an agent can build an internal hypothesis of its environment, using experience from past measurements, that it can then act on. The measurements it will obtain come from various sensors that each have an associated cost. The informativeness will vary given the current state, so the agent needs to determine the most valuable information to sample. We also demonstrate how the agent's behaviour changes when certain measurements are limited by cost.

* We acknowledge the support of the Natural Sciences and Engineering Research Council of Canada (NSERC).
A modified reference approach implemented in Python (MRAIP) to obtain CO\textsubscript{2} emissions in any region\textsuperscript{*}  
HYCIENTH ABOH (Presenter), Department of Physics, Nigerian Army University, Biu, Nigeria, GODFREY EJIROGHENE AKPOJOTOR, MERRIOUS OFOMOLA, Department of Physics, Delta State University, Abraka — There is a general consensus that good quality estimates of CO\textsubscript{2} emissions from fuel combustion are essential for the construction of inventories since they have direct link between fuel use and emission which is key to strategizing how to reduce these emissions. In the study here, we develop a modified reference approach implemented in Python (MRAIP) to obtain the CO\textsubscript{2} emissions in any location such as a country, region, state or town once its apparent consumptions can be determined. The simplicity of the MRAIP is that it can be used to estimate the amount of CO\textsubscript{2} that is emitted in n-litres of fuel combustion with limited additional effort and data requirements. Therefore, it can be used to obtain both small and large scale inventories even with QPython in Android smartphones. The MRAIP was demonstrated to obtain both states and national CO\textsubscript{2} emission inventories in Nigeria from 2000 to 2019. Further, we discuss simple ways to include other major CO\textsubscript{2} emitters which varies from one location to another such as coal/peat, natural gas, deforestation, cement, and even the minor petroleum products as well as bunker fuel which are not included in the MRAIP.

\textsuperscript{*}We appreciate the authorities of the Nigeria National Petroleum Corporation for the availability of the data used in this study.

10:00AM F71.00001: Graduate School Fair 2020 — Graduate schools are invited to distribute literature and meet with students about their graduate programs. Each participating school will receive a small table with signage in the undergraduate student lounge. Both powered and unpowered options are available.

**Tuesday, March 3, 2020 11:15 AM - 2:15 PM**

**Session G01 DAMOP DCMP: Topological States in AMO Systems I** 103 - Zhexuan Gong - Tag(s): Focus
Disorder and topology have many deep connections, and can have a rich combined influence on the transport properties of quantum particles. Some of the most useful and intriguing properties of topological systems relate to the robustness of their edge states with respect to weak disorder. Rich phenomena are expected to occur as strong disorder is added to such systems, relating to the global unwinding of the non-local topological order. Surprisingly, it has even been predicted that the addition of disorder can induce topological order in otherwise topologically trivial materials. Despite these deep and rich connections, the difficulty of creating controlled disorder in real materials has prevented the exploration of disorder-driven changes in topology in experiments. Here we describe how a type of synthetic lattice can be engineered for dilute atomic gases at ultracold temperatures, allowing us to mimic the physics of disordered topological materials. We describe two types of topological transitions driven by the addition of disorder to one-dimensional atomic wires. The first is the breakdown of a nontrivial band topology by the addition of strong disorder, relating to a random-singlet topological transition. The second is a counter-intuitive "order by disorder" transition in which nontrivial topology arises due to disorder, relating to the observation of the topological Anderson insulator phase predicted nearly a decade ago. We discuss extensions to this result, including prospects for exploring disordered topological materials in higher dimensions.

Meier - University of Illinois at Urbana; Fangzhao Alex An - University of Illinois at Urbana; Alexandre Dauphin - Barcelona Institute of Science and Technology, Complesso Universitario di Monte Sant'Angelo; Pietro Massignan - Barcelona Institute of Science and Technology, Universitat Politècnica de Catalunya; Taylor L. Hughes - University of Illinois at Urbana.
Recent experiments have placed cold atoms into optical lattices in the presence of synthetic fields. This talk will review studies of Hubbard-Hofstadter models in regimes revealing topological phases of ultracold fermions arising from the interplay of inter-particle interactions and synthetic fields in kagome and square optical lattices. Focusing on one regime in particular, attractive interactions in a square optical lattice, we find that attractive s-wave interactions lead to a higher-order topological superfluid [1]. Higher-order topological superconductors hosting Majorana-Kramers pairs as corner modes have recently been proposed in solids. Here, we show that such Majorana-Kramers pairs can be realized using a conventional s-wave superfluid in an optical lattice but with a soliton. The Majorana-Kramers pairs emerge at the “corners” defined by the intersections of line solitons and the one-dimensional edges of the system. Our scheme sets the stage for observing possible higher-order topological superfluidity with conventional s-wave superfluids of cold atoms.

12:03PM G01.00003: Topological Phase Transitions in Finite-size Systems Across Boundary Conditions*  

Systems driven unitarily across different topological phases seem to exhibit contrary behaviors depending on their boundary conditions [1] and the commensurability of system sizes [2]. In particular, a “no-go” theorem forbidding the change of the Chern number exists for periodic boundary systems. Here we first demonstrate the scaling of dynamical phase transition points in driven periodic boundary systems for different turn-on speeds and incommensurate system sizes, which consist of a Landau-Zener governed regime and an adiabatic following regime. Similar regimes are also identified in the case of open boundary systems, proving that these boundary conditions agree in the thermodynamic limit. Finally, we show that with slow turn-ons the dc Hall response of a driven fermi sea starting from a trivial state does acquire a non-trivial value in a finite-size system, even when the “no-go” theorem applies.

*The computations were done at the Institute for CyberScience at Penn State.
**12:15PM G01.00004: Tenfold way for quadratic Lindbladians**

SIMON LIEU (Presenter), MAX MCGINLEY, NIGEL COOPER, University of Cambridge — We uncover a topological classification applicable to open fermionic systems governed by a general class of Lindblad master equations. These ‘quadratic Lindbladians’ can be captured by a non-Hermitian single-particle matrix which describes internal dynamics as well as system-environment coupling. We show that this matrix must belong to one of ten non-Hermitian Bernard-LeClair symmetry classes which reduce to the Altland-Zirnbauer classes in the closed limit. The Lindblad spectrum admits a topological classification, which we show results in gapless edge excitations with finite lifetimes. Unlike previous studies of purely Hamiltonian or purely dissipative evolution, these topological edge modes are unconnected to the form of the steady state. We provide one-dimensional examples where the addition of dissipators can either preserve or destroy the closed classification of a model, highlighting the sensitivity of topological properties to details of the system-environment coupling.

*This work was supported by the EPSRC and by a Simons Investigator Award.

**12:27PM G01.00005: Lattice gauge theories and string dynamics in Rydberg atom quantum simulators**

FEDERICA MARIA SURACE (Presenter), PAOLO PIETRO MAZZA, GIULIANO GIUDICI, ALESSIO LEROSE, ANDREA GAMBASSI, SISSA, MARCELLO DALMONTE, ICTP — Lattice gauge theories are at the basis of our understanding of fundamental interactions and quantum simulations are one of the most promising paths to go beyond the exponential complexity of this quantum many body problem. We show that Rydberg atom setups represent an ideal platform for the investigation of equilibrium and non-equilibrium properties of lattice gauge theories, by proving their equivalence to abelian (and possibly non abelian) gauge theories on the lattice. Building on this correspondence, we show that the recently observed anomalously slow dynamics corresponds to a string-inversion mechanism, reminiscent of the string-breaking typically observed in gauge theories.

*This work is partly supported by the ERC under grant number758329 (AGEnTh), and has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No 817482.

**12:39PM G01.00006: Exact quantum many-body scar states intrinsic to periodically driven system in the Rydberg-blockaded atom chain**

SHO SUGIURA (Presenter), Harvard University, TOMOTAKA KUWAHARA, RIKEN, KEIJI SAITO, Keio University — In a periodically driven many-body system, any quantum state usually ends up an infinite temperature state. This is called the Floquet energy eigenstate thermalization hypothesis (Floquet ETH). Here we discuss the violation of the Floquet ETH with realistic Hamiltonians. Our periodically driven model is based on the PXP type interaction, which is demonstrated in a recent experiment in the Rydberg atoms chain by Harvard group. By showing explicit expressions of the wave functions, we exactly prove the existence of the many-body scar states, which show non-thermal behavior, while other states obey the Floquet ETH. In addition, we systematically engineer various periodically-driven Hamiltonians having Floquet many-body scar states.
12:51PM G01.00007: Exact quantum many-body scar states in the two-dimensional PXP model and their dynamical signatures  CHENG-JU LIN (Presenter), Perimeter Inst for Theo Phys, VLADIMIR CALVERA, Physics, Stanford University, TIMOTHY HSIEH, Perimeter Inst for Theo Phys — The two-dimensional PXP model is an effective model describing the dynamics of a two-dimensional Rydberg atom array in the nearest-neighbor blockade regime. We discover exponentially many exact quantum many-body scar states in the two-dimensional PXP model. These exact scar states have valence bond solid order, therefore breaking the lattice translation symmetry, despite being at effectively infinite temperature. As a manifestation of these scar states, we propose a quench experiment starting from a charge-density-wave initial state, resulting in strong oscillations in the total Rydberg-excitation number. Another signature is long-lived valence bond solid order of the scar states after a quench into a weakly perturbed model.

1:03PM G01.00008: Fragmented Hilbert Spaces and Slow Dynamics in Quantum Dimer Models*  JOHANNES FELDMEIER (Presenter), FRANK POLLMANN, MICHAEL KNAP, Tech Univ Muenchen — The presence of dynamical constraints can have severe impacts on the non-equilibrium dynamics of closed quantum systems, leading to slow or even non-ergodic behavior at finite energy densities. One mechanism for the occurrence of such features is a fragmentation of the Hilbert space structure in systems of fractons, consisting of particles with reduced mobility [1]. Within this context, we investigate the connectivity of configuration spaces resulting from the hard core constraint in close-packed dimer models. On the square lattice, we uncover the emergence of effectively immobile defects within a staggered background, whose dynamics is impeded up to high orders in perturbation theory. This fracton-like structure of the low energy Hilbert space is shown to give rise to glassy behavior for states at low temperatures [2]. We further discuss extensions to different lattices and dimensions that allow for the explicit construction of large sets of conserved quantities, leading to slow dynamics and localized modes for typical states also at high energies.

*We acknowledge support from the DFG grant No. KN 1254/1-1 and DFG TRR80 (Project F8).
**1:15PM G01.00009: Thermalization and its Breakdown for a Large Nonlinear Spin**

SHANE KELLY (Presenter), Los Alamos National Laboratory, SHAN-WEN TSAI, Physics and Astronomy, University of California Riverside, EDDY M.E. TIMMERMANS, Los Alamos National Laboratory — By developing a semi-classical analysis based on the Eigenstate Thermalization Hypothesis, we determine the long time behavior of a large spin evolving with a nonlinear Hamiltonian. Despite integrable classical dynamics, we find the Eigenstate Thermalization Hypothesis is satisfied in the majority of eigenstates and thermalization is generic. The exception is a novel mechanism for the breakdown of thermalization based on an unstable fixed point in the classical dynamics. Using the semi-classical analysis we derive how the equilibrium values of observables encode properties of the initial state. We conclude with a discussion of relevant experiments and the potential generality of this mechanism for the breakdown of thermalization.

**1:27PM G01.00010: CPT invariant topological phase in non-Hermitian spin-1/2 quantum systems**

TANMOY DAS (Presenter), Indian Institute of Science, ANANYA GHATAK, Institute of Physics, University of Amsterdam — Non-Hermitian system has recently found its place in laboratories, raising the hope to obtain unconventional and uncharted physical properties. Over the last two to three years, we have made several contributions to time-dependent theory for parity (P), time-reversal (T) invariant non-Hermitian Hamiltonians; delineating its conservation laws, CPT gauge invariance, and new term in the Berry phase. I will talk about a realizable spinful non-Hermitian system exhibiting the non-Abelian Berry phase and supersymmetric edge states.

Ananya Ghatak, Tanmoy Das. arXiv:1907.07333
1:39PM G01.00011: Topological insulator-superconductor phase transition in a non-Hermitian spin chain  
YUNMEI LI (Presenter), XIWANG LUO, JUNPENG HOU, CHUANWEI ZHANG, University of Texas at Dallas — Non-Hermitian systems can host nontrivial topological phases with the topological characterization distinct from Hermitian systems. Here we consider a 1D XY spin model with non-Hermitian out-of-plane magnetic field, which is periodically modulated. For isotropic XY interaction, the system corresponds to a topological insulator (TI) with pseudo-anti-Hermiticity, which supports edge states characterized by the quantized Zak phase. The anisotropy of XY interaction gives rise to superconducting pairing, and the system experiences a transition from TI to topological superconducting (TSC) as the anisotropy increases. The transition point, where the system undergoes a band touch at E=0, can be tuned by the modulation phases and amplitudes of the non-Hermitian field. The TSC phase supports Majorana edge modes, protected by the chiral symmetry. The model can be experimentally simulated with trapped ions. Our work provides a method to investigate the interplay between non-Hermiticity and superconducting interaction and paves the way for exploring various topological insulators and superconductors in non-Hermitian systems.

1:51PM G01.00012: Non-adiabatic topological energy pumps with three incommensurate frequencies  
RONGCHUN GE (Presenter), University of Texas at Dallas, FREDERIK NATHAN, Niels Bohr Institute, TAKAHIRO MORIMOTO, University of Tokyo, SNIR GAZIT, The Hebrew university of Jerusalem, MARK RUDNER, Niels Bohr Institute, MICHAEL KOLODRUBETZ, University of Texas at Dallas — Recent developments have shown topological energy pumping in quantum systems driven with either one or two incommensurate frequencies near their adiabatic limit. In this talk, we generalize such multichromatic Floquet techniques to study the topological properties of one-dimensional systems driven by two non-adiabatic drives and two-level systems driven by three incommensurate drives. We find a well-quantized, topologically non-trivial plateau, given by the topology of the micromotion. As the ratios among the frequencies is increased, the photonic modes become delocalized before a topological transition is reached. At fixed ratio of the frequencies, changing the magnitude of the frequencies gives transitions from topologically trivial to non-trivial and back to trivial again in the large frequency limit. We will also discuss plausible experimental possibilities to observe these novel topological effects.
2:03PM G01.00013: Quadrupole Topological Photonic Crystals* LI HE (Presenter), ZACHARIAH M ADDISON, EUGENE JOHN MELE, BO ZHEN, University of Pennsylvania — Quadrupole topological phases, exhibiting protected boundary states that are themselves topological insulators of lower dimensions, have recently been of great interest. Extensions of these ideas from current tight binding models to continuum theories for realistic materials require the identification of quantized invariants describing the bulk quadrupole order. Here we identify the analog of quadrupole order in Maxwell’s equations for a photonic crystal (PhC). Unlike prior studies relying on threaded flux, our quadrupole moment is quantized purely by crystalline symmetries. Furthermore, through the bulk-edge correspondence of Wannier bands, we reveal the boundary manifestations of nontrivial quadrupole phases as quantized polarizations at edges and bound states at corners. Finally, we relate the nontrivial corner states to the emergent phenomena of quantized fractional corner charges and a filling anomaly.

Session G02 DAMOP: Hybrid AMO/condensed matter quantum systems 105

11:15AM G02.00001: Controlling the motion of levitated particles by coherent scattering ONDREJ CERNOTIK (Presenter), RADIM FILIP, Palacky Univ — Levitated particles are a promising platform for cavity optomechanics owing to lack of clamping losses allowing, in principle, generation of nonclassical mechanical states and high-precision sensing of external forces. One important tool for controlling the particle motion, which has remained largely unexplored, is the trapping field itself. Recently, a crucial step in understanding its capabilities has been made by using coherent scattering of tweezer photons into a cavity mode to cool the motion of a levitated particle. Here, we build on these results and show that coherent scattering, accompanied by amplitude modulation of the trapping beam, can be used for more general control of particle motion. We show how this mechanism (leading to modulation of the mechanical potential, which is impossible with clamped mechanical resonators) can be used to generate strong mechanical one- and two-mode squeezing both in the transient and steady-state regimes. We also discuss how to use these techniques for efficient readout of the mechanical motion similar, in spirit, to two-tone, backaction-evading readout. With straightforward extensions of our ideas to all three motional modes of levitated particles, our results pave the way to full quantum control of particle motion.
11:27AM G02.00002: Dynamical multistability in a quantum-dot laser* MATTIA MANTOVANI (Presenter), Universität Konstanz, ANDREW D. ARMOUR, University of Nottingham, WOLFGANG BELZIG, GIANLUCA RASTELLI, Universität Konstanz — Quantum dots coupled to microwave cavities or nanomechanical resonators allow to investigate novel regimes of electron-phonon and electron-photon interactions, because of their highly tailorable properties. Here, we consider a hybrid implementation of a single-atom laser [1], where a quantum dot with two spin-split levels is coupled to a harmonic resonator and is embedded between two ferromagnetic contacts with opposite polarization. A spin-polarized current driven through the dot brings the resonator in a highly-excited lasing state. We show that the high efficiency of this pumping mechanism breaks the rotating-wave approximation (RWA) usually employed for the laser, without any need of ultrastrong spin-resonator coupling. Remarkably, the oscillator displays a rich multistable regime characterized by a multi-peaked Fock distribution. Multistability can be detected by monitoring the current in time, as it switches between distinct current levels corresponding to different states of oscillation [2].

11:39AM G02.00003: Quantum state preparation for coupled period tripling oscillators* NIELS LOERCH (Presenter), University of Basel, YAXING ZHANG, Yale University, CHRISTOPH BRUDER, University of Basel, MARK DYKMAN, Michigan State University — We investigate the quantum transition to a correlated state of coupled oscillators in the regime where they display period tripling in response to a drive at triple the eigenfrequency. Correlations are formed between the discrete oscillation phases of individual oscillators. The evolution toward the ordered state is accompanied by the transient breaking of the symmetry between seemingly equivalent configurations. We attribute this to the nontrivial geometric phase that characterizes period tripling. We also show that the Wigner distribution of a single damped quantum oscillator can display a minimum at the classically stable zero-amplitude state.

11:51AM G02.00004: Steering sound with light*  
TIRTH SHAH (Presenter), Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, HENGJING REN, Applied Physics and Material Science, Caltech, CHRISTIAN BRENDEL, Max Planck Institute for the Science of Light, HANNES PFEIFER, Institute For Applied Physics, University of Bonn, VITTORIO PIANO, Max Planck Institute for the Science of Light, OSKAR PAINTER, Applied Physics and Material Science, Caltech, FLORIAN MARQUARDT, Max Planck Institute for the Science of Light — Phononic circuits have been emerging as a growing field of research for applications in optical signal processing, sensing and emerging quantum technologies. We describe the design of a micron-scale on-chip patterned silicon device supporting i) helical transport of phonons along the interface of two topologically distinct domains, ii) photonic crystal optical cavities as a means of excitation and read-out of these mechanical vibrations via optomechanical parametric coupling. Our unique design can be characterized as a multi-scale optomechanical crystal, and we will describe possibilities to test its operation in experimental devices.

12:03PM G02.00005: Efficient photon excitation readout for individual erbium ions in silicon  
GUANGCHONG HU (Presenter), GABRIELE DE BOO, CHUNMING YIN, CQC2T, School of Physics, UNSW, MATTHEW J. SELLARS, CQC2T, RSPE, Australian National University, SVEN ROGGE, CQC2T, School of Physics, UNSW — Here we would report the charge detection mechanism of a single erbium ion in a silicon transistor by pulsed light. Erbium atoms were implanted in a silicon transistor and then the device was cooled down to 4K[1]. In the continuous wavelength scan, we saw a binary signal when the erbium ion was on resonance. Based on this feature, instead of using continuous wavelength scan, we utilised Dark-OnRes-Dark-Reset pulse sequences to excite the erbium ion. We found a 30MHz wide line width while the line width was 120MHz via continuous wavelength scan. We would also give a upper bound for the optical lifetime of 13/2 excited state, which is around 20us, limited by the bandwidth of our setup.

12:15PM G02.00006: Study of Erbium-doped yttrium orthovanadate crystal for the microwave to optical transduction* TIAN XIE (Presenter), JAKE ROCHMAN, JOHN G BARTHOLOMEW, ANDREI RUSKUC, JONATHAN KINDEM, IOANA CRAICIU, ANDREI FARAON, Caltech — Quantum transduction between the microwave and optical domain is essential for connecting superconducting quantum platforms in a quantum network. Ensembles of rare-earth ions (REIs) coupled to both optical and microwave cavities offer a promising architecture for achieving this conversion because of their collective and coherent properties in the microwave and optical domains. The critical properties of the REI ensemble needed for high transduction efficiency are the optical and microwave transition dipole moments and the optical and spin inhomogeneities. Erbium ions are of particular interest because they have transitions at telecom wavelengths which allows for the compatibility with optical fiber telecommunication networks. Here, we report the bulk properties of Erbium-doped yttrium orthovanadate (Er:YVO) including the Zeeman splitting, optical absorption spectra, oscillator strength, and spin inhomogeneity. We also demonstrate proof of concept microwave to optical conversion with a loop gap microwave resonator. The measured strong dipole moment and narrow inhomogeneities point to the Er:YVO as a promising material for quantum transduction.

12:27PM G02.00007: INAS QUANTUM DOTS AND SURFACE ACOUSTIC WAVE CAVITIES FOR QUANTUM TRANSDUCTION TRAVIS AUTRY (Presenter), SAMUEL BERWEGER, National Institute of Standards and Technology Boulder, LUCAS R SLETTEN, JILA, University of Colorado, RICHARD MIRIN, PAVEL KABOS, National Institute of Standards and Technology Boulder, KONRAD LEHNERT, JILA, University of Colorado, KEVIN SILVERMAN, National Institute of Standards and Technology Boulder — Quantum information technology based on superconducting microwave technology is progressing rapidly and is now widely adopted by large corporations and small startup firms. These components operate at ~20mK temperatures. An emerging problem is the transfer of quantum information out of and into the cryostat. Recently, hybrid quantum devices involving SAW cavities and superconducting qubits have been successfully integrated [1]. We present progress on a new type of transducer involving an InAs quantum dot and coupled to surface acoustic wave cavity (SAWc). In a SAWc, phonons will parametrically modify the resonance frequency of a QD via strain [2]. In this work, we demonstrate progress in developing state-of-the-art, stable SAWc operating at ~ 3.4GHz. We demonstrate a reduction in the SAWc mode volume by using focusing SAW mirrors. These devices are characterized using near-field microwave measurements of SAWc cavity-modes demonstrating high-quality focusing phononic wavefronts. Finally, we discuss reducing bulk scattering, theoretical coupling rates and discuss efficient photon extraction.

Tunable Microwave Resonators Composed of Stoichiometric Titanium Nitride and Multilayer Titanium Nitride/Titanium

**DAVID S WISBEY, JACOB BREWSTER** (Presenter), Saint Louis University, **MICHAEL R. VISSERS, JIANSONG GAO**, National Institute of Standards and Technology Boulder — Low-temperature high-Q frequency tunable microwave resonators were fabricated and measured. Two different types of material were fabricated and tested: Titanium nitride/titanium (TiN/Ti) multilayers and stoichiometric titanium nitride (sTiN). The multilayer resonators had a tunable resonant frequency and still maintained a high internal quality factor at temperatures around 50 mK. Multilayer TiN/Ti resonators had a $T_c$ of 1.5K and sTiN resonators had a $T_c$ of 4.5K. Biasing was accomplished using lithographically etched lines and an external power supply. The frequency tunability, as before [1], was achieved by injecting a DC through a current-directing circuit into the nonlinear inductor whose kinetic inductance is current dependent. We were able to achieve a frequency tunability of up to 20MHz, or .5 % fractional frequency shift, while maintaining a base temperature of less than 50 mK, without measurable heating of the device. Different lengths and widths of bias lines were compared to determine the effect on the microwave resonators. We were able to achieve an internal quality factor of $Q_i > 250,000$ for certain designs.

Potential applications of solid-state laser cooling in silica glass

**ESMAEIL MOBINI** (Presenter), **MOSTAFA PEYSOKHAN, ARASH MAFI**, University of New Mexico — Solid-state laser cooling (SSLC) can remove heat from materials via anti-Stokes fluorescence cooling. Since the first observation of SSLC in ZBLAN glass in 1995 by R. Epstein et al., a variety of materials have been successfully cooled. Among the materials, Yb-doped crystals have gained more attention than others due to their higher ion solubility that could lead to high cooling efficiency. However, over the past two decades, the laser cooling of silica glass as the most widely used optical material has been void of success. This lack of success has led many to question the possibility of SSLC in silica. Recently, we have observed the SSLC in Yb-doped silica glass that potentially opens up new applications from radiation-balancing in fiber amplifiers to spot-cooling in silicon photonics. Here, we first investigate all the parameters that govern the SSLC in the materials and will show that SSLC in pure silica glass is achievable, and second, revisit some of our results on the SSLC of Yb-doped silica. Finally, we investigate the minimum temperature that an ultra-pure Yb-doped silica glass can achieve.

1:03PM G02.00010: Strain activated hBN color centers in photonic and plasmonic systems*

NICHOLAS PROSCIA (Presenter), ROBERT COLLISON, CARLOS MERILES, VINOD M MENON, The City College of New York — A photonic-chip-based source of quantum light is highly desirable for long range quantum commutation. One promising material system for this is the Van der Waals material hexagonal Boron Nitride (hBN) which hosts room temperature single photon emitters in its bulk and 2d limit. The ultra-thin nature of hBN allows for the ability to conform and integrate with other material systems and offers a way to control its the electronic and optical properties through strain and electro-magnetic nearfields. Here we demonstrate a deterministic coupling method by activation of such emitters via strain applied by mechanical bending at precise locations. We use the topography of the photonic element structure to induce the bending and strain engineer heightened defect emission within the field mode of two micro and nano-photonic elements, e.g. Si$_3$N$_4$ microdisk (MD) cavities and surface lattice resonances (SLRs) of plasmonic Ag pillar array. We subsequently show coupling of the hBN defect emission to these cavity structure and find this method to be a promising step towards more accessible quantum states of light for study in on-chip devices.

1:15PM G02.00011: Absolute quantum efficiency measurement of single photon emitters in hexagonal Boron Nitride

NIKO NIKOLAY (Presenter), Department of Physics, Humboldt University of Berlin, NOAH MENDELSOHN, School of Mathematical and Physical Sciences, University of Technology Sydney, ERSAN ÖZELCI, BERND SONTHEIMER, FLORIAN BÖHM, GÜNTER KEWES, Department of Physics, Humboldt University of Berlin, MILOS TOTH, IGOR AHARONOVICH, School of Mathematical and Physical Sciences, University of Technology Sydney, OLIVER BENSON, Department of Physics, Humboldt University of Berlin — Single photon emitters in two-dimensional hexagonal boron nitride (hBN) have been intensively studied for several years, since their outstanding properties could qualify this material system as promising candidates for future sources of quantum states of light [1]. However, the atomic origin and some important basic properties of these defects are yet unknown. One of them is the quantum efficiency (QE) with respect to the ratio of radiative and non-radiative rate. We have performed an absolute measurement using the Drexhage method, which is free of incomplete excitation saturation, indirect excitation paths and the detection efficiency of the setup. Instead, it relies on lifetime measurements alongside a controlled change in local density of states achieved by a precise mirror placement using an atomic force microscope. In this contribution, we will report on the mentioned method, the experimental results on two emitter families with different QEs (with the highest QE found approaching 87(7) %) [2], the discovery of part of the underlying level system, specifically the absolute de-excitation rates, and the effects on the expected maximum photon count rate.

1:27PM G02.00012: Quantum Correlations in the Stokes-anti-Stokes Raman Scattering: Photonic Cooper Pairs*  
FILOMENO AGUIAR JÚNIOR (Presenter), Physics, Federal University of Minas Gerais (MG) - Brazil - UFMG, ANDRE L SARAIVA, MARCELO FRANÇA SANTOS, BELITA KOILLER, Physics, Federal University of Rio de Janeiro (RJ) - Brazil - UFRJ, REINALDO DE MELO E SOUZA, Physics, Federal University Fluminense (RJ) - Brazil - UFF, ARTHUR PATROCÍNIO PEN, Physics, Federal University of Minas Gerais (MG) - Brazil - UFMG, RAINA ARMOND DA SILVA, Physics, Federal University of Uberlândia (MG) - Brazil - UFU, CARLOS HENRIQUE MONKEN, ADO JORIO, Physics, Federal University of Minas Gerais (MG) - Brazil - UFMG — The production of correlated Stokes (S) and anti-Stokes (aS) photons (SaS process) mediated by real phonon is well known in the literature. However, in recent work we demonstrated that Photons can interact with each other in condensed matter through the same mechanism that forms Cooper pairs in superconductors—the exchange of virtual phonons [Phys. Rev. Lett. 119, 193603 (2017)]. We investigate the energy, momentum and production rate of correlated Stokes–anti-Stokes (SaS) photons in diamond and we show the rate of correlated SaS production depends on the energy shifts of the pair, which in the BCS theory determines whether there should be an attractive or repulsive interaction. With this view, we only observe correlated SaS in the case of attractive interactions [PRB 99, 100503 (2019)]. We also observe that the SaS photons crosses the sample following the same path as the noninteracting laser. Finally, we investigate the polarization of correlated SaS photons, demonstrating that they have mainly the same polarization of the excitation laser. By pump-probe experiments we measure the decay rate of the SaS pair production, evidencing the fundamental difference between the real and virtual phonon exchange processes.

1:39PM G02.00013: Controlling van der Waals Phenomena at the interface of Atomic and Two-Dimensional Dirac Quantum Matter*  
AADITYA DIMRI (Presenter), JOSEPH TURNER, ADRIAN DEL MAESTRO, VALERI KOTOV, Univ of Vermont — We discuss how the presence of two-dimensional (2D) materials, such as graphene, can significantly affect two intrinsically quantum phenomena that have traditionally served as probes of the fundamental van der Waals (VDW) interaction. First, we show theoretically that Quantum Reflection (QR) of slow atoms off attractive VDW potential tails (due to interactions with 2D materials) is very strongly dependent on material characteristics (such as band structure, doping and screening level, etc). Secondly, we analyze manifestations of such 2D effects for many atoms forming a confined Bose-Einstein condensate (BEC) placed near 2D materials, which in turn makes the BEC frequency sensitive to the interface. In both cases we find that relatively small 2D material changes (either by external factors such as strain or doping, or by using gapped 2D materials instead of graphene) can have a profound effect on the above phenomena. In particular, Quantum Reflection at a given energy can experience a significant enhancement or supression (relative to conventionally used bulk materials) making 2D quantum materials an attractive playground for the study of many-body phenomena at the interface of atomic and solid state physics.

1:51PM G02.00014: Magneto-electric Rectification: A New Universal Second-order Nonlinearity*  
MINH T TRINH (Presenter), GREGORY SMAIL, DASEUL YANG, JINSANG KIM, STEPHEN COLBY RAND, Univ of Michigan - Ann Arbor — Ultrafast magneto-electric (M-E) interactions have attracted a great deal of attention because they potentially enable novel ultrafast all-optical switching, sensing technology, and terahertz emission. Most M-E effects have been observed in multiferroic materials or in metamaterials. Very interestingly, it has been reported recently that magnetic properties of homogeneous dielectric media can be controlled by optical nonlinearities driven jointly by electric and magnetic field components of light. Through the action of optical torque at the atomic scale, magneto-electric (M-E) interactions drive the bound electrons to move in curved trajectories even under non-relativistic conditions, breaking temporal and spatial inversion symmetry. As a result, several unforeseen physical phenomena take place, such as longitudinally polarized second harmonic radiation, induced transverse magnetization at the optical frequency, and forward optical rectification. Interestingly, no special crystal symmetry is necessary for M-E rectification. In this work, we report the first observation of the transient forward magneto-electric rectification in a pentacene thin-film using an electric-field-induced second harmonic generation (EFISH) technique.

2:03PM G02.00015: Theory of Magneto-electric Dynamics in Charge Separation*  
GREGORY SMAIL (Presenter), MINH T TRINH, STEPHEN COLBY RAND, Center for Dynamic Magneto-Optics, Univ of Michigan - Ann Arbor — A time dependent theory of magneto-electric nonlinearities at the molecular level is presented, with an emphasis on rectification. Magneto-electric nonlinearities are interactions that involve both the electric and magnetic fields of light. Recent experimental evidence indicates that these interactions are mediated by the transfer of orbital angular momentum to molecular rotations through the action of optical torque at low intensities. By including torque dynamics in an otherwise classical electron oscillator model, a quantitative model of the interactions can be developed to include temporal evolution. The solutions to the equations of motion clearly show the role of both a parametric resonance and torque dynamics in driving the magneto-electric nonlinearities. Simulations are directly compared to experimental measurements of magneto-electric rectification to examine the accuracy of the model.

Session G03 GSCCM DMP: Materials in Extremes: Carbon and Related Materials at Extreme Conditions  
107 - Nir Goldman, Lawrence Livermore Natl Lab
11:15AM G03.00001: Detonation-induced transformation of graphite to hexagonal diamond.* ELISSAIOS STAVROU (Presenter), MICHAEL BAGGE-HANSEN, JOSHUA A HAMMONS, WILLIAM L SHAW, WILL BASSETT, SORIN BASTEA, LISA LAUDERBACH, RALPH HODGIN, NICHOLAS PEREZ-MARTY, MATT NELMS, MATTHEW P KROONBLAWD, BRAD STEELE, SARANSH SINGH, Lawrence Livermore Natl Lab, NICHOLAS SINCLAIR, YUELIN LI, PINAKI DAS, ADAM SCHUMAN, Dynamic Compression Sector (DCS), Washington State University, KAMEL FEZZAA, ALEX DERIY, Advanced Photon Source, Argonne National Laboratory, THOMAS BUNT, LARA LEININGER, TREvor M WILLEY, Lawrence Livermore Natl Lab — The structural evolution of graphite under elevated thermodynamic conditions has been the subject of intense research interest. Early studies, back in 90s, clearly indicate the shock-induced transformation of graphite to a phase with much higher density, presumably a sp$^3$ allotrope, above 20 GPa. However, only recently the capability of in-situ X-ray diffraction under shock conditions allowed the structural characterization of the relevant phases. Here we explore the structural evolution of highly oriented pyrolytic graphite (HOPG) under detonation-induced shock conditions using in situ synchrotron X-ray diffraction in the ns time scale. We observe the formation of hexagonal diamond (lonsdaleite) at pressures above 50 GPa, in qualitative agreement with recent gas gun experiments. Moreover, we observe an extended pressure stability of the initial HOPG crystal structure up to ~50 GPa, in contrast with previous shock and static compression results.

*This work was performed under the auspices of the U. S. Department of Energy by Lawrence Livermore National Security, LLC under Contract DE-AC52-07NA27344. We gratefully acknowledge the LLNL LDRD program for funding support of this project under 18-SI-004.

11:27AM G03.00002: Kinetics of carbon clustering in detonation of high explosives: Particle growth along hydrodynamic streamlines KIRILL VELIZHANIN (Presenter), Los Alamos Natl Lab — Chemical reactions in detonation of carbon-rich high explosives yield solid carbon as a major constituent of the products. Efforts to theoretically describe the kinetics of carbon clustering go back to the seminal paper by Shaw and Johnson, where it was modeled as a diffusion-limited irreversible coagulation of smaller clusters into larger ones. In this talk, we will discuss recent direct experimental observations of carbon cluster growth in detonation of high explosives, based on time-resolved small-angle X-ray scattering (TR-SAXS). We will focus on comparison of these results with calculations based on (i) realistic hydrodynamic modeling of detonation of PBX 9502 high explosive, (ii) the Shaw-Johnson model of carbon particulate growth along the streamline obtained from the hydrodynamic simulations, and (iii) accurate simulations of the TR-SAXS signal. We demonstrate that this three-step simulation approach agrees well with the recent experimental results. The implications of this agreement on our present understanding of in-detonation carbon clustering processes will be discussed.
11:39AM G03.00003: Morphological evaluation of nanophase carbons recovered from deflagrated vs. detonated PBX 9502  MILLICENT FIRESTONE (Presenter), SOKHNA DIOUF, SUZANNE M.L. SHEEHE, Los Alamos Natl Laboratory — Understanding the correlation between detonation conditions and nanophase carbon formation is important for achieving greater accuracy in predicting high explosive performance. To advance our understanding, and ultimately improve our ability to accurately predict the nanophase carbon products, requires knowledge of the operable carbon framework reactions and nascent particle assembly mechanisms ensuing behind the shock front. The detonation chemical reaction zone (CRZ) is temporally short (ns) and spatially small (100’s microns), making it difficult to directly probe. Further complicating direct interrogation is the high optical opacity. Deflagration, however, is less extreme characterized by a larger dimensional reaction zone (mm) that is temporally longer (ms). Furthermore, deflagration produces lower opacity at pressures in the MPa range. Thus, deflagration offers a means for carrying out direct spectroscopic monitoring of the generated and evolving carbon products as a function of HE chemical composition. In this presentation, the morphology of nanophase carbons recovered from the detonation and deflagration soot derived from PBX 9502 is characterized. The data is interpreted in the context of emission spectra recorded in the deflagrating flame.

11:51AM G03.00004: Probing metastability of carbon at high pressures by predictive first-principles simulations  ASHLEY WILLIAMS (Presenter), KIEN NGUYEN-CONG, JONATHAN T WILLMAN, IVAN OLEYNIK, University of South Florida — In spite of extensive experimental and theoretical efforts, the behavior of carbon at extreme conditions is not completely understood. Previous hydrostatic studies demonstrate the stability of diamond and the absence of any other phase of carbon at pressures up to 1 TPa. However, new metastable phases might appear upon uniaxial compression generated by shock waves. We explore unknown metastable phases of carbon under both hydrostatic and uniaxial compressions up to 5 TPa using first-principles crystal structure prediction methods. It is predicted that several new metastable phases appear to survive upon decompression to ambient conditions. The experimental validation of these predictions will open up a new avenue in synthesizing new metastable carbon materials.
12:03PM G03.00005: Bottom up molecular doping approach to synthesizing HPHT color centers in nanostructured diamond*  
ABBIE GANAS (Presenter), MATTHEW J CRANE, RYAN BECK, University of Washington, ALESSIO PETRONE, Dipartimento di Scienze Chimiche, Università di Napoli Federico II, YUE HUANG, University of Washington, RHONDA MICHELE STROUD, United States Naval Research Laboratory, XIAOSONG LI, PETER J. PAUZAUSKIE, University of Washington — Diamond nanocrystals are advantageous for a myriad of biological and technological applications because its optical color centers are tunable between the ultraviolet and near-infrared (NIR) spectral regions. Our work describes a molecular approach to dope diamond nanocrystals with silicon heteroatoms at extreme temperature (>1800K) and pressure (>15 GPa) conditions using argon as a near-hydrostatic pressure medium. Tetraethylorthosilicate (TEOS) molecules chemically dope an amorphous carbon aerogel during nanodiamond synthesis within a laser-heated diamond anvil cell. Pressure-dependent photoluminescence is used in tandem with ab initio quantum cluster calculations to measure the pressure dependence of the SiV- centers’ zero phonon line (λ ~ 738 nm, 0.9 meV / GPa). Aberration-corrected scanning transmission electron microscopy images heteroatoms on the surfaces and also the interiors of diamond nanocrystals. Scanning transmission x-ray absorption microscopy (STXM) measurements, along with electron energy loss spectroscopy and ab initio quantum cluster calculations, suggest a partial graphitic surface reconstruction of the diamond nanocrystals.

12:15PM G03.00006: Facile diamond synthesis from lower diamondoids  
SULGIYE PARK, IWINETIM I ABATE, Stanford University, JIN LIU, Center for High Pressure Science and Technology Advanced Research, CHENXU WANG, Stanford University, JEREMY DAHL, ROBERT CARLSON, SLAC - Natl Accelerator Lab, YANG LIUXIANG, Center for High Pressure Science and Technology Advanced Research, VITALI PRAKAPENKA, ERAN GREENBERG, Center for Advanced Radiation Sources, THOMAS DEVEREAUX, Stanford University, CHUNJING JIA, SLAC - Natl Accelerator Lab, RODNEY C. EWING, WENDY MAO, Stanford University, YU LIN (Presenter), SLAC - Natl Accelerator Lab — Carbon-based nanomaterials have exceptional properties that make them attractive for a variety of technological applications. In this talk, I discuss the use of diamondoids (diamond-like hydrocarbons) as promising precursors for laser-induced high-pressure, high-temperature diamond synthesis. The lowest pressure and temperature (P-T) conditions that yielded diamond were 12 GPa (at ~2000 K) and 900 K (at ~20 GPa), respectively. This represents a significantly reduced transformation barrier compared with diamond synthesis from conventional (hydro)carbon allotropes. At 20 GPa, diamondoid-to-diamond conversion occurs rapidly within < 19 us, forming diamond in a range of sizes ~tens of nm to ~4 um crystals, depending on the synthesis conditions. Molecular dynamics simulations indicate that once dehydrogenated, the remaining diamondoid carbon cages reconstruct themselves into diamond-like structures at high P-T. The surprisingly low P-T regime necessary to grow diamond from diamondoids is attributed to the similarities in the structure and bonding of diamondoids and bulk diamond. This study is the first successful mapping of the P-T conditions and onset timing of the diamondoid-to-diamond conversion and elucidates the physical and chemical factors that facilitate diamond synthesis.
First-principles phase diagram of carbon at extreme conditions

KIEN NGUYEN-CONG (Presenter), University of South Florida, ANATOLY BELONOSHKO, Royal Institute of Technology, IVAN OLEYNIK, University of South Florida — The accurate phase diagram of carbon at extreme temperatures and pressures is of paramount importance for design of inertial confinement fusion capsules where diamond is used as an ablator material. In spite of intensive experimental and theoretical efforts, there still exist outstanding problems including disagreement between theoretical predictions and experiment. We present results of first-principles molecular dynamics simulations of thermodynamic properties of carbon at high temperatures and pressures, which are performed with the goal of constructing an accurate phase diagram of carbon. To address the issue of accuracy and reliability, a relatively large number of atoms is used for calculation of melting transitions (melt curve) as a function of pressure using two-phase method. We specifically focus on important region of high pressure, high temperature phase diagram where melt line of diamond exhibits a negative slope, while intersecting the melt line of high-pressure bc8 phase at diamond-bc8-liquid triple point.

Color center qubit formation by local electronic excitation

THOMAS SCHENKEL (Presenter), ARUN PERSAUD, QING JI, SVEN STEINKE, JIANHUI BIN, STEPAN BULANOV, Lawrence Berkeley National Laboratory — Color centers e. g. in diamond are promising qubit candidates. Efforts to find color centers with desired properties, e. g. emission in the telecom bands and long coherence times, are limited by the parameter space in which materials can be processed. Recently, color center formation with fs-laser pulses and using swift heavy ions have been reported. Intense pulses of local excitation can drive materials very far from equilibrium followed by rapid quenching. This extends the parameter range where novel color centers can be formed. We report on mechanisms underlying NV-center formation with swift heavy ions, our search for rare-earth color centers in diamond and new capabilities that we are developing for color center formation far from equilibrium using intense, local pulses of ions and lasers [1-3].

12:51PM G03.00009: Probing the strain field and structural variation in shock-produced amorphous silicon by scanning nano-probe electron diffraction  SHITENG ZHAO (Presenter), University of California Berkeley, ERIC N HAHN, UC San Diego, BRUCE ALLEN REMINGTON, Lawrence Livermore National Laboratory, COLIN OPHUS, BENJAMIN H SAVITZKY, Lawrence Berkeley National Laboratory, CHRISTOPHER WEHRENBERG, Lawrence Livermore National Laboratory, MARC A MEYERS, UC San Diego, ANDREW M MINOR, University of California Berkeley — Shock-induced amorphization can occur when crystalline solids are uniaxially strained in an extremely short time scale. This phenomenon also opens a new door for prototyping the exotic amorphous structures when the conventional methods failed. Taking silicon as an example, we have recovered its amorphous phase from laser shock compression experiments and illustrated the formation mechanisms by both experiments and simulations. However, one missing information is whether the amorphous silicon produced by shock wave is fully relaxed, i.e. are they structurally different than the amorphous structure produced by other techniques such as chemical vapor deposition. We use a newly developed scanning nano-probe electron diffraction technique to tackle this question. A nanometer-sized electron probe is focused onto and rastering over the electron-transparent sample and simultaneously, convergent beam electron diffraction patterns at each pixel are collected, which can be used to compute strain distribution of the region of interest. The strain field in the vicinity of the amorphous band and the radial distribution function within the amorphous domain will be discussed. A tremendous amount of structural variation can be found even within the amorphous domain.

1:03PM G03.00010: Computer Simulations and Experimental Studies on Transition Metal Borides to 390 GPa*  YOGESH VOHRA (Presenter), KALEB BURRAGE, CHRISTOPHER PERREAULT, GOPI K SAMUDRALA, CHIA-MIN LIN, CHENG-CHIEN CHEN, Physics, Univ of Alabama - Birmingham, NENAD VELISAVLJEVIC, HPCAT, Argonne National Laboratory — The attainment of near TPa static pressure in the laboratory has led to a renewed interest in phase transformations and shear strength measurements of incompressible transition metals rhenium (Re), osmium (Os), and their superhard diborides (ReB₂ and OsB₂) We have compressed hexagonal ReB₂, OsB₂, and Os₂B₃ to multi-megabar pressures using Focused Ion Beam machined toroidal diamond anvils. The phase transformations and equation of state were studied using micro-beam angle-dispersive x-ray diffraction at HPCAT beamline 16-BM-D. The platinum pressure marker was employed to the highest pressure of 390 GPa. First-principles simulations based on density functional theory (DFT) were utilized to model ReB₂ and OsB₂ under external pressure. The ambient-pressure lattice parameters computed by the projector augmented-wave method with generalized gradient approximation agree well with the experiment within 1% of error. We will present a comparison of experimental shear strength and equation of state with the elastic constants from DFT calculations up to the highest pressure under study.

1:15PM G03.00011: Thermal stability of silicon carbide  YUEJIAN WANG (Presenter), Physics, Oakland University — A large volume cubic anvil press integrated with synchrotron energy-dispersive X-ray diffraction was employed to study the yielding behavior of powdered beta SiC under high pressure and high-temperature conditions up to 7.4 GPa and 1400°C. During the compression and thereafter heating, x-ray pattern was collected at each pressure-temperature point, and then via assessing the peak width of the X-ray diffraction pattern, the strains/stresses developed inside the sample under varied pressure-temperature conditions was calculated. From the constitutive response of the sample as a function of pressure and temperature, we did not observe the yielding occurrence in SiC at cold compression. In contrast, high temperature induces a yielding at 1100°C with a constant loading pressure ~7.4 GPa. By the comparison, we found that this material is the most stable material, among the other three strong materials (diamond, moissanite, and alfa silicon nitride), in terms of the yielding under high pressure and temperature conditions. Along with its much higher pressure and temperature requirements for phase transition and decomposition, SiC is a competent material to be used in the harshly extreme working environment, such as deep drilling, high-speed cutting, and aerospace engineering.

1:27PM G03.00012: On the strain-rate dependence of dynamic tensile strength in single and nanocrystalline SiC*  WANGHUI LI (Presenter), South China Univ of Tech, ERIC N HAHN, Los Alamos National Laboratory, XIAOHU YAO, South China Univ of Tech, TIMOTHY GERMANN, BIAO FENG, Los Alamos National Laboratory, XIAOQING ZHANG, South China Univ of Tech — The strain-rate dependence of dynamic tensile strength in single and nanocrystalline SiC is investigated via large scale molecular dynamic simulations. A quasi-isentropic loading method is used to evaluate the strain rate to over six-order from \(10^7\) to \(10^{12}\) s\(^{-1}\). SiC with [001] orientation exhibits a perfectly reversible deformation twinning mechanism that enables a high tensile strength, while [110] and [111] crystals contain irreversible defects after unloading that results in a significant decrease in strength. Octahedral cleavage along \{111\} family planes is found to occur only in [001] SiC within \(10^9\) s\(^{-1}\) of the strain rate due to its covalent bond. A power model can be fit basing on the tensile strengths at extremely high strain rate regime which yields a good prediction of strengths at plate-impact experimental strain rates.

G03.00013: High pressure forms of aqueous carbon* NORE STOLTE, ZIXIN CHEN, DING PAN
(Presenter), Hong Kong University of Science and Technology — The chemistry of carbon in aqueous fluids at extreme pressure and temperature conditions is of great importance to Earth's deep carbon cycle. A major obstacle to understanding deep carbon transport is the lack of knowledge of carbon reactions in water at the extreme conditions found in Earth's deep interior. Here, by applying first-principles molecular dynamics simulations, we predicted a few interesting and important carbon reactions in supercritical water, which are dramatically different from what we know at close to ambient conditions. We found that carbonic acid can be the most abundant carbon species in aqueous CO$_2$ solutions at $\sim 10$ GPa and 1000 K. In CO$_2$-rich solutions, significant proton transfer between carbonic acid molecules and bicarbonate ions may enhance the conductivity of solutions. In less oxidized solutions, the reactions of carbon monoxide may participate in the diamond formation.

*The work is supported by the Croucher Foundation through the Croucher Innovation Award and the Sloan Foundation through the Deep Carbon Observatory.

Session G04 DCP DSOFT DPOLY DLS: Coherent Nonlinear Optical Microscopy II 109 - Adrian Pegoraro, Univ of Ottawa - Tag(s): Focus

11:15AM G04.00001: Nonlinear Pump-Probe Microscopy Improves Early Detection of Metastatic Melanoma [Invited] WARREN WARREN (Presenter), DAVID GRASS, MARTIN C FISCHER, XIAOMENG JIA, Duke University — More people die from melanoma after a Stage I diagnosis (localized) than after a Stage IV diagnosis (distant metastatic disease), because the tools available to clinicians do not readily identify which early-stage cancers will be aggressive. We pursue an alternative approach, complementary to conventional histopathology, based on ultrafast pump-probe microscopy. Melanocytes, the neoplastic cells in melanoma, produce a brown to black colored pigment melanin. Analysis of the electronic and vibrational dynamics of melanin with ultrashort laser pulses reveal information like type (pheo, DHI or DHICA eumelanin) and state of aggregation, for example. We use these insights to evaluate primary tumor biopsies with the goal to distinguish between localized melanoma (without metastases) and melanoma that developed metastatic disease. In this talk we focus on our efforts of translating pump-probe microscopy into clinics and our current status on detection of metastatic disease of melanoma.
11:51AM G04.00002: Visualizing molecular structure and function in soft matter using coherent Raman imaging* [Invited] SAPUN PAREKH (Presenter), University of Texas at Austin —
Structure-function relationships define the how molecular processes give rise to macroscopic observables. In this talk, I will present an overview of our recent work using nonlinear vibrational spectroscopic imaging to reveal unique structural-function relationships in polymeric soft matter systems. We have used this imaging technology to map protein structure in fibrin biopolymer networks (that lie at the heart of blood coagulation) and demonstrated that fibrin biopolymers change structure in a spatially heterogeneous manner when exposed to tensile, but not shear, loads. This result hints at a unique self-regulating mechanism via a direct biophysical feedback loop in a physiological context. In another project measuring real-time water transport, we have shown that under-coordinated microscopic water transport and macroscopic proton transport are related in nano-structured polymer fuel cell membranes. From these data, we have proposed a strategy to boost efficiency in fuel cell membrane materials.

12:27PM G04.00003: Correlating Multiphoton-Absorption-Induced Luminescence (MAIL) with Morphology in Noble-Metal Nanostructures* ANNA GRAFOV (Presenter), XIAOYING LIN, Farah Dawood, John T Fourkas, University of Maryland, College Park — The optical properties of nanostructured noble metals differ drastically from those of their bulk counterparts due to surface plasmon (SP) resonance. When incident light couples with the SPs of a noble-metal nanoparticle, it gives rise to strong, localized electromagnetic field enhancement. In particular, surfaces with high curvature experience especially strong field enhancement. Silver and gold SP absorption cross sections lie in the visible region, which make nanostructures of these metals ideal for studying optical phenomena. Multiphoton-absorption-induced luminescence (MAIL) is a nonlinear optical phenomenon that involves ultrafast pulses of light impinging on a nanostructured surface. The SP field enhancement allows for more efficient multiphoton absorption, and highly-efficient, broadband luminescence over the visible spectrum is produced as a result. We examine how the morphologies of noble-metal nanostructures correlate with their MAIL signals. Specifically, we focus on silver nanodendrites, synthesized from galvanic displacement reactions, and gold nanorings and nanotriangles, grown through colloidal synthesis. The absorption order, intensities, and spatial distribution of MAIL signals are examined for different morphologies.

*NSF Grant CMM-11449309
12:39PM G04.00004: Stimulated Raman scattering spectroscopic optical coherence tomography* [Invited] FRANCISCO ROBLES (Presenter), Georgia Inst of Tech — Stimulated Raman scattering (SRS) enables fast, high-resolution imaging of chemical constituents important to biological structures and functional processes in a label-free manner. While this technology has shown remarkable potential, acquisition of SRS signals remains largely limited to point scanning at a few Raman bands. To overcome this limitation, we take advantage of the fact that SRS is a coherent process and can thus be integrated into a single platform with spectroscopic optical coherence tomography (SOCT). SOCT is an extension of OCT that leverages the broadband nature of low-coherent light sources, along with advanced digital signal processing methods, to simultaneously obtain three-dimensional spatial and spectral information, but SOCT has very limited endogenous molecular targets. Thus, the combined approach, termed SRS-SOCT, overcomes limitations of both individual methods and achieves fast, volumetric, and highly sensitive label-free molecular imaging. Here we will present a theoretical framework for SRS-SOCT, discuss its advantages and limitations, and show experimental results from excised tissues.

1:15PM G04.00005: Spectroscopic Fourier-Transform Coherent Raman Microscopy [Invited] MARCUS CICERONE (Presenter), XAVIER AUDIER, WEI-WEN CHEN, RONIT SHARON-FRILLING, Georgia Inst of Tech — Spectroscopic coherent Raman imaging (CRI) methods allow label-free, chemically specific imaging of materials and biological systems, and are opening up many exciting possibilities for understanding phenomena in these systems. I will briefly introduce spectroscopic CRI, specifically broadband coherent anti-Stokes Raman scattering (BCARS), discussing key features required to make these methods practical, current impediments to improvements in speed and sensitivity, and new approaches we are taking to overcome these impediments. I will also present BCARS imaging results that have provided physical insights into biological processes on cellular and organism levels.

Tuesday, March 3, 2020 11:15 AM - 1:27 PM

Session G05 DCP DAMOP DCMP DPOLY: Electronic-Vibrational Coupling in Light Harvesting II. Excitons, Polarons, Perovskites, and Non-Adiabatic Dynamics 111 - David Jonas, University of Colorado, Boulder - Tag(s): Focus
Excitons and polarons play a critical role in the electronic properties of organic molecular aggregates as well as conjugated polymers and aggregates thereof. For many conjugated organic molecules neutral excitations (excitons) and charged excitations (polarons) are coupled strongly to nuclear degrees of freedom involving the symmetric vinyl-stretching mode (i.e. the aromatic-quinoidal vibration when conjugated rings are present). In this talk the photophysical properties of excitons and polarons in conjugated organic materials are compared and contrasted within the framework of a theory based on the Holstein Hamiltonian, which treats local electron-vibrational coupling exactly. Applications are made to excitons in perylene diimide crystals [1] and dopant-induced positively-charged polarons (holes) in poly(3-hexylthiophene) films. [2,3] It is shown how simple optical probes like steady-state absorption and photoluminescence can be used to extract the exciton and polaron coherence lengths, quantities which are important for understanding energy and charge transport.

*This work was supported by the National Science Foundation (DMREF, 1533954).
The spectral line-shape of the mid-IR absorption spectrum provides valuable information about the “hole” polaron coherence length in doped and undoped conjugated polymer films. Using a theory based on the Holstein Hamiltonian for mobile holes in P3HT, the IR line-shape is successfully reproduced for several recently measured spectra recorded in doped and undoped films, confirming the association of an enhanced peak ratio (A/B) with extended polaron coherence. Emphasis is placed on the origin of components polarized along the intra- and inter-chain directions and their dependence on the spatial distribution of disorder and the position of the dopant relative to the π-stack. The model has been further adapted to treat donor-acceptor copolymers.

12:03PM G05.00003: Correlating Structure and Function in Two-Dimensional Organic-Inorganic Hybrid Perovskites [Invited] Cherie Kagan (Presenter), Daniel Straus, Sebastian Hurtado Parra, Qinghua Zhao, James Makato Kikkawa, University of Pennsylvania — Two-dimensional, organic-inorganic hybrid perovskites (2DHPs) are stoichiometric compounds composed of alternating sheets of corner-sharing, metal-halide octahedra and organoammonium cationic layers. We study 2DHPs containing single lead iodide layers separated by intervening substituted, phenethylammonium cations with the chemical structure \((\text{x-PEA})_2\text{PbI}_4\), where \(\text{x}=\text{F}, \text{Cl}, \text{Br}, \text{or CH}_3\). These 2DHPs form type-I heterojunctions in which excitons and carriers are confined to the lead halide layers and strong quantum and dielectric confinement effects establish exciton binding energies that exceed 150 meV. We use powder and single-crystal x-ray diffraction studies, in combination with variable-temperature, steady-state and time-resolved absorption and photoluminescence (PL) measurements to uncover the correlation between their structure and photophysical properties. 15 K spectra of unsubstituted \((\text{PEA})_2\text{PbI}_4\) show splitting of the excitonic absorption and PL into regularly spaced resonances every 40-46 meV. In addition, anti-Stokes hot exciton PL is observed at the same energy as optical absorption resonances. Substitution on the organic cations, for example in the para position, increases the length of the organic cation and therefore the interlayer spacing, but leaves the cross-sectional area for the organic cation unchanged and results in structurally similar metal halide frameworks. As the length of the cation increases in the 2DHP, the absorption spectra broaden and blueshift, but the PL spectra remain invariant. We show that the excitonic structure is consistent with strong electron-phonon coupling and slow vibrational relaxation originating from the softness of the metal halide framework and the organic cations.

12:39PM G05.00004: Investigating how biological membrane parameters influence the ring opening of Provitamin D Danielle Sofferman (Presenter), Roseanne J Sension, Univ of Michigan - Ann Arbor — Ultrafast photochemical transformations of 7-Dehydrocholesterol (DHC, Provitamin D\(_3\)), DHC-Acetate and Ergosterol (Ergo, Provitamin D\(_2\)) to previtamin (D\(_3\), D\(_3\)-acetate and D\(_2\)) occurs upon a ring-opening reaction in the excited state where a Cyclohexadiene (CHD) chromophore embedded within the molecules opens to form a previtamin D species. In isotropic environments, the ring opening reaction occurs within 1-2ps therefore it is necessary to use ultrafast techniques such as transient absorption to capture the kinetics. However, in the lipid bilayer this reaction is slowed to 11ps. Here we are studying DHC and its analogs in lipid bilayers as a simple model for biologically relevant skin membrane models. To investigate the 6 fold slow down, the ring opening of DHC will be discussed in terms of lipid properties such as Van der Waals interactions, Hydrogen Bonding and membrane ridgidity.
Superradiance of two-dimensional molecular aggregates* [Invited] ALEX EISFELD (Presenter), Max Planck Institute for the Physics of Complex Systems — Assemblies of molecules (so-called molecular aggregates) have become versatile quantum systems with applications in photography, opto-electronics, solar cells, and photo-biology. The remarkable properties of these aggregates stem from the strong transition dipole-dipole interaction between the individual molecules which leads to eigenstates with excitation shared coherently by a large number of molecules. As a consequence the aggregate possesses strikingly different optical properties compared to the individual molecules.

In this talk I will discuss the superradiant emission of organic molecules arranged on dielectric surfaces. A particular focus is on the relation between the temperature dependence and the underlying eigenfunctions of the aggregate [1]. Knowledge about these eigenfunctions is not only important to understand the optical properties but also for the transfer characteristics of the aggregates. Optical spectroscopy, in principle, allows one to infer information on these eigenstates and about the interactions between the molecules. However, traditional optical techniques using an electromagnetic field which is uniform over the relevant size of the aggregate cannot access most of the excited states because of selection rules. We demonstrate that by using localized fields and machine learning techniques one can obtain information about these otherwise inaccessible states. As an example, we discuss in detail the case of local excitation via radiation from the apex of a metallic tip, which allows also scanning across the aggregate. The resulting spatially resolved spectra provide extensive information on the eigenenergies and wave functions [2,3].

*Grant No EI 872/5-1 (Heisenberg fellowship) from the German Research Foundation (DFG)

A resonant confinement of polariton under strong photon-exciton coupling is predicted to exist within the microcavity of the crystals own natural boundaries. Moreover, the radiative energy of a localized exciton falls into the spectrum of the confinement.

The spontaneous emission of an excited pigment would undergo a two-step process. It should first decay to an excitonic polariton trapped by the cavity resonance. The captive intermediate could then funnel the energy directly to doped acceptors, leading to the observed over 90% transfer efficiency at less than 1/1000 acceptor-donor ratio.

The proposed mechanism is supported by parameter-free analyses entirely based on experiment data. Our finding may imply possible polariton-mediated pathways for energy transfers in biological photosynthesis.

*This work was supported in part by the National Natural Science Foundation of China No. 16Z103060007 (P.A.).
11:15AM G06.00001: Breaking Down Barriers to Science and Physics Communication in China - Do Veritasium YouTube Videos Translate?  
HANYU ZHANG (Presenter), Applied and Engineering Physics, Cornell University, DEREK MULLER, Veritasium — Educational content on YouTube has seen incredible growth and gotten significant traction. Physics-focused YouTube channels are no exception. From the earliest days of education on YouTube, Veritasium [1,2], an educational physics YouTube channel now with over 6 million subscribers and 650+ million views, has educated and engaged the general public about physics.

However, due to political barriers, Veritasium and other YouTube channels are blocked in China. This energy barrier, although significant, is not insurmountable. Veritasium has recently become one of the first YouTube channels to fully overcome the language, cultural, and political barriers and step into China. With close to 50 thousand subscribers and 2 million views on a Chinese platform, Veritasium has demonstrated that accessible physics education content can also go viral in China. This realization leads to an opportunity for anyone interested in making an impact in physics education to do so anytime anywhere with simple code and existing content.

[1] YouTube channel: youtube.com/veritasium  

11:27AM G06.00002: Physics to Environmental Science: Solution Seeker of today’s world  
LIBIA HAZRA (Presenter), N. SRINIVAS, Gandhi Institute of Technology and Management — In this talk I share my journey as a solution-seeker to restore the natural state of our environment as I move from an agriculture-based society into studying physics and then switching into environmental science to help develop a sustainable environment and a culture of high-yielding organic farming. As I prepare to work on using satellite images to help benefit agriculture, ecotoxicology, environmental chemistry, and controlling salt-water intrusion, I realize at every step that application of Physics concepts is quite an integral part of Environmental science. I will discuss how my background in Physics, Maths and Chemistry gives me strength to better understand the current topics in environmental science as I aspire to apply my natural aptitude for instruments and experiments to estimate the pollutants in our air, water, land and food and want to invent and implement feasible solution to better the health of all living being and mother earth.
For students with environmental mind-set (future environmentalists), I strongly suggest for a thorough foundation in Physics, Maths, Chemistry and Computer Science to be better equipped in tackling the towering task that an environmentalist have to do.
**11:39AM G06.00003: Share your research at FunSize Physics**  
SHIREEN ADENWALLA (Presenter), JOCELYN BOSLEY, University of Nebraska - Lincoln, LEIGH M SMITH, Physics, University of Cincinnati — www.funsizephysics.com is a colorful, user-friendly website created in Spring 2016 with the express purpose of showcasing exciting new developments in condensed matter physics to a broad audience of non-experts. The research descriptions are written by the researchers themselves, serving as an efficient, low bar broader impact activity in a PI's portfolio. Google Analytics allows researchers to quantify the impact of their contributions, tracking the number of views, stars, thumbs up and viewing time. We have optimized the existing website to make it more user-friendly and made a short video advertising the website. In addition, by making the website a convenient place in which to collaborate and discuss a variety of outreach efforts, it serves as a resource for NSF PIs to develop best practices for outreach activities to K-12 students and the general public. We invite contributions from students, post-docs and faculty-share your beautiful, ground breaking science with a wider audience, discuss the advantages and disadvantages of your outreach activities-make it yours!

*Funded by NSF-DMR-1725823*

**11:51AM G06.00004: Physics outreach as teaching and service-learning experience for students**  
TATIANA ERUKHIMOVA (Presenter), Texas A&M University — We will present the results of an innovative program at Texas A&M University that aims to add hands-on, teamwork, and outreach components to the learning and research experiences of undergraduate and graduate students. In this program, undergraduates taking introductory physics classes work throughout the school year in small teams led by physics graduate students on design and fabrication of exciting physics demonstration experiments: from a giant Galilean cannon to liquid sand pool, Texas-sized Tesla coil, superconducting train, and supersonic gun. Student teams demonstrate their experiments at high-profile outreach events such as the Texas A&M Physics & Engineering Festival, Physics Shows, Just Add Science, and Game Day Physics. They film their experiments in 2-3 min video clips posted at realphysicslive.com. The demonstrations are also used in regular physics classes at Texas A&M.

**Tuesday, March 3, 2020 11:15 AM - 2:03 PM**

Group Exam as an Instructional Technique to Promote Consistency Checking in Student Reasoning

ALISTAIR MCINERNY (Presenter), LIOUDMILA KRYJEVSKAIA, Physics, North Dakota State University — Many students tend to provide intuitively appealing (but incorrect) responses to some physics questions despite demonstrating (on similar questions) the formal knowledge necessary to reason correctly. While these inconsistencies are typically persistent even in active learning environments, we believe that adding a group component to the exam may engage students sufficiently to resolve these instances of inconsistent reasoning. In our study, students were given opportunities to revisit their answers to questions known to elicit strong intuitively appealing (but incorrect) responses in a collaborative group component of an exam immediately following a traditional individual component. Students discussed their responses with group members but were required to submit their own answers and reasoning. In this presentation, we will examine the effectiveness of a collaborative group exam approach in addressing and resolving inconsistencies in student reasoning and will compare the effectiveness of this approach to a more traditional peer instruction technique.

This material is based upon work supported by the National Science Foundation under Grants Nos. DUE-1821390, DUE-1821123, DUE-1821400, DUE-1821511, DUE-1821561, DUE-1431940, DUE-1431541, DUE-1431857, DUE-1432052, and DUE-1432765.

Developing the First Two Years of an Undergraduate Physics Program - A Ten-Year Study

EFFROSYNI SEITARIDOU (Presenter), Physics and Astronomy, Oxford College of Emory University — Oxford College (OC) is an undergraduate division of Emory University focused on the liberal arts education of 950 first- and second-year students. After their second year, the students move to Emory College (EC) to complete the remainder of their undergraduate education. Between 2008-2010, OC contributed only 5 physics majors to the graduating classes at EC. To expand student interest in first- and second-year physics courses and increase its contribution to the number of physics majors OC applied many strategies, including those recommended by the National Task Force of the American Association of Physics Teachers [1]. The strategies focused on creating a rigorous curriculum and an environment and evaluation process to meet the students’ individual needs. Among the outcomes were that between 2010-2019 the physics faculty grew from one to three, the enrollment of women in a sophomore-level course increased from 17% to 38%-50%, and OC’s contributions to the total number of EC’s physics majors increased to 19 in years 2017-2019. An additional 13 students are estimated to graduate in 2020 alone. This presentation will provide an overview of the applied strategies and their outcomes.

11:39AM G07.00003: “Not Required,” “No Required Minimum,” and “Optional” General and Physics GRE Requirements: The Impact on Prospective Graduate Students* LINDSAY OWENS (Presenter), BENJAMIN M ZWICKL, CASEY MILLER, Rochester Institute of Technology — When applicants search for graduate schools, they research multiple aspects of the programs and reflect on how well they envision themselves fitting into each program. Graduate program’s reported Physics and General GRE requirements, recommended minimum scores, and previous cohort score averages influence students’ decisions about where to apply. In recent years, the test-optional language of No Required Minimum and GRE Optional requirements has muddied the waters for prospective applicants, particularly for women. In this qualitative study, 54 graduate students (25-F; 27-M; 2-DND) from 23 different graduate programs were asked how they decided where to (and not to) apply to graduate school. All students felt welcome to apply to graduate programs whose admissions requirements stated GRE Not Required or Do Not Send. However, women were far less likely than men to apply to graduate programs that stated No Required Minimum or GRE Optional language on their admission requirements webpage. This talk will highlight (1) how students interpreted these phrases, (2) how such phrases influenced students’ self-reflection about fit, and (3) how these factors influenced their decision on where to apply to graduate school.

*Supported by NSF-1633275

11:51AM G07.00004: Solid State Physics across the Undergraduate Curriculum ANDRA PETREAN (Presenter), Austin College — Solid state physics encompasses a variety of physics phenomena, including modern ones such as high temperature superconductivity and nanotechnology. Despite its appeal, teaching it at undergraduate level can present challenges, as students may not have the necessary physics background until late in their undergraduate studies. Faculty at small physics departments often need to teach a range of courses, spanning from courses for the physics majors to service courses for the larger student body, and hence they may not be able to offer solid state physics as an elective. In this context, I will present the approach I took at Austin College, a small liberal arts school, in incorporating solid state physics in our curriculum, from our first-year course to capstone projects. I have used theoretical, experimental, lecture-based and project-based approaches. The topics included superconductivity through synthesis and characterization of high temperature superconductors, and nanotechnology through synthesis of carbon nanotubes and deposition and characterization of thin films at nanoscale.

12:03PM G07.00005: New Methods for the Advanced Lab RUDI MICHALAK (Presenter), Univ of Wyoming — The advanced lab lives at the awkward intersection of irrelevance and capstone course. I contend that it has a big part to play in the future of physics education and that it can be instrumental in turning undergraduate majors into professional physicists and astronomers. Tools that can be developed and which can convince lower and higher administration to invest into costly equipment include: Embedding of lab goals into institutional goals, assessment, and career outcomes. Cultivating critical thinking and presentation skills. Creating belonging and rapport that appeals to minorities. Reinvigorating tired out majors into this-is-what-I-came-here-for mindsets.
12:15PM G07.00006: A Single-axis Tunneling Microscope for Undergraduate Labs  RANDY LINDGREN, JOSHUA VEAZEY  (Presenter), Grand Valley State University —
I will discuss the conception and development of a low-cost z-axis tunneling microscope (ZTM) for learning about quantum mechanics and electronic structure in undergraduate labs. Inspired by the scanning tunneling microscope, this device cuts costs and complexity for the undergraduate lab setting by limiting tip control to the tip-sample separation. To further reduce cost, an off-the-shelf ceramic capacitor (MLCC) is used as the piezo actuator [1]. Students can observe the exponential dependence of the tunneling current on barrier width ($I-z$), as well as the local electronic density of states ($I-V$) for many samples under ambient conditions.

12:27PM G07.00007: The Tolman-Stewart Experiment – A Modern Interpretation  JOSHUA SCHMIDT  (Presenter), MATTHEW C. SULLIVAN, Ithaca Coll — The Tolman-Stewart Experiment, published in 1916 by Richard C. Tolman and T. Dale Stewart, proved that the charge carriers in a conductor were identical to the electrons previously discovered in cathode rays and beta rays. The concept of free electrons in a conductor is still an essential building block of electrodynamics, and the Tolman-Stewart experiment demonstrates this in a fundamental way. Our interpretation of this experiment makes use of modern circuitry and computer control to better adapt the experiment for an advanced undergraduate lab course. We spin a coil of copper or aluminum wire up to sufficiently high speeds and brake it suddenly. This stops the nuclei, but the free electrons keep moving, creating a short-lived current pulse. This current pulse is amplified, converted to a voltage, and recorded using a simple circuit and data acquisition system. Modern rotational encoders accurately determine the rotational speed. Our results confirm that the charge carriers inside both copper (negative charge carriers via the Hall Effect) and aluminum (positive charge carriers via the Hall Effect) are electrons. This interpretation brings a canonical experiment to the advanced lab for the first time and yields compelling proof of the identity of charge carriers in a conductor.
12:39PM G07.00008: Statistical differences in over 1000 Student Lab Reports and 9000 Lab TA comments using new Experimental Design Pedagogy*  DAVID MCKENNA, ABIGAIL MECHTENBERG (Presenter), University of Notre Dame — At a rate of 700+ students/year implementation of this experimental design (ED) pedagogy, 4.5 years of data was collected. This ED pedagogy moves the lab culture from cookbook labs into inquiry-based deviations, and towards a research-based final project. Three ED thought spheres scaffold all labs into cookbook-based pattern recognition: measurements (M), calculations (C), and variations (V). Three ED connection pathways teach students how, when and why scientists critically think about doing science (regression versus derivation approaches) using 3 interconnected stages Design, Data, and Analysis. With Google Classroom, Lab TAs wrote feedback comments as well as the rubric-based grades for student lab reports in one term alone. We analyzed all comments in terms of total words, tone, complexity, and probing level. It was hypothesized that the tone of Lab TA comments were correlated to student evaluations; however, it was complexity, word count, and probing level of comments which were correlated to student evaluations (and final exam scores). We discuss future research into the differences between Teaching/Learning pair types: Judging Teacher and Obedient Student (Active-Reactive) versus the Socratic Teacher and Constructive Student (Reactive-Active).

*Physics ND Seed Funding

12:51PM G07.00009: The Wolfram Language: A general tool for science education  JASON MARTINEZ (Presenter), Wolfram Research — The Wolfram Language (WL) provides a wide range of scientific data, tools, and algorithms for students of all levels. The WL includes an extensive knowledge base on subjects from the properties of subatomic particles to the details of orbits to the changing magnetic field of the earth. Students can engage with the WL in a wide range of formats. They can start out with simple natural language queries on Wolfram|Alpha, getting guidance on solving complex equations using its step by step functionality. Through the Wolfram Demonstrations Project, they can find thousands of dynamic examples for a wide range of physics concepts. In Wolfram|Alpha Notebook Edition students turn their natural language queries into actual code as well as make use of the Wolfram Function Repository which expands the WL with specialized independently submitted functions. Using the WL fully students can manipulate formulas with explicit units and physical quantities, propagate uncertainty in their calculations, compute eigenvalue and vectors, use advanced tools to solve ODEs and PDEs, analyze results using statistical models, create dynamic and insightful visualizations, employ machine learning algorithms, and utilize a wide range of other computational tools.
**1:03PM G07.00010: Relating to Students via Simulation of Cutting Edge Experimental Physics (Virtual RIXS)**  
TODD HOLDEN (Presenter), Physics, Queensborough Community College of CUNY — In contrast to other fields, it is difficult to satisfactorily explain the work of a modern day research physicist to an undergraduate physics major, even after the sophomore year. This is in large part because quantum mechanics is abstract, difficult, and counterintuitive. As part of a pilot project to address these issues, we present a PhET-based spectroscopy simulator (viewable at https://heldentodd.github.io/phetsims/RIXS-simulator/RIXS-simulator_en.html) and some related pedagogical materials for formal and informal education. Currently the simulator is geared toward exploring discoveries enabled by the recent advances in resonant inelastic x-ray scattering (RIXS). This allows us to introduce ideas in advanced materials physics (electronic properties) to second year physics students as part of their mainstream curriculum, as well as to give students a better idea of modern physics research. Emphasis has been placed on developing basic concepts such as energy, momentum, electric fields, and elementary quantum physics. Student and instructor reaction to this project will be discussed, along with future education and dissemination projects aimed at both higher and lower level students.

**1:15PM G07.00011: Controlled Studies of Stereoscopic Virtual Reality in Freshman STEM Classes**  
JONATHAN BROWN (Presenter), CHRISTOPHER D PORTER, JOSEPH R SMITH, CHRIS ORBAN, Ohio State Univ - Columbus — Stereoscopic virtual reality (VR) driven by smartphones is a relatively new tool for teaching concepts that rely on detailed three-dimensional visuospatial skills. VR has long been a topic of education research, and smartphone-driven VR significantly reduces the barrier to entry for both students and instructors and can be implemented for all students at once in the classroom. However, best practices for effective VR implementation are needed. To this end, we implemented VR interventions for freshmen physics, math, and engineering classes at OSU. In the physics course, our electrostatics VR module covered vector fields. Initially, we compared VR to traditional media, and in a follow-up study, we found that training in VR can have a small but significant effect on learning gains during a VR treatment. In a multivariate calculus course, students chose between various media for viewing content. In the engineering visuospatial thinking course, we found small gains when comparing modules with and without VR treatments. Overall, we find that VR is an effective tool for increasing student engagement, but that learning gains, when present, do not seem to depend on medium. Instead, a key factor is that students have a choice to use media that they are comfortable with.
1:27PM G07.00012: Virtual Reality Simulations for Solid State Physics Education  JAMILEH BEIK MOHAMMADI (Presenter), JOHN SEEFELDT, Loyola University New Orleans — Solid-state physics is considered hard to grasp since it requires a strong background in math and quantum mechanics. Even with a solid knowledge of math and quantum mechanics, it is still challenging to visualize the three dimensional and even complicated two-dimensional structures. In the meantime, the spatial visualization of crystals is critical to understand the symmetries of a physical system.

We have utilized virtual reality simulations to improve the students' spatial visualization ability and help them to have a more interactive learning experience in a solid-state physics context. In this talk, I will present on the details of how virtual reality simulations are used as a virtual lab [1] to build different types of crystals and associate the lattice structure with the physical properties such as magnetic and electronic properties of solids.

1:39PM G07.00013: Teaching Women's History in Physics  BETH PARKS (Presenter), Physics and Astronomy, Colgate University — Much effort has been expended to uncover contributions by women in physics and publicize examples of female physicists to students, largely to help female students see themselves in physics. However, the physicists who formulated the ideas taught in college courses were almost all men, and women's absence from these important roles will be noted by students. If we don’t acknowledge and address their absence, then female students won't feel fully supported in their decision to become physicists, since they'll see women only in less influential roles. We need to discuss the social context in which these most influential physicists worked. Since the necessary combination of educational opportunities, family support, social acceptance, financial means, and employment opportunities were available to a much smaller fraction of women than men, it's no surprise that a small fraction of discoveries were made by women. This talk will present a brief sampling of history, looking at the opportunities of three important male physicists—James Clerk Maxwell, Robert Millikan, and Albert Einstein—and comparing them to their female peers. Instructors might use a few minutes of class time to discuss this disparity, and simultaneously open the door to discussions of current social conditions.
Students in physics classes have the skills and background to add high-quality content to Wikipedia while gaining depth of knowledge about the subject and taking ownership of their learning experience. Since 2014, university students in physics and engineering classes have added over 400,000 words to Wikipedia articles using tools and support provided by Wiki Education, a nonprofit organization dedicated to improving Wikipedia's quality, equity, and reach. These articles were viewed over 7.5 million times in the semesters in which the students were active.

We will discuss our experience running assignments (Vershinin) and the overall impact of the program (Ramjohn). Attendees will gain insight into the benefits of trying this assignment in their courses, and will leave with information about getting started.

Tuesday, March 3, 2020 11:15 AM - 1:15 PM

Session G10 GIMS: Detectors, Sensors, and Transducers 108 - Roger Proksch, Asylum Research

11:15AM G10.00001: Semiconductor Particle Detector based on Work Function Modulation*

ELAINE RHOADES (Presenter), WILLIAM HUNT, AARON GREEN, Georgia Inst of Tech — A novel type of solid state particle detector has been designed and investigated. The essential design is a bandgap reference circuit with a Schottky diode comprised of gallium nitride, a semiconducting piezoelectric material, designed to output the Schottky barrier height. As a semiconductor, this material exhibits an electrical response to high-energy particle impingement through the creation of electron-hole pairs. It also exhibits an additional and very unique type of response to lattice vibrations induced in the crystal lattice by momentum transfer from the incident particle. These acoustic waves create mechanical strain which induces an in-phase signal via the piezoelectric effect, which subsequently modulates the effective barrier height of the Schottky diode. This talk presents functional demonstration of a prototype circuit and transient responses to neutron irradiation.

*This material is partially based upon work supported by the U.S. Department of Energy, Office of Science, Office of Workforce Development for Teachers and Scientists, Office of Science Graduate Student Research (SCGSR) program. The SCGSR program is administered by the Oak Ridge Institute for Science and Education (ORISE) for the DOE. ORISE is managed by ORAU under contract number DE-SC0014664.
11:27AM G10.0002: Characterization of Micro-Magnets on Mechanical Oscillators, and Other Sensors Using Fiber-Optic Interferometry*  
PETER W. KAMPSCHROEDER (Presenter), SIERRA M CASTEN, NIMISHA RAMPRASAD, ALLEN C. WEN, SCOTT S. WILLIAMS, JOHN T. MARKERT, Department of Physics, The University of Texas at Austin — We report the design, construction, and use of a fiber-optic interferometer system with variable applied dc and ac magnetic fields and magnetic field gradients for the characterization of micro-magnets on oscillators. The system has measured calibrated displacements to determine resonant frequencies (~1–800 kHz), quality factors (~100–8000), amplitudes, and spring constants (~0.01 N/m) of resonances. Thermal-noise-driven data determined spring constants. The driven response to ac magnetic field gradients (amplitudes ~0.4–40 x10⁻⁴ T/m) provided direct measurement of magnetic moments. E.g., for a ~45±5-µm-diameter permalloy sphere, we measure a magnetic moment of 2.8±0.1 x10⁻⁸ J/T, in agreement with the expected saturation moment of 3.1±0.6 x10⁻⁸ J/T. Characterization of these micro-magnets supports our nuclear magnetic resonance force microscopy (NMRFM) studies. In addition to NMRFM, other ongoing work involving fiber-optic interferometry includes its use in integrated, narrow (~0.2–2 mm Φ) oscillator-fiber sensors for placement in thin channels (e.g., for fast, local quench detection) and its use in a fast-response pressure sensor for operation under extreme (jet/rocket engine) conditions.

*Support from University of Texas, College of Natural Sciences Freshman Research Initiative.

11:39AM G10.00003: Secondary Electron Count Imaging in a Scanning Electron Microscope*  
AKSHAY AGARWAL (Presenter), JOHN SIMONAITIS, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, VIVEK GOYAL, Department of Electrical and Computer Engineering, Boston University, KARL BERGGREN, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology — We have implemented secondary electron (SE) count imaging on a Zeiss LEO 1525 scanning electron microscope (SEM). We established the signal level of single SEs using two methods – image histograms and oscilloscope outcoupling. In both methods, we imaged a uniform sample of aluminum at low beam currents (< 5 pA) and pixel dwell times between 500 ns and 7 µs using both the in-chamber and in-lens SE detectors. In the first method, histograms of the sample images showed distinct peaks corresponding to the number of SEs emitted from each pixel. We used these peaks to establish the single SE signal level and calculated the detective quantum efficiency of our detectors. In the second method, we outcoupled the signal from our SE detectors to a 2 GHz oscilloscope. The output signal trace showed a sequence of pulses of mean duration 180 ns, corresponding to single SEs. Histograms of the total area of the output signal matched the image histograms for the same pixel dwell time. Finally, we synchronized data capture on the oscilloscope with the SEM scan signal to generate SE count images, which showed an improved signal-to-noise ratio compared to conventional images.

*We acknowledge funding from the Gordon and Betty Moore Foundation and the U.S. NSF under Grants 1422034 and 1815896.
11:51 AM G10.00004: Bio-Inspired MEMS Direction Finding Underwater Acoustic Sensor Operating in Neutral-Buoyant Configuration* LELAND MCCARTY (Presenter), JAEHYUN PARK, FABIO ALVES, GAMANI KARUNASIRI, The Naval Postgraduate School — MEMS acoustic sensors were developed based on the mechanically coupled auditory structure of the *Ormia Ochracea* fly in order to enhance underwater directional sound-sensing technologies. MEMS directional acoustic sensors consist of two wings connected by a bridge in the middle. The entire mechanical structure is connected to a substrate using two torsional legs. The mechanical vibrations under sound excitation is transduced to an electrical signal using interdigitated comb finger capacitors attached to the edges of the wings. This presentation covers the design, fabrication, and characterization of *Ormia*-based MEMS directional acoustic sensor operated underwater as an inertial sensor. The sensors were designed using FE modeling tools and fabricated using commercially available MEMSCap SOIMUMPS processes. Characterization was performed in air and underwater, showing the predicted frequency and directional responses. For underwater operation, the sensors were housed in a near-neutral-buoyant, hermetically sealed enclosure. Results indicate that the MEMS acoustic sensor’s microphone characteristics are preserved when operated as accelerometers, and they have a great potential to be used for underwater applications in a neutral-buoyant configuration.

*Supported by ONR.

12:03 PM G10.00005: New system for high sensitivity study of magnetoelectric effects* ALI SIRUSI, MARC LEWKOWITZ (Presenter), JOHNNY ADAMS, RUYANG SUN, NEIL SULLIVAN, Department of Physics and The Center for Molecular Magnetic and Quantum Materials, University of Florida — We report a novel experimental technique for studying magnetoelectric couplings in matter using a tunnel diode to power a specially designed coil cell. The system can detect small changes in frequency of 0.5 ppm, allowing precise measurement of magnetic susceptibility induced by an applied electric field. This system operates over a temperature range from 1.8 K to 100 K, while maintaining the tunnel diode at superfluid helium temperature. The aim of this device is to study magnetoelectric couplings in molecular magnets and spin crossover systems.

*This work was supported as part of the Center for Molecular Magnetic Quantum Materials, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award DE-SC0019330.
12:15PM G10.00006: Performance of superconducting nanowire single photon detectors in strong magnetic fields

TOMAS POLAKOVIC (Presenter), Physics Division, Argonne Natl Lab,
VOLODYMYR YEFREMENKO, High Energy Physics Division, Argonne Natl Lab, JOHN PEARSON, Materials Science Division, Argonne Natl Lab, WHITNEY ARMSTRONG, ZEIN-EDDINE MEZIANI, KAWTAR HAFIDI, Physics Division, Argonne Natl Lab, GORAN KARAPETROV, Department of Physics & Department of Materials Science and Engineering, Drexel University, VALENTYN NOVOSAD, Materials Science Division & Physics Division, Argonne Natl Lab — Superconducting nanowire single photon detectors (SNSPD) have found applications in many fields, including nanophotonics, quantum communication and computing. There is potential in applications in high energy physics, but operation in high magnetic fields is required.

We study the performance of SNSPDs in high magnetic fields by implementing superconducting type-II materials with high upper critical fields and critical currents. Using the recently developed ion-beam assisted sputtering method[1], we fabricate Niobium Nitride SNSPDs on non-epitaxial substrates using a two-step process, and perform optoelectronic characterization across a wide range of magnetic fields. We demonstrate performance with zero dark counts and saturated internal quantum efficiency in fields of up to 8 T for visible wavelength photons with no need for changes to the common meander geometry[2].

*This work was supported by the U. S. Department of Energy (DOE), Office of Science, Offices of Nuclear Physics, Basic Energy Sciences, Materials Sciences and Engineering Division under Contract # DE-AC02-06CH11357.
A portion of this work was conducted at the Center for Nanoscale Materials, a U.S. Department of Energy, Office of Science (DOE-OS) user facility.

12:27PM G10.00007: High Sensitivity Photodetector Based on Graphene-Germanium Quantum Dot

YIFEI WANG (Presenter), HO VINH, PRASHANT PRADHAN, DANIEL SEITZ, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech, MICHAEL P. COONEY, NASA Langley Research Center, VINH Q NGUYEN, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech — Graphene has shown great potential for realizing optoelectronic devices, especially for photodetectors. Here, we experimentally demonstrate a fabrication of photodetector based on graphene-germanium quantum dots that can detect a broadband spectrum from visible to infrared region. The device, based on graphene-germanium quantum dots, demonstrates an improved responsivity and response time. Characteristically, the fabricated photodetector shows a responsivity of 1,500 A/W at room temperature and a fast photoresponse time in the order microseconds. The results address key challenges for broadband photodetectors in the visible to infrared region, and also are promising for the development of graphene-based optoelectronic applications.

*Supported by the Earth Science Technology Office (ESTO), NASA
Advanced thermal readout techniques for ac voltage metrology

JOSEPH HAGMANN (Presenter), NIKOLAI KLIMOV, JASON M UNDERWOOD, STEFAN CULAR, National Institute of Standards and Technology — One of the most accurate methods for quantifying ac voltage amplitude to compare the rms amplitude of an ac waveform to an equivalent dc voltage using a device called a multi-junction thermal converter (MJTC). The MJTC produces a dc output voltage in response to the temperature rise from Joule heating due to electrical power dissipation in a resistive heater. The uncertainty of an MJTC measurement is about 1 µV/V (1 ppm) for voltages in the range of 0.5 V to 10 V and frequencies in the range of 40 Hz to 20 kHz. Conventionally, the rise in temperature due to Joule heating is measured on the MJTC by an array of thermocouples. Although well-established, this type of readout suffers is made challenging by the relatively large resistance (~10kΩ) of the thermocouple array, and the low (several mV) thermovoltage. Here, we present our research into alternative measurement techniques based on physical phenomena such as infrared emission, superconductivity, and photonics in order to achieve improved stability and sensitivity and to extend the voltage and frequency range in which the measurement is accurate, bridging fundamental research with the engineering problems of harnessing useful physics to achieve advanced measurement technology.

Measurement of Alzheimer’s Enzymes at Physiological Concentrations with Solid-State Dual-Gate 2D-MoS2 Transistors

SON LE (Presenter), NIST & Theiss Research, NICHOLAS B. GUROS, National Institute of Standards and Technology, NIRANJANA AMIN, HARISH C PANT, National Institutes of Health, ARVIND BALIJEPALLI, CURT RICHTER, National Institute of Standards and Technology —

We have developed sensors based on ionic liquid gated field-effect transistors (FETs) operating at the quantum capacitance limit that allow ultrasensitive pH measurements for biophysics applications [1]. To improve the durability and accessibility of the devices for the broader biological research community, we have recently developed a solid-state version of these high-performance devices and applied it to measure the activity of enzymes relevant to Alzheimer’s disease. The FETs are fabricated with a single-monolayer of the 2D transition metal dichalcogenide MoS2 and are top-gated with a high-k dielectric gate oxide. The asymmetric capacitive coupling between the high- k top-gate and the back-gate dielectric (substrate oxide) enables amplification of a voltage applied to the top gate by up to a factor of 8. We leveraged the high performance of the devices to enable pH measurements with sensitivities that exceed the Nernst value of 59 mV/pH at room temperature. The improved sensitivity allows the detection of pH changes as small as 0.004. We demonstrate that this enhanced sensitivity facilitates the measurement of activity and kinetics of enzyme-catalyzed phosphorylation of substrate proteins at physiological concentrations.

1:03PM G10.00010: Twin slot antenna coupled graphene THz heterodyne mixer*  
JAYAPRAKASH POOJALI (Presenter), FRANCOIS JOINT, ASHRAF ALI, KEVIN DANIELS, THOMAS E. MURPHY, HOWARD DREW, University of Maryland, College Park — The unique hot electron properties of graphene make it an ideal platform for terahertz (THz) heterodyne mixers. However, prior graphene-based heterodyne mixers are designed to operate at cryogenic temperatures and show poor performance above 4 K. In this work, we describe the design of a room temperature graphene based heterodyne mixer optimized to work in the THz spectral range of interest to space based astronomy. The proposed mixer is coupled to a twin slot antenna and a coplanar waveguide transmission line with an impedance matching network. Numerical simulation predicts that the coupling efficiency of the incoming radiation to the graphene mixer is over 90% at 1 THz. The mixer has a predicted intermediate frequency bandwidth of 100 GHz with 90% coupling efficiency. Further, the proposed optimized antenna can match graphene device impedances from 70 Ω – 250 Ω by optimizing the slot width of the antenna. Epitaxial grown quasi-free-standing graphene on silicon carbide substrate was used and it is integrated with a silicon lens. We are currently characterizing the IF mixing bandwidth of our heterodyne mixer at various temperatures and plan to calibrate its sensitivity.

Tuesday, March 3, 2020 11:15 AM - 1:15 PM

Session G15 DFD DSOFT: Active Colloids I 210/212 - Arvind Gopinath, University of California, Merced

11:15AM G15.00001: Active Microrheology, Hall Effect, and Jamming in Active Chiral Fluids
CYNTHIA REICHHARDT (Presenter), CHARLES REICHHARDT, Los Alamos Natl Lab — We examine the motion of a probe particle driven through an active chiral fluid composed of circularly swimming disks. We find that the probe particle travels in both the longitudinal direction, parallel to the driving force, and in the transverse direction, perpendicular to the driving force, giving rise to a Hall angle. Under constant driving force, we show that the probe particle velocity in both the longitudinal and transverse directions exhibits nonmonotonic behavior as a function of the activity of the circle swimmers. The Hall angle is maximized when a resonance occurs between the frequency of the chiral disks and the motion of the probe particle. As the density of the chiral fluid increases, the Hall angle gradually decreases before reaching zero when the system enters a jammed state. We show that the onset of jamming depends on the chiral particle swimming frequency, with a fluid state appearing at low frequencies and a jammed solid occurring at high frequencies.
11:51AM G15.00002: Hydrodynamic Spin Lattices* PEDRO J SAENZ (Presenter), UNC Chapel Hill, GIUSEPPE PUCCI, Institut de Physique de Rennes, SAM E TURTON, RUBEN R. ROSALES, JORN DUNKEL, JOHN W M BUSH, MIT — In this talk, we introduce hydrodynamic spin lattices (HSLs) of walking droplets as a new class of highly tunable active spin analog systems. Millimetric liquid droplets can walk across the surface of a vibrating fluid bath, self-propelled through a resonant interaction with their own guiding wave fields. A walking droplet, or walker, may be trapped by a submerged circular well at the bottom of the fluid bath, leading to a clockwise or counterclockwise angular motion centered at the well. When a collection of such wells is arranged in a 1D or 2D lattice geometry, a thin fluid layer between wells enables wave-mediated interactions between neighboring walkers. For sufficiently strong pair-coupling, wave interactions between neighboring droplets may induce local spin flips leading to ferromagnetic or antiferromagnetic order. Transitions between these two forms of magnetic order can be induced through variations in non-equilibrium driving, lattice geometry and Coriolis forces mimicking an external magnetic field. Our experimental results agree with theoretical predictions from a generalized Kuramoto model, establishing HSLs as a generic paradigm for active phase oscillator dynamics with complex particle-wave coupling.

*NSF CMMI-1727565

12:03PM G15.00003: Emergence of multi-vortex states in swarms of active magnetic rollers* KOOHEE HAN (Presenter), Materials Science Division, Argonne National Laboratory, GAŠPER KOKOT, Northwestern Argonne Institute of Science and Engineering, ANDREAS GLATZ, ALEXEY SNEZHKO, Materials Science Division, Argonne National Laboratory — Active matter represents an emergent class of out-of-equilibrium dissipative systems demonstrating complex self-organization, collective behavior, and tunable functionalities. In both artificial and biological active systems, the vortex phase is of great interest because of its spontaneous emergence from a translational motion of elementary units and its ability to maintain the emergent dynamic structures. However, the generation of long-lived multi-vortex states without geometrical confinement has been challenging. We report that flocking magnetic rollers driven by a vertical a.c. magnetic field [1,2] can form long-lived multi-vortex states in an unconfined environment. We reveal that the absence of confining boundaries allows the emergence of multiple vortices with a wide distribution of vortex size and angular speed. In addition, these vortices exhibit equal probability distribution of clockwise or counterclockwise rotation with characteristic opposite chiralities of nearest neighboring vortices.

*The research was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Materials Sciences and Engineering Division.
12:15PM G15.00004: Controlled Self-Assembly of Vortex in Ensembles of Active Magnetic Rollers*  
ANDREY SOKOLOV (Presenter), GAŠPER KOKOT, ALEXEY SNEZHKO, Argonne National Laboratory — Magnetically driven colloids, an example of active matter, are able to demonstrate complex collective behavior and self-organize into coherent dynamic patterns via short- and long-range interactions. Here we present a method for guided self-assembly of ferromagnetic rolling particles energized by a uniform AC magnetic field into a stationary vortex via magnetic interaction with an additional strongly localized magnetic field. By tuning the parameters of the additional field we effectively control vortex dimensions, internal order, and a number of entrapped rollers. We find that vortex self-organization is assisted by field-induced magnetic steering and controlled by a phase shift between alternating magnetic fields. The presented method for assisted self-organization of rolling colloids into a vortex with on-demand characteristics suggests a new paradigm for active matter control and may lead to the development of new approaches for microscopic transport in active particles systems.

12:27PM G15.00005: Self-phoretic helical colloids  
WILLIAM USPAL (Presenter), RUBEN POEHNL, Mechanical Engineering, University of Hawai‘i at Manoa — Chemically active colloids self-propel by catalyzing the decomposition of molecular "fuel" available in the surrounding solution. If the various molecular species involved in the reaction have distinct interactions with the colloid surface, and if the colloid has some intrinsic asymmetry in its surface chemistry or geometry, there will be phoretic flows in an interfacial layer surrounding the particle, leading to directed motion. Most studies of chemically active colloids have focused on spherical, axisymmetric “Janus” particles, which (in the bulk, and in absence of fluctuations) simply move in a straight line. For particles with complex (non-spherical and non-axisymmetric) geometry, the dynamics can be much richer. Here, we consider chemically active helices and helix-sphere dimers. Via numerical calculations and slender body theory, we study how the translational and rotational velocities of the particle depend on geometry and the distribution of catalytic activity over the particle surface. Significantly, we find that both tangential and circumferential concentration gradients contribute to the particle velocity, and that the relative importance of these effects, which can be tuned by varying the particle geometry, determines the topology of the surrounding flow field.
Microorganisms exhibit autonomous locomotion through complex media and can react to changes in their environment. *Leptospira* bacteria, for example, swim towards regions of high viscosity [1]. This ability of bacteria and living cells to adapt their motion in response to external stimuli is called taxis [2]. While different kinds of taxis have been studied, most notably chemotaxis, the mechanism behind viscotaxis was not investigated until recently. Liebchen et al. found that swimmers with nonuniaxial body shapes swim up viscosity gradients due to the generation of asymmetric viscous torques acting on different parts of the swimmer [3]. We are testing these theoretical predictions using artificial microswimmers created by 3D printing based on two-photon lithography that gives us access to virtually any shape. We have started with the fabrication of trimers on the micrometre scale, the simplest form of a nonuniaxial body shape, but we are also exploring the motion of other nonuniaxial swimmers such as starships.

To develop active nanomaterials that can instantly respond to external stimuli with designed mechanical motions is an important step towards the realization of nanorobots. Herein, we present our finding of a versatile working mechanism that allows instantaneous change of alignment direction and speed of semiconductor nanowires in an external electric field with simple visible-light exposure. The light induced alignment switch can be cycled over hundreds of times and programmed to express words in Morse code. With theoretical analysis and simulation, the working principle can be attributed to the optically tuned real-part (in-phase) electrical polarization of a semiconductor nanowire in aqueous suspension. The manipulation principle is exploited to create a new type of microscale stepper motor that can readily switch between in-phase and out-phase modes, and agilely operate independent of neighboring motors with patterned light. This work could inspire the development of new types of micro/nanomachines with individual and reconfigurable maneuverability for many applications.

*We are grateful for the support of NSF via the CAREER Award (grant no. CMMI 1150767 and intern supplement) and research grant (EECS-1710922) and Welch Foundation (grant no. F-1734).
1:03PM G15.00008: Bulk Viscosity of Dilute Gases using Nonequilibrium Molecular Dynamics Simulations  BHANUDAY SHARMA (Presenter), RAKESH KUMAR, Department of Aerospace Engineering, Indian Institute of Technology Kanpur, India — Recent studies have reported that bulk viscosity, $\mu_b$, may play an important role in several fluid mechanical phenomena including fluid instabilities, turbulence, and hypersonic flows. However, accurate estimation of $\mu_b$ is a challenging task and relies on indirect techniques like acoustic spectroscopy, Rayleigh-Brillouin scattering, and Green-Kubo method. These techniques have several limitations. In the present work, a new method is proposed for the estimation of the bulk viscosity of dilute gases using nonequilibrium molecular dynamics simulations. In this method, the fluid is expanded or compressed with a known expansion/compression rate ($\nabla \cdot v$), where $v$ is the velocity of the fluid. During this volume change process, mechanical ($p_{\text{mech}}$) and thermodynamic pressures ($p_{\text{thermo}}$) are estimated using instantaneous translational and total kinetic energy, respectively. The $\mu_b$ is then obtained by the relation: $\mu_b = (p_{\text{thermo}} - p_{\text{mech}}) / \nabla \cdot v$. The proposed method is applied to estimate the $\mu_b$ of dilute nitrogen gas. The results are compared with available experimental data and a good agreement is observed. Effects of temperature, pressure, rate and direction (i.e., expansion or compression) of volume change, and humidity on $\mu_b$ are reported. (Sharma, B., & Kumar, R., Phys. Rev. E 100, 013309)

Session G16 DQI: DQI Invited Session: Experimental Advances in Quantum Sensors and Sensing 201 - Kater Murch, Washington University, St. Louis - Tag(s): Invited, Undergrad Friendly

11:15AM G16.00001: Quantum metrology methods for dark matter searches* [Invited]  KONRAD LEHNERT (Presenter), JILA and Physics, University of Colorado, Boulder — Can emerging quantum technologies speed up the search for dark matter? For the case of ultralight dark matter particles with rest mass energies of an meV or less, they can. In particular, laboratory searches for such hypothetical particles attempt to sense a persistent, oscillatory, and classical dark matter signal acting on a quantum harmonic oscillator. Not only can emerging quantum technologies measure the oscillator's motion at the quantum limit, but they can also circumvent that quantum noise in an inference of the classical signal. I will describe the particular case of axionic dark matter, in which superconducting quantum circuits can be used to search for dark matter at a rate exceeding the quantum-limited value.

1:03PM G16.00004: Morgan W Mitchell Invited Talk [Invited] —
11:15AM G17.00001: RuleSet-based Operation of the Quantum Internet* [Invited] RODNEY VAN METER (Presenter), Keio Univ — The challenges in building a Quantum Internet extend far beyond having a physical layer that can create entanglement across a distance. Quantum Internet nodes must share management of distributed tomography, errors, entanglement swapping, multiplexing of resources, selection of routes, and more to support application-requested actions for distributed cryptographic functions, quantum sensor networks, and distributed quantum computation. RuleSet-based operation allows for single-point but any-location decisions on policy for a connection and distributed, real-time selection of actions consistent with those policies. Only such an architecture will provide the full flexibility needed to support inter-technology, inter-organizational communications on a long-lived, multi-generational Quantum Internet.

*This material is based upon work supported by the Air Force Office of Scientific Research under award number FA2386-19-1-4038.

11:51AM G17.00002: Resource-efficient quantum communication using all-photonic graph states generated from quantum emitters* PAUL HILAIRE (Presenter), EDWIN BARNES, SOPHIA ECONOMOU, Virginia Tech — The emergence of quantum communication technologies shows great promise for applications ranging from the secure transmission of secret messages to distributed quantum computing. Due to fiber losses, long-distance quantum communication requires the use of quantum repeaters, for which there exist quantum memory-based schemes and all photonic schemes. While all-photonic approaches based on graph states generated from linear optics avoid coherence time issues associated with memories, they outperform repeaterless protocols only at the expense of a significant overhead in resources. Here, we consider using quantum emitters to produce the graph states and show how the resource/performance trade-off can be optimized to yield a protocol that outperforms both repeaterless and memory-based schemes. Our results should pave the way towards the practical implementation of both resource-efficient and fast long-distance quantum communication.

*This research was supported by NSF (GrantNo. 1741656).
12:03PM G17.00003: Stable Polarization Entanglement based Quantum Key Distribution over Metropolitan Fibre network* YICHENG SHI (Presenter), MOE THAR SOE, HOU SHUN POH, JAMES ANTHONY GRIEVE, CHRISTIAN KURTSIEFER, ALEXANDER LING, Centre for Quantum Technologies, National University of Singapore — We demonstrate a Quantum key distribution (QKD) system implemented with polarisation-entangled photons over telecom fibre network. The photon pairs are generated at telecom O-band with one side propagating through 10 km of deployed fibre. Drift of polarisation state over fibre is compensated using liquid crystal variable retarders to minimize the Quantum Bit Error Rate (QBER). This ensures stable, continuous QKD operation with an average QBER of 6.4% and a final key rate of 109 bits/s.

*This research is supported by the National Research Foundation, Prime Ministers Office, Singapore under its Corporate Laboratory@University Scheme, National University of Singapore, and Singapore Telecommunications Ltd.

12:15PM G17.00004: Experimental Study of an Elementary Cryogenic Microwave Quantum Network* PAUL MAGNARD, PHILIPP KURPIERS, JANIS LÜTOLF, FABIAN MARXER, SIMON STORZ (Presenter), JOSUA SCHÄR, ANDREAS WALLRAFF, ETH Zurich — Scaling up quantum computers can follow two routes in parallel: increasing the computing power of single processors, and connecting multiple processors into quantum networks using chip-to-chip deterministic quantum protocols. In both cases, modularity is a key concept. Similarly, the space available at cryogenic temperatures and cooling power needed for superconducting quantum processors can be scaled-up in a modular way by connecting dilution refrigerators into cryogenic networks. In this talk, we present an experimental study of essential elements of a cryogenic quantum network. Based on a modular design, we realize a proof-of-concept, cryogenic link between two network nodes. We thoroughly analyze the thermal properties of the link elements and extrapolate to distance scales which appear attainable in the presented approach. We also report progress toward transferring quantum information between nodes of the network.

12:27PM G17.00005: Rapid transfer of a qubit state into a microwave pulse using a notch Purcell filter*  
YOSHIKI SUNADA (Presenter), The University of Tokyo, SHINGO KONO, RIKEN, JESPER ILVES, SHUHEI TAMATE, YUTAKA TABUCHI, YASUNOBU NAKAMURA, The University of Tokyo — Modules in a distributed quantum computer need to communicate rapidly and coherently with each other. A recent implementation [1] involves transferring the quantum state between a superconducting qubit and an itinerant microwave pulse. To realize high-speed communication with this scheme, the qubit has to be coupled to a waveguide via a low-Q resonator. However, this increases the energy decay rate of the qubit through the Purcell effect. To break this trade-off, a Purcell filter with a high extinction ratio is required. Here, we use a notch filter to demonstrate the rapid transfer of a qubit state into a microwave pulse. The Purcell decay is suppressed by the destructive interference between multiple decay paths through a multi-mode resonator. This is realized in a simple device with one port and one coaxial transmission line resonator [2]. We report our progress on analyzing the filter performance and the fidelity of the state transfer.

12:39PM G17.00006: A genuine quantum router for microwave photons  
ZHILING WANG (Presenter), ZENGHUI BAO, YUKAI WU, HONGYI ZHANG, YIPU SONG, LUMING DUAN, Tsinghua University — A quantum router uses a control qubit to direct the signal qubit to a certain address, which could take a quantum superposition depending on the quantum state of the control qubit. As the elementary building block of a quantum network and a quantum random access memory, the development of a quantum router may accelerate many research fields like quantum entanglement distribution and quantum machine learning. In recent years, many attempts have been made to realize a quantum router in the optical domain. In this talk, I will introduce our experiments of realizing a genuine quantum router in the microwave domain based on superconducting circuit quantum electrodynamics system and demonstrate the coherent routing of a microwave quantum state with high fidelity using a transmon qubit.
12:51PM G17.00007: Quantum communication networks with superconducting qubits*
YOUPENG ZHONG (Presenter), AUDREY BIENFAIT, HUNG-SHEN CHANG, MING-HAN CHOU, CHRISTOPHER R CONNER, University of Chicago, ETIENNE DUMUR, Argonne National Laboratory; University of Chicago, JOEL GREBEL, RHYS G POVEY, DAVID I SCHUSTER, University of Chicago, ANDREW CLELAND, Argonne National Laboratory; University of Chicago — Deterministic state transfer and remote entanglement with microwave photons has recently been demonstrated using different superconducting circuit approaches. More recently, a qubit-to-qubit transfer fidelity greater than 94% has been achieved in Ref. [1]. This experiment used gmon tunable couplers to control the coupling of the qubits to a 0.78 m long transmission line, achieving few nanosecond tuning speed and large tuning range, thereby allowing for the violation of Bell's inequality in a superconducting quantum communication architecture. In this talk, we examine the scalability of this architecture, and explore more complex quantum communication network designs and protocols.

1:03PM G17.00008: Unidirectional emitter and receiver of an itinerant microwave photon in an open waveguide*
NICOLAS GHEERAERT, RCAST, The University of Tokyo, SHINGO KONO (Presenter), CEMS, RIKEN, YASUNOBU NAKAMURA, RCAST, The University of Tokyo — Quantum networks based on itinerant microwave photons can be an alternative approach toward a large-scale superconducting quantum computing. Recently, there have been several implementations of quantum state transfer between two localized superconducting qubits. Toward more complex networking, the control of the propagation direction of itinerant photons, such as routing, switching or circulating, is demanded. Here, we theoretically demonstrate unidirectional emission and absorption of an itinerant microwave photon in an open waveguide using a unit consisting of two superconducting qubits that are parametrically coupled to the waveguide via transfer resonators a quarter-wavelength apart. Upon preparing an appropriate entangled state of the two qubits, a photon is then unidirectionally and deterministically emitted to the open waveguide, as a result of the destructive interference — on the right or left of the device — of the radiation emitted from each qubit in both directions. We also show that this two-qubit system is able to deterministically receive a photon arriving from either direction of the waveguide, which cannot be realized with a single qubit.

*This work is partly supported by JSPS KAKENHI (18F18799), JST ERATO (JPMJER1601), and MEXT Q-LEAP (JPMXS0118068682).
Modular networks present a compelling approach to constructing complex quantum machines, but rapid and faithful communication between modules remains a challenge. Reliance on lossy elements such as circulators, hybrids, and connectors have prevented previous demonstrations from taking advantage of the high intrinsic quality of superconducting transmission line links between modules. Here we present an all-superconducting demountable coaxial link which supports low-loss standing-wave modes. We use one of these modes as a quantum bus, coupling two 3D cavity bosonic qubits in separate modules with parametric conversion, and construct a beamsplitter-type transformation between the two cavity modes. This talk will discuss how this flexible operation can be used for bidirectional state transfer and entanglement generation between modules.

*The U.S. Army Research Office (ARO) grant number W911NF-18-1-0212
The U.S. Army Research Office (ARO) – MURI grant number W911NF-16-10349

We use a quantum bus to transfer qubits and generate entanglement across a two-node network. Crucially, both of these operations can be made less sensitive to loss in the bus by encoding information with multiple photons and detecting loss errors. We transfer a bosonic qubit, tracking loss events to preserve the quantum information, achieving an error rate as low as that in a single-photon encoding. Further, we generate entanglement with two-photon interference and postselect against errors with local parity measurements, producing a Bell state with a high success probability and half the error of single photon case. These results provide several approaches for high-fidelity gates in a quantum network.

Josephson-Photonics Devices as a Source of Entangled Microwave Photons

SIMON DAMBACH (Presenter), School of Physics and Astronomy, University of Nottingham, AMBROISE PEUGEOT, SPEC (UMR 3680 CEA-CNRS), CEA Paris-Saclay, JUHA LEPPÄKANGAS, Physikalisches Institut, Karlsruhe Institute of Technology, BJÖRN KUBALA, Institute for Complex Quantum Systems, Ulm University, MARC WESTIG, GERBOLD MÉNARD, YURI MUKHARSKY, CARLES ALTIMIRAS, PATRICE ROCHE, PHILIPPE JOYEZ, DENIS VION, DANIEL ESTEVE, FABIEN PORTIER, SPEC (UMR 3680 CEA-CNRS), CEA Paris-Saclay, JOACHIM ANKERHOLD, Institute for Complex Quantum Systems, Ulm University — The realization and characterization of efficient sources of entangled microwave photons is of paramount importance for many future applications of quantum technology. Josephson-photonics devices are very promising candidates for this task since they allow one to create a broad range of different entangled states in a surprisingly simple and robust way. These devices consist of a dc-voltage–biased Josephson junction which is placed in series to several microwave cavities. Steady states with multifaceted entanglement properties are reached here naturally due to the interplay of multiphoton creation processes by the Josephson current and subsequent individual photon leakage from the cavities. In this talk, we present a detailed theoretical study of the bipartite entanglement between photon pairs in the output transmission lines. Numerical simulations, taking into account low-frequency fluctuations of the bias voltage and the finite bandwidth of microwave signal detectors, show excellent agreement with recent experimental data.

**1:51PM G17.00012: Superconducting Qubits for Robust Remote Entanglement via Adiabatic State Transfer**

HUNG-SHEN CHANG (Presenter), YOUPENG ZHONG, AUDREY BIENFAIT, MING-HAN CHOU, CHRISTOPHER R CONNER, University of Chicago; ETIENNE DUMUR, University of Chicago; Argonne National Laboratory, JOEL GREBEL, University of Chicago, GREGORY PEAIRS, University of California, Santa Barbara; University of Chicago, RHYS G POVEY, University of Chicago, KEVIN SATZINGER, University of California, Santa Barbara; University of Chicago, ANDREW CLELAND, University of Chicago; Argonne National Laboratory — Efficient quantum communication between remote quantum nodes relies on high fidelity quantum state transfer and entanglement generation. Loss in the communication channel connecting the quantum nodes can significantly limit the efficiency of these processes. One proposed method to overcome channel loss is to use adiabatic protocols to transfer quantum states without populating the lossy communication channel. Here we construct and operate a superconducting system to test such methods, using two superconducting qubits connected by a 0.73 m long transmission channel, where the channel loss can be externally varied over two orders of magnitude (as measured by the Q of the resonant channel modes). We demonstrate that in the limit of low loss, an adiabatic passage method performs as well as previously demonstrated relay method [1], while in the presence of strong loss, the adiabatic passage achieves states transfer and entanglement fidelities more than a factor of two larger than the relay method.

**Session G18 GSNP: Quantum Biology: Beyond Photosynthesis** 205 - Clarice Aiello, University of California, Los Angeles - Tag(s): Invited
11:15AM G18.00001: Quantum Biology: From Theoretical Principles to Methods of Verification* [Invited] MARTIN PLENIO (Presenter), Institute of Theoretical Physic and Center for QuantumBioSciences, Ulm University — With the improvement of experimental technique, recent years has seen the emergence of the field of quantum biology that unfolds at the interface of the quantum and the life sciences. This field examines several broad lines of development. First, it aims to explore the possible role of quantum dynamics in fundamental processes of life and has led theory to the discovery of a range of underlying principles that may support such processes, notably, the highly non-trivial interplay of quantum coherence and environmental noise. Secondly, the need for experimental verification of such phenomena provides new impetus to the development of quantum technologies that enable the observation of biological phenomena in hitherto unachieved detail making use for example of ultrafast laser spectroscopy but potentially also quantum sensors such as the NV-center in diamond. Thirdly, biological systems themselves may enable the realisation of new sensor functionalities that make use of the newly discovered theoretical principles such as the interplay of quantum coherent dynamics and noise. In this talk I will present key aspects of these three lines of development.

*This work was supported by the European Research Council Synergy grant BioQ (Grant No. 319130), the EU H2020 Quantum TechnologyFlagship project ASTERIQS (Grant No. 820394), the EUH2020 Project Hyperdiamond (Grant No. 667192) and the BMBF via NanoSpin and DiaPol.

11:51AM G18.00002: New horizons in quantum biology: Plasmon, exciton, and phonon correlations in complex biomolecular systems [Invited] PHILIP KURIAN (Presenter), Howard University — The emergence of supramolecular complexes, biological polymers, and hybrid quantum information processing assemblies from fundamental constituents and interactions involves a delicate interplay between forces of disorder (chaos) and order (logos). Quantum behaviors including electron dispersion, superradiance, and optical-to-phonon transduction have risen to the surface of our nano-, meso-, and macro-scopic perception within the open systems of biology. Extended, many-body van der Waals effects are implicated in the uncanny ability of certain enzymes to synchronize catalysis, and ultraviolet photoexcitations in large (L >> λ), highly symmetrical aggregates reveal collective, cooperative, and coherent properties that are within observational reach (few-picosecond) of ultrafast spectroscopy experiments. Intriguingly, the aqueous environment--matrix of life--challenges purely Brownian descriptions and conspires with biomatter in the precise spatiotemporal orchestration of diverse processes within the living organism. The tantalizing possibility that such ubiquitous quantum phenomena in biology can be exploited in vivo would herald a new era for diagnostic and therapeutic applications in medicine, particularly in complex neurodegenerative diseases without clear biochemical targets.
The electron's spin and chirality, the source for quantum effects in biology* [Invited] RON NAAMAN (Presenter), Weizmann Institute of Science — While the charge of the electron is known to play a major role in biological processes, and charge transfer was investigated extensively, it is usually assumed that the electron's spin does not play any important role. We found that chiral organic molecules can act as spin filters in electron transfer. The new effect, termed Chiral Induced Spin Selectivity (CISS), was found, among others, in biomolecules and in bio-systems.

In nature, very important molecules like proteins and sugars, are chiral. Chiral molecules lack mirror symmetry and they appear in two forms, enantiomers, that are not imposable on each other. Interestingly, all chiral molecules in nature appear basically in one enantiomeric form, while the other form is missing.

The issue of the origin of homo chirality in nature is under extensive debate. Independent on its origin, the question is “why evolution preserves chirality?” Another related question is why electron transfer in Biology occurs through proteins, that are bad conductors, and not through conjugated molecules for example. In other word, an important question is if the chirality in biomolecule serves specific functions that cannot be fulfilled with achiral molecules.

Based on the CISS effect, it will be shown that indeed chirality is essential for many functions in biology and this “topological” property is used by nature at physiological relevant temperatures.

Proton and electron tunneling effects in enzymes [Invited] ADAM OFFENBACHER (Presenter), East Carolina University — Accumulating evidence supports the quantum mechanical treatment of both electron and proton transfer associated with homolytic C-H bond cleavage reactions catalyzed by natural enzymes. These reactions are quantified and characterized by inflated kinetic isotope effects corresponding to the primary bond cleaved and the corresponding differential enthalpic barrier for the transfer of hydrogen and its heavy isotopes. Herein, select examples will be presented that demonstrate the quantum behavior in enzyme catalysis and highlight how these kinetic tools can be applied to resolve the origins of enzyme reactions.
Quantum-Based magnetic sensing: How can birds detect 10 nT magnetic fields? [Invited] THORSTEN RITZ (Presenter), University of California, Irvine — Migratory birds and other animals can navigate thousands of miles to find their destinations. In this they are aided by a “sixth sense”, i.e. the ability to detect the geomagnetic field. Growing evidence indicates that the threshold of the biological magnetic sensor is on the order of 10 nT. This poses a major challenge for physicists since no mechanism can currently explain how such sensitivity can be realized in a concrete biomolecular system. Light-induced radical-pair reactions can be sensitive to earth-strength magnetic fields and thus may form the basis for the long-sought after magnetic sensors. If this hypothesis was proven, it would be a dramatic demonstration of the use of coherent quantum mechanics to establish biological functionality. We will review the current theoretical questions regarding this mechanism, such as how to design a particularly sensitive receptor system, the role of noise, symmetries and dealing with decoherence before turning to experimental evidence for this hypothesis. We will present a roadmap of key steps that will ultimately enable us to prove or disprove the now nearly twenty year old suggestion that cryptochromes may be the magnetoreceptor molecule and the even older suggestion of a radical-pair mechanism underlying magnetic sensing.

Tuesday, March 3, 2020 11:15 AM - 2:15 PM

Session G19 DPOLY: Revealing the Microscopic Dynamics Driving Nonlinear Polymer Flows

11:15AM G19.00001: Self-Healing Recovery and Dynamics of Associating Polymers under Uniaxial Extension [Invited] NICOLAS ALVAREZ (Presenter), ZACHARY R HINTON, Drexel Univ — Associating polymers are a desirable class of materials with intrinsic abilities to self-heal without the need for additional components or added stimulus. While experimental and theoretical measurements of recovery exist in the literature, quantifying recovery in terms of fundamental rheological parameters is often difficult. In this work we use filament stretching uniaxial extension to probe the recovery of unentangled and entangled hydrogen bonding polymers. Using a novel methodology, we confirm the role of process timescales such as the time before and after recovery on both the transient rheology and ultimate recovery of associating polymers. Furthermore, we show the importance of architecture and molecular timescales of the network on recovery. We find that while strongly associating groups provide improved mechanical strength, they often delay the process of recovery. Additionally, we show that the presence of entanglements has a complex role on recovery, introducing the flow timescale as an additional parameter. With this work, we develop a framework that is both useful for evaluation of self-healing soft materials and for design of novel self-healing polymers.
11:51AM G19.00002: Decoding the viscoelastic response of monodisperse and bidisperse linear polymers under uniaxial extension [Invited]  EVELYN VAN RUYNBEKE (Presenter), CELINE HANNECART, ALEXIS ANDRE, TAISSIR SHAHID, Bio and Soft Matter, IMCN, Université catholique de Louvain — Predicting the linear viscoelastic properties of linear polymers has reached a quantitative level, based on mesoscopic approaches such as slip-link models or the Doi-Edwards tube-model theory combined with established relaxation mechanisms such as reptation, contour length fluctuations and constraint release. A consistent molecular picture could be proposed for describing the linear regime, which allows explaining the different experimental data based on the same framework. In particular, in case of polymer chains diluted in an oligomer matrix, the universality of linear viscoelastic response of polymers has been demonstrated with different chemical structures and concentrations: as long as the chains contain the same number of entanglements, their normalized viscoelastic properties will be the same.

On the contrary, it was shown recently that the universality between polymer melts and solutions breaks down under nonlinear elongational flows: while polymer melts exhibit a monotonic extension-thinning behavior for all applied strain rates, polymer solutions with the same number of entanglements exhibit an initial thinning behavior followed by a strong extension-hardening, which occurs at rates comparable to the reciprocal Rouse time of the chains. As a result, molecular theories for linear flows cannot be extended to nonlinear flows without further considerations.

In the present work, we explore the elongation properties of systematic sets of polymer blends and oligomer solutions in order to understand the molecular origin of this non-universality and the absence of extension thickening for polymer melts. This allows us to show the importance of analyzing separately flow-induced and time-induced relaxation processes in order to reunify the behavior of polymer melts and solutions. We then show how these mechanisms can be taken into account in tube-based models, towards a general picture to describe the viscoelastic properties of entangled polymers under elongation flow.

12:27PM G19.00003: Evidence of Flow-Induced Crystallization in Material Extrusion Additive Manufacturing [Invited]  ANTHONY KOTULA (Presenter), National Institute of Standards and Technology — Material extrusion additive manufacturing processes force molten polymer through a printer nozzle at high (>100 s⁻¹) shear rates prior to cooling and crystallization. This can lead to flow-induced crystallization in common polymer processing techniques, but the magnitude of this effect is unknown for additive manufacturing. Here, we will show the effect of the material extrusion on the morphology of poly(lactic acid), a common semicrystalline polymer used in material extrusion. The talk will encompass materials characterization (rheology and crystallization kinetics) relevant to printing, process line temperature measurements, and polarized optical microscopy techniques to characterize the final microstructure, which we compare with continuum modeling. Although no crystalline domains are seen in the as-printed part, a post-print annealing process reveals spherulitic domains with sizes that dramatically decrease near the weld line. Our results show that residual chain stretch from the extrusion and deposition process enhances the nucleation rate in the weld regions between extruded layers. The higher nucleation density in these regions is not obvious in the as-printed part but is revealed only through the annealing process, which is captured in the model.
Many industrial processes elongate polymer liquids at rates much faster than the molecular chain's characteristic relaxation times. These nonlinear extensional flows can strongly deform microscopic polymer conformations and drive dynamic transitions that produce large changes in polymer viscosity. Understanding how flow depends upon and drives such changes in polymer microstructure is essential for improving established and emerging fabrication methods like fiber spinning and 3D printing. However, most microscopic understanding of these nonlinear flows has been drawn from indirect techniques that infer molecular dynamics from macroscopic rheology. This has begun to change with the recent development of new experimental and numerical simulation techniques that allow researchers to control, sustain, and microscopically probe polymer dynamics during strong extension. Here, I’ll present molecular simulations for linear, star, and ring polymer melts and blends deformed in uniaxial extensional flow. In all three cases, coarse-grained molecular dynamics simulations reproduce the nonlinear rheology observed in extensional flow experiments, and also reveal the microscopic dynamics driving observed nonlinear trends. For some architectures, simple theoretical arguments can directly relate the elongated conformations of molecules to the nonlinear viscosity. In other cases, simulations show how extensional flows can drive polymers to topologically self-assemble or micro-phase separate in ways not seen in equilibrium. These new, far from equilibrium behaviors could provide new routes for controlling polymer microstructure during processing.

Polymer Scission in Contraction Flows* [Invited]  
PETER OLMSTED (Presenter), Georgetown University, SANDEEP GARREPALLY, FRANCOIS LEQUEUX, ESPCI, STEPHANE JOUENNE, Total SA — Polymer scission has been studied for many years! It has numerous practical implications in areas such as drug injection, spraying and printing, and oilfield harvesting. When injected through a contraction flow, high molecular weight polymer solutions exhibit a sharp increase of apparent viscosity due to chain stretching during fluid extension. This stretching can induce polymer scission, which then decreases the extensional viscosity. We revisit this old problem using specially-designed microfluidic hyperbolic contraction flows. We study the pressure-flux relation for high molecular weight polymer solutions passing through the contraction, and find that the ratio of the pressure drop to that of the (Newtonian) solvent has a maximum due to the competition between polymer extension and degradation (scission). From the dependence of the pressure maximum on flow rate and molecular weights we can quantify the decrease in equivalent molecular weight due scission in the contraction. We find a geometry-dependent quasi-universal relation between the flow rates at which the maximum occurs for successive passage in a given contraction, which appears to be independent of molecular weight, concentration, solvent quality and viscosity, and can be used to predict degradation under successive passes. I will discuss what we can learn about the the details of the scission kinetics in flow from these observations.

*Funding provide by Total, ESPCI, and Georgetown University (Joseph Semmes Ives endowment).

Tuesday, March 3, 2020 11:15 AM - 2:15 PM

Session G20 GDS: Data Science II: Machine Learning 301 - Brian Barnes, US Army
Rsch Lab - Aberdeen
11:15AM G20.00001: Addressing the Elephant in the Room: Uncertainties in Physical Predictions From Machine-Learned Force Fields  STEFAN CHMIELA (Presenter), HUZIEL SAUCEDA, KLAUS-ROBERT MÜLLER, Tech Univ Berlin, ALEXANDRE TKATCHENKO, University of Luxembourg — Learning molecular force-fields (FF) has played a leading role in the path towards reliable molecular dynamics simulations in biology, chemistry, and materials science[1,2]. However, simulation's predictive power is only as good as the underlying interatomic potential. Although it is common practice to evaluate the reliability of trained FF models based on typical error measures, this only quantifies the error on the database given a set of training points. The relevant question to ask is how well a learned FF reproduce the actual physical properties a system. Here, we present an analysis of the uncertainties in properties derived from learned-FFs, such as vibrational spectrum and thermodynamics. A clear correlation is found between learning errors and the derived properties' uncertainty. The robustness of the symmetric gradient-domain machine learning (sGDML) framework[1] against such problem is evinced by its fast uncertainty minimization with the training set size. These results will serve as reference for the developing of robust and predictive learned physical models.

11:27AM G20.00002: Understanding key challenges in digitizing and contextualizing experimental results  HA-KYUNG KWON (Presenter), CHIRRANJEEVI GOPAL, BRIAN D STOREY, Toyota Research Institute, SANTIAGO CAICEDO, JARED KIRSCHNER, EPAM-Continuum — Recent advances in automated, high-throughput experimentation have enabled scientists to leverage machine learning methods and structured data in screening large parameter spaces. These approaches could be even more effective if supplemented by data collected in traditional experimental labs, where samples are handed off between collaborators at multiple processing and characterization steps. In these settings, unstructured experimental observations recorded in physical lab notebooks can provide context for data and metadata collected from a variety of instruments. Despite a number of electronic lab notebook products available in market, digitization of experimental notes remains a challenge due to low levels of adoption by researchers. In this talk, we present our findings from user research conducted in three different academic labs, on researchers' behaviors and needs throughout the experimental process. We discuss methods based on human-centered design to guide the development of an easily adoptable solution that seeks to 1) integrate experimental notes into data-driven software platforms, 2) contextualize experimental data obtained from multiple sources, and 3) enhance knowledge transfer between collaborators, thereby accelerating scientific discovery in experimental labs.
11:39AM G20.00003: Using Machine Learning to Reduce Low-Q Disorder in Quasiparticle Interference Maps*  
AIDAN WITECK (Presenter), YU LIU, JENNIFER E. HOFFMAN, Physics, Harvard University — Scanning tunneling microscopy (STM) is a commonly used technique to examine a material on the atomic scale. Quasiparticle interference (QPI) extends its ability to resolve the band structure of materials in the reciprocal space by imaging the scattering patterns of impurities in the real space. Those scattering patterns are normally analyzed with the Fourier transform. However, the Fourier transform suffers from low-q noise arising from correlations between impurity centers, drastically decreasing band resolution in low-q regions. Here we present a novel algorithm that uses Fourier filtering and machine learning to reduce low-q noise. We validate this method using both simulated QPI data and real QPI data from various materials. Our method reduces low-q disorder without the introduction of artifacts, allowing us to more clearly examine the low-q band structure.

11:51AM G20.00004: CdTe nanoparticles as temperature sensors via machine learning of optical properties  
JOHN COLTON (Presenter), JAMES W ERIKSON, CHARLES LEWIS, CARRIE E MCCLURE, DEREK SANCHEZ, TROY MUNRO, Brigham Young Univ - Provo — We have investigated using CdTe nanoparticles as non-invasive temperature sensors. Optical photoluminescence (PL) spectra and time-resolved photoluminescence (TRPL) were measured as functions of temperature and used as inputs to an artificial neural network (ANN) for purposes of machine learning. Two regimes were studied: low temperature, data taken from 10-320 K in steps of 10 K; and high temperature, data taken from 325-346 K in steps of 1 K. Five data sets were withheld for validation from the low temperature data; four from the high temperature. We used preprocessing techniques of min-max normalization and (for the low temperature regime) interpolation to generate additional training samples. Best results for both regimes were obtained using a seven layer fully connected ANN architecture. Hyperparameters varied to optimize the network include number and size of layers (including convolutional layers), batch normalization, activation functions, learning rates, and dividing the PL and TRPL data into separate input branches. Using a typical 80-20 training/testing split, the low temperature (high temperature) network was able to be trained to 0.1 K (1.0 K) training error and 0.3 K (2.5 K) testing error, which results in an error on the withheld validation data of 3.4 K (5.5 K).

NICHOLAS MARCELLA (Presenter), ANATOLY I FRENKEL, State Univ of NY - Stony Brook — The energy dependent X-ray absorption coefficient encodes the electronic and real space structure of select element species within a material. We have found that the neural network (NN) is capable of modeling this relationship in X-ray absorption near edge (XANES) and extended fine structure (EXAFS), resulting in a powerful analytic tool. To date, our NN-assisted analysis methods have been used to investigate the structure and dynamics of nanoparticles and oxide clusters as small at 4 atoms. The availability of large amounts of reliable training data, in terms of both labeling and quality, is key to an accurate NN model. For XANES and EXAFS, a database of such is not experimentally obtainable, so we must use ab initio spectroscopy codes to create a theoretical database. Because theoretical training data only approximates real observations (due to theoretical limitations, and experimental considerations such as noise, resolution, and glitching), many local minima emerge when optimizing for accurate experimental predictions. We will discuss how, by probing various local minima during training, with a set of labeled experimental data, we can find a NN which generalizes theoretical features for use in experimental predictions.

12:15PM G20.00006: Machine learning on the electron-phonon spectral function and the superconductor gap function

MING-CHIEN HSU (Presenter), WAN-JU LI, TING-KUO LEE, SHIN-MING HUANG, Physics, Natl Sun Yat Sen Univ — The phonon mediated superconductor can be described well by the Eliashberg equation. Once the electron-phonon spectral function is known either ab initially or estimated from experiments, the superconductor properties such as the gap function and the wave function renormalization can be solved self-consistently from the Eliashberg equation. However, it is important to investigate in a reverse way by inferring the possible original spectral function from known superconductor properties. The mapping can be learned by using the machine learning technique. We generate various spectral functions with numerous peaks and different shapes and solve their gap functions self consistently. With these data, the relation between each pair of the gap function and the corresponding spectral function can be learned by the machine. The functions are learned and recognized in terms of the basis function found by the neural network. The loss function will be hugely reduced each time when the neuron successfully learns a basis function. We find that in general, the neural network is very efficient to learn the correspondence between the electron-phonon spectral function with the superconductor functions mentioned.
**12:27PM G20.00007: Characteristic space of XRD patterns in machine-learning**  KEISHU UCHIMURA (Presenter), Japan Adv Inst of Sci and Tech, MASAO YANO, HIROYUKI KIMOTO, TOYOTA MOTOR CORPORATION, KENTA HONGO, Research Center for Advanced Computing Infrastructure, JAIST, RYO MAEZONO, Japan Adv Inst of Sci and Tech — X-ray diffraction (XRD) is a commonly used analytical technique to identify crystal structures. Recent advances in automatic measuring techniques enable one to obtain thousands of XRD patterns within a day. Basically, however, their analysis is done by comparing measured patterns with reference ones, which relies on experts' knowledge and great efforts. Even using a computational implement of the Rietveld refinement, characterization of some XRD patterns would take a few hours (or more) even for experts. Thus, automation/acceleration of the XRD analysis is really desired for managing high throughput XRD patterns. In this study we adopted an unsupervised machine learning technique, auto-encoder, to analyze XRD patterns. Vectorizing XRD patterns to make feature vectors, the encoder itself maps the high-dimensional vectors onto low-dimensional (say, 2-dim.) ones. It was found that XRD patterns get into groups of different compositions in the reduced feature space. We thus concluded that our scheme can capture slight difference in lattice constant caused by atomic substitutions in magnetic alloys without any prior knowledge.

**12:39PM G20.00008: Using machine learning to understand mutations***  MARTHA VILLAGRAN (Presenter), NIKOLAOS MITSAKOS, JOHN MILLER, RICARDO AZEVEDO, Univ of Houston — A single harmful base substitution in a DNA sequence can, on occasion, cause a devastating fatal disease. Determining why this happens for some mutations, but not for others, is critical to developing effective treatments and poses a central challenge to modern medicine. Mitochondrial DNA (mtDNA) is especially vulnerable, mutating about 100 times faster than the nuclear genome. Uncovering how DNA's electronic fingerprint influences its mutation spectrum is of critical importance to genetics and evolutionary biology. At the same time, machine learning, with the added capabilities of deep architectures that saw tremendous advances recently, provides a framework that allows recognizing patterns in data, even when these patterns are governed by very complex interlinked properties. We are investigating the capability of machine learning, with a focus on deep learning architectures, for detecting and predicting potential mutation locations in mtDNA. We demonstrate that these models can learn to discriminate between locations on the DNA where mutations can occur versus stable locations, to the extent that these situations are effectively represented in the available data.

*State of Texas through Texas Center for Superconductivity, University of Houston Health Research Institute and NIH.*
BRIAN BARNES (Presenter), BETSY M RICE, ANDREW E SIFAIN, CCDC Army Research Laboratory — We present advances in accurate, rapid prediction of detonation pressure, detonation velocity, heat of formation, density, and melting point of energetic molecules. Molecules evaluated are CHNO-containing organic molecules drawn from public datasets and known explosives. These models may be integrated into a larger effort for high-throughput virtual screening or rapid pre-screening of molecules before any hazardous synthesis is attempted. Our research evaluates a message-passing neural network (MPNN) model with representation learned from 2D structure trained on a large body of data generated by physics-driven (quantum mechanically derived) models, and also a thermodynamic fingerprint representation used to train a gradient-boosted decision tree method on a smaller body of experimental data. The utility of each representation and statistical model is discussed. The Python workflow for each analysis is discussed. This data-driven approach is shown to provide advances in speed and accuracy for energetic material property prediction. A brief introduction to energetic materials and detonation physics is provided for non-experts.

1:03PM G20.00010: Simulation of atmospheric turbulence with generative machine learning models  
ARTURO RODRIGUEZ (Presenter), CARLOS R CUELLAR, LUIS FERNANDO RODRIGUEZ, ARMANDO GARCIA, JOSE TERRAZAS, University of Texas, El Paso, VM KRUSHNARAO KOTTEDA, The University of Wyoming, RAO GUDIMETLA, Air Force Research Lab, VINOD KUMAR, JORGE MUNOZ, University of Texas, El Paso — The Large Eddy Simulation (LES) modeling of turbulence effects are computationally expensive even when not all scales are resolved, especially in the presence of deep turbulence effects in the atmosphere. Machine learning techniques provide a novel way to propagate the effects from inner- to outer-scale in atmospheric turbulence spectrum and to accelerate its characterization on long-distance laser propagation. We simulated the turbulent flow of atmospheric air in an idealized box with a temperature difference between the lower and upper surfaces of 10 degrees Celsius with the LES method. The volume was voxelized and several quantities such as the velocity and the pressure were obtained at regularly-spaced grid points. These values were binned and converted into symbols that were concatenated along the length of the box to create a ‘text’ that was used to train a long short-term memory (LSTM) neural network and a naïve Bayes model. LSTMs are used in speech recognition and handwriting recognition tasks and naïve Bayes is used extensively in text categorization. The trained LSTM and the naïve Bayes models were used to generate instances of turbulent-like flows.
1:15PM G20.00011: Identification of informative acoustic features in the transition from non-violent to violent crowd behavior  KATRINA PEDERSEN (Presenter), BROOKS A BUTLER, SEAN WARNICK, KENT L GEE, MARK TRANSTRUM, Brigham Young Univ - Provo — Human crowds can exhibit a variety of collective behaviors. Here, we explore the transition from peaceful to violent behavior in human crowds using acoustic data. Predicting when a crowd will transition from a peaceful to a violent state has many potential applications, such as peace-keeping and security. Relative to video, acoustic data is easier to obtain and is less affected by lighting conditions, such during night or in dark areas. We apply machine learning methods to a data set that includes both video and audio recordings of violent and non-violent crowds. Previous results showed that audio data was only marginally less effective than video alone for classifying violent/non-violent scenes. In this work, I conduct a feature-importance study to identify which acoustic metrics are most informative for correctly classifying peaceful and violent crowds.

1:27PM G20.00012: "Robust Speaker Identification System Under Adverse Conditions"  SWATI PRASAD (Presenter), Electronics and Communication Engineering, Birla Institute of Technology, Mesra, Ranchi, Jharkhand, India — When only a speech utterance is given, finding out the person who spoke the given speech utterance from a group of reference speakers is referred to as Speaker Identification. It is also known as biometric based on voice. Its success has great potential to bring a paradigm shift in the way we communicate with the machine. It will facilitate in the easier and secure communication between Man and Machine using speech. It will particularly benefit the elderly members of the society. Factors like voice disguising, emotional state of the person, background noise and throat diseases create a mismatch between the training and the test speech data, referred to as Mismatched Problem. It decreases the speaker identification accuracy and needs to be addressed. To make the speaker identification system robust against these mismatched conditions, we have developed speech frame selection methods for feature extraction. It captures the characteristics of the speech signal efficiently from the time-domain signal. For modeling the speaker, the machine learning technique, Gaussian Mixture Model with 64 components is utilized. It has shown good performance under voice disguise and environmental noise conditions. Future work will test its performance for emotional and diseased speech.
1:39PM G20.00013: Hyperbolic non-metric multidimensional scaling reveals intrinsic geometric structure in high-dimensional data  
YUANSHENG ZHOU (Presenter), University of California, San Diego, TATYANA OLEGIVNA SHARPEE, Salk Institute — Modern datasets characterize objects with respect to many variables and assign distances between objects based on a Euclidean metric. However, recent results suggest that for data produced by underlying hierarchical tree-like networks a hyperbolic metric might be more appropriate than a Euclidean one. We develop non-metric multidimensional scaling (MDS) in hyperbolic space to perform hyperbolic embedding of points. Using simulations we show that hyperbolic MDS, combined with Euclidean MDS, can be used to detect intrinsic geometry of data. Applying hyperbolic MDS to human gene expression data, we find that the samples taken from local clusters have Euclidean structure, but samples taken broadly from the whole population show hyperbolic metric, which indicates that the human gene expression space is locally Euclidean but globally hyperbolic. Further we quantify the hyperbolic radii of cells from other diverse biological systems including different mouse organs, finding that mouse brain and embryonic stem cells are also hyperbolic while organs like mouse lung, kidney and placenta are Euclidean. Our method provides a quantitative approach to detecting hidden geometric structures and quantifying cell hierarchies of diverse biological systems.

1:51PM G20.00014: Data Augmentation and Pre-training for Template-Based Retrosynthetic Prediction  
MIKE FORTUNATO (Presenter), CONNOR COLEY, Department of Chemical Engineering, Massachusetts Institute of Technology, BRIAN BARNES, Detonation Science and Modeling Branch, CCDC Army Research Laboratory, KLAVS JENSEN, Department of Chemical Engineering, Massachusetts Institute of Technology — A key step in computer-aided synthesis planning (CASP) is the prioritization of candidate molecular transformations for retrosynthetic analysis. Recent methods obtaining state-of-the-art accuracy have used machine learning (ML) models as recommendation engines to rank reaction templates extracted from databases of recorded reactions. However, data scarcity limits the ability for ML models to recommend rare, often highly desired, transformations. In this work we discuss the augmentation of open-access reaction databases with synthetically generated molecular transformations to teach neural networks generalized template applicability. We use this as a pre-training strategy, which is followed by fine tuning of the model parameters using true, recorded reactions, in order to increase the diversity of suggested retrosynthetic transformations. While previous methods have focused on learning a one-to-one-mapping from featurized molecular inputs to a single template transformation, pre-training with general template applicability allows these new models to learn a one-to-many mapping to multiple templates. The implications of performing data augmentation and pre-training on different sized datasets is discussed, as well as the changes in performance for rare reaction templates.
2:03PM G20.00015: Neural network-assisted analysis of X-ray absorption spectra of metal oxide clusters*  
YANG LIU (Presenter), NICHOLAS MARCELLA, ANATOLY I FRENKEL, Stony Brook University — It is challenging to understand the reactivity from structure perspective for the supported metal oxide clusters. Many operando characterization techniques for solving such challenge are limited due to the low-metal loading and high temperature condition. Because of the sensitivity of X-ray absorption near edge (XANES) to the local structure, we demonstrated that XANES can be analyzed and provide structural information combing with supervised machine learning method. In this work, we apply the neural network method to the analysis of grazing incidence XANES spectra of size-selective Cu oxide clusters on flat support, measured in operando condition. The convolution neural network was trained to build the correlation between the XANES and structural descriptors (Cu-Cu coordination numbers). Our result indicates that we can distinguish between different structural motifs of Cu oxide cluster during the reaction conditions and invert the experimental XANES to obtain structure parameters which helps the understanding of the structure-properties relation of the catalysts.

Session G21 GERA: Perovskites and Chalcopyrites for Energy Applications

11:15AM G21.00001: Chemical trends of absolute volume deformation potentials of all-inorganic ABX₃ halide perovskites  
SHANSHAN WANG (Presenter), MENG LIN HUANG, SHIYOU CHEN, East China Normal University — The absolute volume deformation potential (AVDP) is an important physical quantity that describes the energy level shift under pressure, which, however, has not been investigated for halide perovskites. We systematically calculate the valence band maximum (VBM) and conduction band minimum (CBM) AVDPs of all-inorganic ABX₃-type perovskites (where A = K, Rb, Cs; B = Ge, Sn, Pb; X = Cl, Br, I) in cubic structure using ab-initio calculation methods. Although it was shown that spin-orbit coupling played an important role in the band structure calculation of ABX₃ perovskite, we prove that it has negligible effect on AVDP calculation. We show that the AVDPs of VBM are all negative and large, indicating the energy level will shift down when the volume increases, while AVDPs of CBM are mostly positive and small. There are clear trends in the calculated AVDPs of both VBM and CBM which will be discussed. Our results suggest that strain is an effective way to adjust the energy level of valence band edge in ABX₃, which may be of great significance to design optoelectronic devices.
11:27AM G21.00002: Relative stability of perovskite and non-perovskite phases of inorganic trihalogeno germanates.*  WALTER LAMBRECHT (Presenter), SANTOSH KUMAR RADHA, Case Western Reserve University — One of the main problems of halide perovskites is the existence of competing non-perovskite phases. Here we focus on (Cs,Rb)GeX₃ compounds which exist either in a rhombohedrally distorted ferroelectric perovskite phase exhibiting cornersharing octahedra or a monoclinic and various orthorhombic phases with edge-sharing octahedra. We show that the GeX₃ tetrahedral building blocks are arranged antiferroelectrically (AFE) in the monoclinic phase and ferroelectrically (FE) in the perovskite phase. The electrostatic dipole interaction favors the AFE arrangement but the additional bond formation favors the perovskite. A spin model and first-principles calculations explain why the Rb based compounds prefer the monoclinic and Cs compounds prefer the perovskite form. Similar phases exist for CsSnX₃. The different structural arrangement is accompanied by a large change in band structure with a much larger gap and flat bands in the monoclinic form, which is unsuitable for photovoltaic applications. This new insight in the stability of these phases suggests the use of an electric field to control the phase transition.

11:39AM G21.00003: Contrasting GGA and hybrid functionals description of dynamic properties of CsPbI₃  ALI KACHMAR (Presenter), MARCELO CARIGNANO, QEERI, Hamad Bin Khalifa University — Caesium lead iodide perovskite exhibit similar structural properties than methylammonium (MA) lead iodide, in particular with respect to the inorganic cage. Both systems show anharmonic behavior in the halide dynamics. Having Cs instead of MA as the cation allows for a study based on expensive hybrid functionals. Considering that most of the reported first principles molecular dynamics simulations were performed using GGA functionals, it becomes pertinent to question what are the corresponding results when the forces are accounted for using the more accurate hybrid functionals. In this work we present a comparison between PBE and HSE functionals for the anharmonicity of the halide atoms at high temperature. Our study is based on first principles molecular dynamics simulations on large 444 supercells and trajectories extending up to 40 ps.
Carrier Dynamics and Recombination in Low-Dimensional Halide Perovskites: Role of Structural Fluctuations*  
DIBYAJYOTI GHOSH (Presenter), AMANDA NEUKIRCH, SERGEI TRETIAK, Los Alamos National Laboratory — Low-dimensional halide perovskites have demonstrated promising luminescence properties for light-emitting diodes due to their high radiative recombination rate.\cite{1} However, the lack of a complete understanding of the structure-property relationship hinders the systematic design of these materials to enhance their luminescence efficiency. Combining state-of-the-art nonadiabatic molecular dynamics and time-domain density functional theory, we explore the substantial effects of structural fluctuations on the excited state dynamics and carrier recombination in these perovskites. Here, I will demonstrate how structurally rigid perovskites experience weaker electron-phonon interactions, resulting in suppressed non-radiative carrier recombination and enhanced photoluminescence quantum yield (PLQY).\cite{2,3} Our work revealed that stacking of the spacer cations, and halogen composition of the inorganic layers substantially tune the PLQY of these materials. Based on these understanding, we further propose a combination of suitable spacer cations and inorganic layer compositions to improve the PLQY of low-dimensional halide perovskites.

Tailoring structural transitions in layered 2D perovskites using light  
WENBIN LI (Presenter), HAO ZHANG, Applied Physics, Rice Univ, SIRAJ SIDHIK, Chemical and Biomolecular Engineering, Rice Univ, MERCOURI KANATZIDIS, Chemistry, Northwestern Univ, JACKY EVEN, Physics, Institut national des sciences appliquées de Rennes, JEAN-CHRISTOPHE BLANCON, ADITYA MOHITE, Chemical and Biomolecular Engineering, Rice Univ — Organic-inorganic (hybrid) perovskite have recently emerged as a new semiconductor platform for next generation optoelectronics devices. These perovskite solids feature weak bonds between their organic and inorganic building blocks, which results in an intrinsic softness and dynamics disorder of the lattice and an acute sensitivity to external stimuli. For example, our group demonstrated that continuous sunlight illumination leads to a uniform expansion of the perovskite lattice, which impact the optoelectronic properties of the three-dimensional perovskites. In particular, this effect is beneficial as it helps cure electronics impurities and lowers energetic barriers near the surface/interface. Here, we present comprehensive in-situ light induced structural dynamics to layered two-dimensional (2D) hybrid perovskites. We correlate the changes in the structure of the 2D perovskite to modification of both the physical properties and the figures of merit in solar cells. We propose a new microscopic model to explain the evolution of the structure and optoelectronic properties under an external stimulus. These results demonstrate that structural characterization of hybrid perovskite under external perturbation is key in unraveling the fundamental physics of these materials.
12:15PM G21.00006: Optimization of recombination region within inorganic perovskite light emitting diodes  
LINDSEY GRAY (Presenter), XIAOHENG YAN, Wake Forest Univ, XIANG ZHANG, Jilin University, DAVID CARROLL, Wake Forest Univ — Recent advances in metal halide perovskite-based LEDs have included high brightness, extended lifetimes, and excellent color saturation in comparison with other thin film light sources such as OLEDs. We have shown that many of these properties can be traced to nanoscale sub-phase formation within the larger perovskite matrix, which leads to exciton self-trapping. However, since such phase formation modifies carrier mobility, a significant challenge in per-LEDs is optimizing device design such that the driving voltage, sensitive of recombination zone formation and position within the emitting layer, is overcome. In this work we examine the use of various organic layers, such as poly-TPD, in barrier formation and recombination zone stability. We show that interface preparation between the perovskite and transport layers can play a major role in barrier formation. Focusing on the correlation of brightness and efficiency with device structure modification, we demonstrate that optimized carrier balance can allow for maintained efficiency over a wide range of driving voltages and brightnesses.

RAMESH KUMAR (Presenter), JITENDRA KUMAR, PRIYA SRIVASTAVA, MONOJIT BAG, Indian Inst of Technology Roorkee — Owing to the exceptional optoelectronic properties, Hybrid halide perovskites (HHPs) have attracted great attention leading to the variegated application in optoelectronic devices. Study of carrier kinetics in perovskite solar cells using Impedance Spectroscopy (IS) has been the topic of research since the last few years. But, research in Perovskite LEDs (PeLEDs) is still sparse. Here, we have studied the charge carrier kinetics of PeLEDs using IS at different applied bias. The electrical equivalent circuit of the device was modelled and the variation of different parameters with applied bias was studied. We have observed the bias dependent transition of capacitance from positive to negative at low frequency. The inflection point along with the magnitude of this negative capacitance depends significantly on the morphology of the perovskite film. We have also observed anomalous capacitive behaviour for the first time at high frequency due to the interplay between electronic and ionic charge transport. We have proposed a possible model responsible for anomalous capacitive behaviour and its correlation with active layer morphology in PeLEDs.

12:39PM G21.00008: Identifying electronic descriptors to predict work functions of perovskite electrodes* YIHUANG XIONG (Presenter), WEINAN CHEN, WENBO GUO, HUA WEI, ISMAILA DABO, Pennsylvania State University — The ability to predict work functions of semiconductor electrodes is critical to the development of photocatalytic and electrocatalytic systems. Understanding the compositional and structural dependence of the interfacial electronic structure of semiconductors could enable us to screen and select appropriate functional materials for electronic applications. We address this problem with a focus on perovskite oxides (ABO$_3$) in the metastable cubic phase by enumerating the possible compositions for A- and B-site cations. We analyze the computed work functions by means of statistical learning using elemental and bulk chemical descriptors. The resulting descriptor-based model not only delivers accurate predictions of computed work functions using a limited number of features, but also allows us to interpret the complex correlations between electronic levels and surface structure across a vast chemical space.

12:51PM G21.00009: Modeling the dynamics of interacting defects, charge carriers, and excitons in perovskite solar cells BARBARA SANBORN (Presenter), Whitman College, ABDUL SHAIK, DRAGICA VASILESKA, Arizona State University — This talk presents calculations based on a theoretical model that includes the dynamics of excitons, free charge carriers, and electrically active defects, to study the stability of perovskite solar cells. Previously, the PVRD-FASP tool was developed and released for public use (www.pvrdfasp.com) to model metastability and reliability issues of solar cells. In the model, charge carriers and electrically active defect centers are treated on an equal footing, as both obey the same reaction-kinetic equations: the continuity, drift-diffusion, and the Poisson equations. The rate terms in these equations are highly non-linear and require solution of a system of stiff partial differential equations. To efficiently solve such systems, a reaction solver based on the forward Euler method implicit in time with a Newton step was proposed and implemented. The Jacobian for the Newton step was analytically calculated. The PVRD-FASP tool was used successfully to study the role of Cu migration in CdTe solar cells. In current work, the theoretical model of the tool is expanded to include the dynamics of excitons. The expanded solver is used to study the stability of perovskite solar cells in the presence of light-induced formation and annihilation of defects acting as carrier trap states.
1:03PM G21.00010: The interplay of bulk and interfacial dynamics in methylammonium lead triiodide perovskite solar cells revealed via current noise spectroscopy*  
KEVIN DAVENPORT (Presenter), MARK HAYWARD, ANDREY ROGACHEV, University of Utah — Hybrid organic-inorganic perovskite solar cells are one of the most promising emerging technologies capable of competing with silicon devices, chief among them those based on methylammonium lead triiodide (MAPbI$_3$). Fundamental understanding of electrical transport and degradation processes in these devices, however, is important for commercial realization. We have performed cross-correlated current noise spectroscopy on a series of MAPbI$_3$ devices. Under illumination, we find near-full-scale shot noise (Fano factor $F \sim 1$), indicating the dominance of a single element in the device stack. We further observe generation-recombination noise which emerges with illumination and increasing device thickness. This signal is attributed to radiative bimolecular recombination. Finally, we observe a $1/\alpha$ flicker noise ($\alpha \sim 1.4$) which deviates from the expected $I^2$ dependence. This indicates the superposition of canonical resistance fluctuations and a current and/or light-driven source, likely the migration of halide ions through the bulk.

1:15PM G21.00011: Understanding the role of Sn substitution and Pb vacancy in FAPbBr$_3$ perovskites: A hybrid functional study  
MANJARI JAIN (Presenter), SASWATA BHATTACHARYA, Physics, Indian Institute of Technology Delhi — Hybrid inorganic-organic perovskites (HIOPs) solar cells have attracted intense attention because of its high carrier lifetime, long diffusion length and low manufacturing cost. Formamidinium Lead Bromide (FAPbBr$_3$), a HIOPs is immensely promising class of material for photovoltaic application. However, due to presence of hazardous Pb, its application to real life is hindered. Therefore, its our profound interest to understand if substitution of adatoms (e.g. Sn, Ge) or creation of Pb-vacancy [Vc] or doing the same simultaneously will be effective considering its efficiency in solar cell devices.

We address here the role of Sn substitution and Pb-Vc in regulating stability using state-of-the-art hybrid density functional theory. The explicit role of spin orbit coupling (SOC) and electron self interaction error are discussed. We find while SOC has significant role in regulating electronic bands, it doesn't affect the relative hierarchy of thermodynamic stability of different configurations of FAPb$_{(1-x-y)}$Sn$_x$Vc$_y$Br$_3$. However inclusion of electron self interaction error is absolutely important to estimate formation energy of configurations correctly. The Spectroscopic Limited Maximum Efficiency (SLME) is compared of the most stable defected system with respect to the pristine FAPbBr$_3$. 
1:27PM G21.00012: Absence of large valence band Rashba splitting in metal halide perovskites  
OLIVER RADER (Presenter), MARYAM SAJEDI, MAXIM KRIVENKOV, DMITRY MARCHENKO, ANDREI VARYKHALOV, JAIME SÁNCHEZ-BARRIGA, Helmholtz-Zentrum Berlin, ANOOP CHANDRAN, IRENE AGUILERA, Forschungszentrum Jülich — Organic and inorganic lead halide perovskites share the same properties of high efficiency in energy conversion and high spin-orbit interaction. For both, a large Rashba effect has been invoked to be responsible for the high efficiency by prohibiting direct recombination. In the valence band of methylammonium lead bromide a static Rashba effect has been reported by angle-resolved photoemission (ARPES) and circular dichroism with giant values of 0.7 to 1.1 eV nm [1]. We present precise ARPES band dispersion measurements of methylammonium lead bromide and cesium lead bromide to show that a Rashba effect of the reported size does not exist. Moreover, we use spin-resolved ARPES to confirm the conclusions. We also observe a large circular dichroism effect and demonstrate that this effect does not imply any measurable spin polarization and Rashba effect. Our results exclude a static Rashba effect in the valence band as origin of the high efficiency of metal halide perovskites.  

1:39PM G21.00013: Simulations of the electronic stopping power in perovskites*  
MARIO BORUNDA (Presenter), Oklahoma State University-Stillwater — Electronic stopping power describes the energy transfer rate to electrons in material during ion irradiation. We use time-dependent density functional theory to calculate electronic stopping power in triple-cation perovskites (formamidinium, methylammonium, and cesium). These materials have some of the highest power conversion efficiencies for perovskite-based photovoltaics. From simulations we can estimate the stopping process of ions and this would have implications for the use of photovoltaic devices for space missions.  

*This material is based upon work supported by the National Aeronautics and Space Administration under Agreement No 80NSSC19M0140 issued through NASA Oklahoma EPSCoR.
1:51PM G21.00014: Role of Cu deficient layer in chalcopyrite based solar cells  ABHISHEK SHARAN (Presenter), Univ of Delaware, JOEL VARLEY, Lawrence Livermore National Laboratory, ANDERSON JANOTTI, Univ of Delaware — Chalcopyrites are a demonstrated material platform for realizing efficient thin-film photovoltaics, with the most well-known Cu(In,Ga)Se$_2$ (CIGS) based solar cells exceeding 23%. The presence a Cu-poor phase layer between the absorber and buffer layers in CIGS solar cells is known to enhance device performance, however, the overall properties and role of very thin layer remain poorly understood. Using first principles calculations based on density functional theory with screened hybrid functionals, we explore the electronic structure and stability of a series ordered vacancy compounds (or OVCs) as a model for the Cu-poor phase layer. We calculate band offsets between the OVCs and defect-free chalcopyrite Cu and Ag based compounds (ABX$_2$ where A = Cu, Ag; B = In, Ga, Al and X = S, Se). Using AB$_3$X$_5$ and AB$_5$X$_8$ stoichiometries as model OVC systems, we report on the variation of the band gap with A/B ratio and discuss the trends in other Cu and Ag-based chalcopyrites beyond CuInSe$_2$. We additionally perform device-level simulations to understand the implications of formation of OVCs, finding that valence band offsets of OVCs are favorable for hole transport, while the conduction band offsets of chalcopyrites beyond CuInSe$_2$-based absorbers may be detrimental to device performance.

Tuesday, March 3, 2020 11:15 AM - 1:39 PM

Session G22 DBIO DSOFT: Biopolymers: Nucleic Acids and Structural 303 - Ralf Bundschuh, Ohio State Univ - Columbus

11:15AM G22.00001: Autonomous synthesis and assembly of a ribosomal subunit on a chip  MICHAEL LEVY (Presenter), REUVEN FALKOVICH, SHIRLEY S. DAUBE, ROY H. BAR-ZIV, Weizmann Institute of Science — Ribosome biogenesis is an efficient and complex assembly process that has not been reconstructed outside a living cell so far, yet is the most critical step for establishing a self-replicating artificial cell.

We recreated the biogenesis of Escherichia coli's small ribosomal subunit by synthesizing and capturing all its ribosomal proteins and RNA on a chip. Surface confinement provided favorable conditions for autonomous step-wise assembly of new subunits, spatially segregated from original intact ribosomes. Our real-time fluorescence measurements revealed hierarchal assembly, cooperative interactions, unstable intermediates, and specific binding to large ribosomal subunits.

Using only synthetic genes, our methodology is a crucial step towards creation of a self-replicating artificial cell and a general strategy for the mechanistic investigation of diverse multi-component macromolecular machines.
The formation of filopodia bridge and intercellular nanotube: A Critical rule of torque and restorative force.*  O-CHUL LEE (Presenter), MINHYEOK CHANG, JAEHO OH, JONG-BONG LEE, JAE-HYUNG JEON, Pohang Univ of Sci & Tech — In mammalian cells, a network of intercellular membrane nanotubes enables long-distance communication which is an intercellular transfer of cytoplasmic molecules and even organelles and viruses. The main component in filopodia which constitutes membrane intercellular nanotubes is consists of bundled actin filamentous. Also, several studies have confirmed the dynamic behavior of the filopodia which are undergoing restorative force by myosin II and torque by myosin V. Using a fluorescence imaging method, we have found that filopodia grown from two adjacent cells form the helical structure resulting. To understand the mechanism of forming the intercellular nanotube, we model a filopodium as a bundle of wormlike chains whose net persistence length is consistent with the value measured by our optical tweezers experiment. In this study, we quantitatively investigate the conformation, stability, and dynamics of the filopodia in comparison with the experiment by using the Langevin dynamics simulation. From the simulation results, we propose a region of a magnitude of tension and torque applied to the filopodia to form the nanotube.

A novel coarse-grained energy functions for RNA folding*  DONG ZHANG (Presenter), SHI-JIE CHEN, Univ of Missouri - Columbia — Coarse-grained models combined with effective sampling techniques are now poised to address a wide range of problems in biological systems. An accurate coarse-grained force field is crucial for quantitative modeling of structure, dynamics, and function. We recently developed a novel approach to extract RNA coarse-grained energy functions from the structural database. The key ingredient of the approach is to stepwise build the correlations between the different interactions and the inherent chain connectivity and excluded volume interactions through an iterative construction of the reference states. The novel approach allows us to extract energy functions from the inverse Boltzmann law. The validity of this approach is supported by the close agreement between the simulated distributions for all the structural parameters and those observed from the experimental structure database. Benchmark tests on tertiary structure folding and 3D structure predictions show comparable or much improved predictions than existing coarse-grained models. This novel method for the treatment of many-body correlation effects can be easily transferred to other computational biology problems.

Non-ergodic transport and conformational dynamics of DNA in biomimetic cytoskeleton networks*  

JONATHAN GARAMELLA (Presenter), GINA AGUIRRE, Univ of San Diego, KATHRYN REGAN, Biomedical Engineering, Boston University, RYAN J. MCGORTY, RAE M ROBERTSON-ANDERSON, Univ of San Diego — Macromolecular crowding is an increasingly relevant biophysical phenomenon that affects drug delivery, protein function, and intracellular transport. Of particular interest is the influence that cytoskeletal filaments have on the transport and conformational dynamics of large DNA molecules. Here, we use single-molecule conformational tracking (SMCT) to elucidate the transport properties and conformational dynamics of linear and relaxed circular (ring) DNA in in vitro composite networks of actin and microtubules with variable types of crosslinking. Specifically, we investigate the impact of crosslinking actin to actin, microtubules to microtubules, and actin to microtubules. While both linear and ring DNA undergo anomalous subdiffusion in all networks, the transport properties are heavily influenced by DNA topology. Linear DNA chains are compacted and display a single mode of subdiffusion, while ring DNA polymers are swollen and exhibit biphasic subdiffusion suggestive of transient threading by the biomimetic cytoskeleton. These results are bolstered by non-Gaussian van Hove distributions and non-ergodic behavior of both DNAs, with the transport of ring DNA molecules becoming less ergodic than their linear counterparts at longer times.

Single nucleotide polymorphisms affect RNA-protein interactions at a distance through modulation of RNA secondary structures*  

RALF BUNDSCHUH (Presenter), ELAN SHATOFF, Department of Physics, Ohio State University — RNA-protein interactions play an important role in regulating gene expression. Since RNA-protein interactions are affected by RNA secondary structure, single nucleotide polymorphisms in the vicinity of protein binding sites can affect these interactions. This provides a mechanism for single nucleotide polymorphisms outside coding regions and outside the actual protein binding sites to convey a phenotype. Here, we use a modified version of the Vienna RNA folding package and PAR-CLIP data for HuR (ELAVL1) in humans to characterize the genome-wide effect of single nucleotide polymorphisms on HuR binding and show that they can have a many-fold effect on the affinity of HuR binding to RNA transcripts from tens of bases away. We also find that the effect of single nucleotide polymorphisms on protein binding appears to be under selection, with the minor alleles tending to make it harder for a protein to bind.

12:15PM G22.00006: COARSE-GRAINED MODELING OF DNA PLECTONEME FORMATION IN THE PRESENCE OF BASE-PAIR MISMATCHES  PARTH RAKESH DESAI (Presenter), SIDDHARTHA DAS, University of Maryland, College Park, KEIR C NEUMAN, National Institutes of Health — Defects in double stranded DNA can arise from mismatched base pairs. In vivo, these must be rapidly repaired since they affect a variety of cell processes. Here we use molecular dynamics to study the effect of mismatched bps on DNA supercoiling. Magnetic tweezers-based studies of DNA supercoiling have shown that in DNA harboring a single mismatch, the plectoneme always localizes at the mismatch. These studies were conducted at relatively high salt concentrations (>0.5M). Theoretical studies have predicted that under physiological salt concentrations of ~0.2M, plectoneme localization becomes probabilistic. However, both approaches are currently limited to positively supercoiled DNA. We develop a simulation framework using the oxDNA model to study the effect of mismatches on both positively and negatively supercoiled DNA. We find that for a positively supercoiled DNA, the oxDNA framework can reproduce the experimentally observed plectoneme pinning at high force and high salt concentrations. Under physiological salt concentrations (0.2M), we find that the plectoneme localization at the mismatch becomes probabilistic. The utility of the simulation approach is highlighted by the ability to quantify the effect of mismatches on the motion of plectonemes along the DNA molecule.

12:27PM G22.00007: A quantitative model of temperature actuated DNA origami nanocaliper constructs*  KYLE CROCKER (Presenter), Department of Physics, The Ohio State University, JOSHUA JOHNSON, Interdisciplinary Biophysics Graduate Program, The Ohio State University, CARLOS E CASTRO, Department of Mechanical and Aerospace Engineering, The Ohio State University, RALF BUNDSCHUH, Department of Physics, The Ohio State University — Manipulation of temperature can be used to actuate gold nanoparticle incorporated into DNA origami nanocalipers. We develop a physical model of this system that uses partition function analysis of the interaction between the nanocaliper and nanoparticle to predict the probability that the nanocaliper is open at a given temperature. The model agrees well with experimental data, and the comparison between model and experiment reveals surprising insights into the nanocaliper-nanoparticle system. For instance, geometric constraints on the system are suggested. Additionally, the model predicts experimental conditions that allow the actuation temperature of the nanocaliper to be tuned over a wide range of temperatures from 20°C to 60°C. This combination of physical insight and predictive potential is likely to inform future designs that integrate nanoparticles into dynamic DNA origami structures. Furthermore, our modeling approach could be expanded to consider the incorporation, stability, and actuation of other types of functional elements or actuation mechanisms integrated into nucleic acid devices.

*This material is based upon work supported by the National Science Foundation under Grant No. DMR-1719316, as well as the Department of Energy grant DE-SC0017270.
**12:39PM G22.00008: A dynamic model of DNA Supercoiling**  BIAO WAN (Presenter), JIN YU, XINLIANG XU, Beijing Computational Science Res Ctr — The dynamics of DNA supercoiling is important for many biological functions of DNA, such as gene expression regulation. In this investigation we first studied DNA supercoiling generation through a Brownian dynamics simulation of DNA, which is modeled as a discrete worm-like chain. Two well-separated time scales are observed: mechanical balance along the DNA can be regarded as instantaneous (10^{-3}−10^{-2} ms) when compared to the global configuration change of the DNA supercoil structure (>10^0 ms). Based on this time separation, we developed a new model where the fast mechanical balancing dynamics are coarse grained. While the numerical simulation of DNA supercoil dynamics based on this model can be shown to fully reproduce DNA dynamical behavior above millisecond time scale, the computational efficiency is greatly improved. In our example of a DNA segment of 6000 base pairs, simulation based on the new model is times faster than the original Brownian dynamics simulations, making numerical study of DNA dynamics at biologically relevant time scales (e.g. 1−10 sec) possible.

**12:51PM G22.00009: Real-Time Tracking and Quantification of Transposable Element Activity***  DAVNEET KAUR (Presenter), Physics, University of Illinois at Urbana-Champaign, GLORIA LEE, University of San Diego, NICHOLAS SHERER, ELLIOT URRIOLA, Physics, University of Illinois at Urbana-Champaign, HNEIL KIM, University of California, Berkeley, CHI XUE, Physics, University of Illinois at Urbana-Champaign, K. MICHAEL MARTINI, Emory College, NIGEL GOLDENFELD, Physics, University of Illinois at Urbana-Champaign, THOMAS E KUHLMAN, Physics, University of California, Riverside — Transposable elements (TEs), or jumping genes, are DNA sequences that can change their position in a genome using a cut-and-paste or copy-and-paste mechanism. They are fundamental building blocks of all genomes, accounting for large fractions of genomic masses, and may have played a major role in the emergence of genetic diversity and function. Even so, many open questions remain regarding their differential abundance among organisms, the functions of their individual proteins, rates of protein activity and transposition and the effects of TEs on their hosts. To address these unanswered questions, we have constructed and released inducible TEs in bacteria to quantify their rates of activity and physiological effects on their hosts. To quantify dynamics, we've designed fluorescent visualization and quantification techniques to make real time high resolution observations of protein expression and transposition events as they occur in living cells. We show that we can obtain a deeper understanding of the roles of TEs and their individual proteins through our analysis.

1:03PM G22.00010: Simulating the Polarization Effects of Gas-Phase Nucleic Acids*  
CHRISTOPHER MYERS (Presenter), Physics, University At Albany, ALAN CHEN, Chemistry, University At Albany —  
Molecular dynamics (MD) simulations coupled with ion mobility spectrometry (IMS), a gas-phase extension to mass spectrometry that further filters analytes by conformation, allows researchers to perform three dimensional structural elucidation of nucleic acids. As opposed to neutral liquid phase MD simulations where electrostatic interactions are considered to be relatively weak and short ranged, highly charged, gas phase IMS simulations require a stronger description of Coulomb and polarization effects. In the work presented here, we explore the dynamical properties an appropriately tuned electrostatic force field for gas phase nucleic acids should replicate. Based off of density functional theory calculations of small oligonucleotides, we examine how one could adjust the partial charges throughout an MD simulation to more accurately replicate Coulomb interactions for charged and protonated nucleic acids.  
*This work is funded by NSF grant number MCB1651877.

1:15PM G22.00011: Existence of the B-Form DNA helix in nanoDNA liquid crystals and its variation due to aggregate assembly*  
GREGORY SMITH (Presenter), University of Colorado, Boulder, TOMMASO FRACCIA, ESPCI Paris, Intitut Pierre-Gilles de Gennes, MIKHAIL ZHERNENKOV, NSLS-II, Brookhaven National Laboratory, TOMMASO BELLINI, University of Milan, NOEL ANTHONY CLARK, University of Colorado, Boulder —  
We show using diffraction of a synchrotron X-ray microbeam that liquid crystalline aggregates of 12mer nanoDNA, such as the Drew-Dickerson Dodecamer (DD), demonstrate a B-form DNA double helix with a comparable degree of order to that seen in longer DNA, such as the calf-thymus DNA used by Rosalind Franklin to produce the historic Photo 51. This finding is significant because it shows that B-form helical order persists in liquid crystals of DD even though the backbone of the column contains a double-strand break at every twelfth position and the DD segments are not part of a full structured crystal. The coherence of the B-form helix is influenced by the mode of aggregate self-assembly, where aggregates assembled by a base-paired sticky-end produce much longer helical correlation lengths than those formed by hydrophobic blunt-ends. Finally, we found that aggregates of blunt-end 4mer oligomers shorter than half of a single B-form helical turn no longer display the B-form helical diffraction pattern but order with a different structure. This study gives fundamental insight into the extent to which the classical DNA helix is affected by discontinuity in the polymer backbone.

It is known that several kinds of paper (including the common copy paper) increase in thickness when stretched. Previously, we examined several commercially available papers and found this behavior in some of them. We also devised, utilizing a few other reports, a mechanistic explanation for the origin of this auxetic response. In this research, we apply our understanding of this mechanism to construct auxetic paper handsheets. Key structural parameters of a nonwoven cellulose fiber network in paper – fiber length, sheet thickness and crosslinking density, that were previously predicted to affect the magnitude and sign of Poisson’s ratio, were altered to produce a range of handsheets. It was found that longer fibers, crosslinking density, extent of refining, and sheet thickness significantly affect the magnitude of auxetic response in paper.

Session G23 DBIO GSNP: Evolutionary and Ecological Dynamics I:
Population Ecology 304 - Jeffrey Gore, Massachusetts Institute of Technology MIT - Tag(s): Focus

11:15AM G23.00001: The price of a shortcut [Invited] WENYING SHOU (Presenter), Basic Sciences, Fred Hutch Cancer Research Center — I will discuss the importance of quantitative mathematical modeling in biology. I will also experiment with a different presentation style where scientific work is described through story-telling. My talk will be accessible to specialists who study physical biology and to general audience with little knowledge of biology. I also hope to get feedback from the audience on how well this style worked for them.
11:51AM G23.00002: Long-term Nutrient Cycling in a Materially Closed Ecosystem  

LUIS DE JESÚS ASTACIO (Presenter), ZEQIAN LI, KAUMUDI PRABHAKARA, SEPPE KUEHN, Physics, University of Illinois at Urbana-Champaign — Closed Microbial Ecosystems (CES) are hermetically sealed microbial communities that support self-sustaining nutrient cycles using only light as an input. CESs have been proposed as controlled model systems to understand the principles governing ecosystem organization and persistence. However, we do not yet understand how the nutrient cycling capabilities of a CES depend on its community structure and composition. To address this question, we present a new method for making precision measurements of carbon cycling in CES using low-cost piezoresistive pressure sensors. With these devices, we quantify carbon cycling rates in a set of CESs over periods of months. Our data show that previously studied synthetic CES comprised of model organisms exhibit declining carbon cycling rates on long-timescales. We go on to self-assemble CESs using the phototrophic alga *Chlamydomonas reinhardtii* combined with complex, soil-derived, bacterial communities. We find that these CESs persistently cycle carbon on timescales of many weeks. Also, we characterize the limiting nutrients in these CESs as well as their community-level metabolic capabilities. Finally, we use next-generation sequencing to characterize the taxonomic and metagenomic composition of these persistent microbial biospheres.

12:03PM G23.00003: Growth and form control population dynamics of cellular aggregates*

ALEXANDER GOLDEN (Presenter), KIRILL S KOROLEV, Physics, Boston University — While the colony morphology reflects the interplay of biophysical processes such as nutrient diffusion, motility, and growth. How these processes control genetic correlations within the population remains an open question. To understand how growth morphology influences evolutionary dynamics, we have developed a numerical model of two-dimensional colonies in which microbes grow by consuming a diffusible nutrient and have a density-dependent motility. We show that this model can reproduce a diverse family of shapes observed in the experiments. Many of these morphologies exhibit a qualitatively different pattern of genetic drift compared to microbial colonies with a moderately rough front, which have been the focus of previous work. We report the scaling exponents for both morphological and genetic quantities for each of the growth regime. Most importantly, we show the consequences of the transition from pulled to pushed expansions in two-dimensional models with nutrient diffusion.

12:15PM G23.00004: Synergistic effects of nitrogen and phosphorous on the growth of algal cells revealed by a microfluidic platform*  
FANGCHEN LIU (Presenter), MOHAMMAD YAZDANI, NICOLE GOULDING WAGNER, BETH A. AHNER, MINGMING WU, Cornell University — A sudden growth of photosynthetic algal cells causes Harmful Algal Bloom (HAB), depleting water resources and disrupting the balance of aqua ecosystems. HAB is an emerging environmental problem exacerbated by climate change and population growth. Despite the urgency of the problem, there still lacks a systematic understanding of the environmental conditions (physical, chemical, and biological) under which HABs occur. In this presentation, we studied the growth of a model algal strain, *Chlamydomonas reinhardtii*, under a dual concentration gradient of nitrogen (N) and phosphorous (P) and found that N and P synergistically promoted algal cell growth. Interestingly, no discernible response was observed under single nutrient gradient. We also demonstrated the potential application of the newly developed microfluidic platform that integrated the array microhabitat format with dual gradient generation, enabling fast screening of environmental factors for algal growth studies. Future investigations will include the dynamics of bacterial community under controlled environmental condition.

12:27PM G23.00005: Dynamics of prey-predator: effect of cooperative interaction and inertial forces*  
DIPANJAN CHAKRABORTY (Presenter), RUMI DE, IISER Kolkata — A swarm of preys when attacked by a predator is known to rely on their cooperative interactions to escape. We present a simple theoretical model to investigate the effect of cooperative interactions on the survival chances of a prey group while chased by a predator. Our study shows that very short-range or very long-range interactions are not beneficial for preys to escape. However, in the intermediate range of interaction, an optimality criterion can be established where the survival probability of the prey group is maximum. We further explore the effect of inertial forces on the survival chances and escape trajectories of the prey group. Interestingly, we observe a transition from non-survival to survival of the prey group as a function of increasing predator mass. Our analysis also shows that prey group size and predator strength have an immense effect on this survival regime.

12:39PM G23.00006: Representing spatially extended ecological oscillators by kinetic Ising models with memory*  VAHINI REDDY NAREDDY (Presenter), University of Massachusetts Amherst, JONATHAN MACHTA, University of Massachusetts Amherst, Santa Fe Institute, KAREN ABBOTT, Case Western Reserve University, SHADISADAT ESMAEILI, University of California at Davis, ALAN HASTINGS, University of California at Davis, Santa Fe Institute — Synchronous behavior in spatially-extended ecological systems can be modeled by noisy, coupled oscillators. If the individual oscillators are in a two-cycle regime, the transition to synchrony as a function of noise strength and coupling strength has been shown to be in the Ising universality class [1]. On the other hand, a nearest neighbor Ising model may not provide an accurate description of non-universal properties. In this talk we will discuss the question of accurately representing a system of coupled, noisy two-cycle oscillators by an Ising model. We show that an accurate representation requires a kinetic Ising model with a self-interaction (memory) term. Even if this kinetic Ising model with memory includes only nearest-neighbor couplings in the dynamics, its equilibrium states are described by a Hamiltonian with more distant neighbor coupling and multi-spin terms. Using maximum likelihood methods we are able to infer an accurate kinetic Ising representation of synthetic data from a noisy lattice map system. We also discuss applications to field data in ecology.

*This work is supported in part by NSF grant DMS-1840221

12:51PM G23.00007: Ocean currents promote rare species diversity in protists  PAULA VILLA MARTIN (Presenter), ALES BUCEK, TOM BOURGUIGNON, SIMONE PIGOLOTTI, Okinawa Inst of Sci & Tech — Oceans host communities of plankton composed of a huge number of rare species that, as estimated in metagenomic studies, decay as a steep power law of their abundance. We propose that the way oceanic currents limit protists dispersal is a key factor of such biodiversity pattern. We introduce a spatially explicit coalescence model able to reconstruct species ancestry and diversity in the presence of currents. Our model predicts a steep power law decay of the species abundance distribution and a steep increase of the number of observed species with sample size. Metagenomic studies of planktonic protist communities show excellent agreement with our results.
1:03PM G23.00008: Spatial segregation as a necessity for beneficial gene loss in cross-feeding bacterial communities: a kinetic perspective on the Black Queen Hypothesis
MARIO DI SALVO (Presenter), SIMA SETAYESHGAR, JAMES MCKINLAY, Indiana Univ - Bloomington —
Cross-feeding communities are common across diverse environments, such as soil, water, and host microbiomes. The Black Queen Hypothesis (BQH) [1] asserts that some metabolic functions are leaky and thus provide a public resource within a community. The public resource allows some community members to lose genes for the production of that resource as long as at least one member continues to produce the resource. Nitrogen fixation as a process that leaks ammonium is used as an example to explain why only certain prokaryotes encode nitrogenase. We explore the emergence of mutualistic cross-feeding in bacterial cocultures in the context of the BQH. We pair a slow-growing nitrogen-fixing cooperator with fast-growing fermentative partners that can either also fix nitrogen gas or require the product, ammonium. We demonstrate that spatial heterogeneity is necessary for the emergence of a partner strain that loses nitrogen-fixation.

1:15PM G23.00009: Localization transitions in age-structured populations
TAKASHI NOZOE (Presenter), EDO KUSSELL, Biology, New York University —
We discuss age-structured population models that exhibit a range of collective phenomena including phase transitions and population-level oscillations. We present an analysis that predicts the lineage properties of single cells, and demonstrate how the optimal lineage in a population undergoes a qualitative change in its statistical properties as model parameters are varied past a localization transition point that is analytically computed. We observe aging dynamics of the population in the localized phase, and illustrate connections with other problems in evolutionary dynamics.

1:27PM G23.00010: Formation of Phage Lysis Patterns and Implications on Co-Propagation of Phages and Motile Host Bacteria
JING CHEN (Presenter), Virginia Tech —
Coexistence of bacteriophages, or phages, and their host bacteria plays an important role in maintaining the microbial communities. In natural environments with limited nutrients, motile bacteria can actively migrate towards locations of richer resources. Although phages are not motile themselves, they can infect motile bacterial hosts and spread in space via the hosts. Therefore, in a migrating microbial community coexistence of bacteria and phages implies their co-propagation in space. Here, we combine an experimental approach and mathematical modeling to explore how phages and their motile host bacteria coexist and co-propagate. When lytic phages encountered motile host bacteria in our experiments, a sector-shaped lysis zone formed. Our mathematical model indicates that local nutrient depletion and the resulting inhibition of proliferation and motility of bacteria and phages are the key to formation of the lysis pattern. The model further reveals the straight radial boundaries in the pattern as a tell-tale sign for coexistence and co-propagation of bacteria and phages. Emergence of such a pattern, albeit insensitive to extrinsic factors, requires a balance between the intrinsic physiology of phages and bacteria, which likely results from co-evolution of phages and bacteria.
1:39PM G23.00011: Spatial competition of toxin-secreting strains of yeast  ANDREA GIOMETTO (Presenter), ANDREW MURRAY, DAVID R. NELSON, Harvard University — Antagonistic interactions are widespread among microbes and can affect the structure and composition of microbial communities. Theoretical models of well-mixed population genetics with antagonistic interactions predict that a stronger competitor can invade a weaker one only if its initial population is larger than a critical inoculum size. In spatially-extended populations, the invasion of one competitor by another can be mapped to a nucleation problem and the invasion is predicted to be successful only above a critical nucleation size. To test these predictions, we have genetically engineered two strains of the baker's yeast *Saccharomyces cerevisiae* to release two different toxins, whose production rates we can vary independently. These strains allowed us to study how antagonistic interactions affect the population dynamics and population genetics of spatially-structured populations at different levels of toxin production, i.e. at different relative strengths of the two competitors. We show that, both in spatially-structured and in well-mixed populations, a toxin-producing strain can displace another toxin-producing strain only if the initial inoculum is larger than a critical threshold, even if the invader strain enjoys a selective advantage.

Tuesday, March 3, 2020 11:15 AM - 2:03 PM

Session G24 GSNP DBIO: Noise-Driven Dynamics in Far-From-Equilibrium Systems II 401 - Jeffrey Weiss, University of Colorado, Boulder

11:15AM G24.00001: Minimal Model for Intermittent Dynamics and "Turbulence" in Many-Body Systems*  GURAM GOGIA (Presenter), WENTAO YU, JUSTIN BURTON, Emory University — Complex systems are known to exhibit emergent properties that are missing on the constituent level. One particular property shared by many seemingly unrelated complex systems is intermittent switching between distinct dynamical states. Inspired by our previous experimental findings [1], here we present computational results for a particle-based system that exhibits intermittent switching between two distinct phases. The emergent dynamics are a direct consequence of coupling between structural disorder arising from particle polydispersity, inertial dynamics, and external forcing. Modelling the orthogonal mechanical energies of the system using ODEs with both noise and coupling terms based on kinetic arguments surprisingly results into predator-prey-like interactions. Such equations have recently been employed to describe intermittent turbulence in a pipe flow [2]. The only non-dimensional number derived from our equations resembles the Reynolds number in fluid flow and accurately predicts where intermittent dynamics are manifested.

*NSF, DMR-1455086
**11:27AM G24.00002: Stochastic transitions between phase-locked steady states in RF-irradiated graphene Josephson junctions**  
* TREVYN LARSON (Presenter), LINGFEI ZHAO, ETHAN ARNAULT, Physics, Duke University, MING-TSO WEI, Physics, University of Maryland, ANDREW SEREDINSKI, Physics, Duke University, HENGMING LI, Physics, Appalachian State University, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, FRANCOIS AMET, Physics, Appalachian State University, GLEB FINKELSTEIN, Physics, Duke University — We investigate the Shapiro steps in a graphene-based Josephson junction with large gap MoRe leads. A wide variety of patterns are obtained, depending on the carrier density, temperature, RF frequency, and magnetic field. A particularly interesting regime of intermediate driving power is identified, in which the zero voltage state becomes unstable even at zero bias, and the junction spontaneously develops a voltage $V = \pm hf/2e$, which could persist for a several hours. We study the switching time between the $\pm hf/2e$ states as a function of applied power and temperature, and find a novel non-monotonic regime, in which the switching time between these attractors demonstrates a pronounced minimum at intermediate temperatures.

*Measurements conducted by T.L. and E.A were supported by Division of Materials Sciences and Engineering, Office of Basic Energy Sciences, U.S. Department of Energy, under Award No. DE-SC0002765. M-T.W. and A.S. performed lithographic fabrication and characterization of the samples with the support of NSF awards ECCS-1610213 and DMR-1743907. L.Z. and G.F. were supported by ARO Award W911NF16-1-0122. H.L. and F.A. acknowledge the ARO Award W911NF-16-1-0132.

BERNARDO SPAGNOLO (Presenter), Physics and Chemistry, Univ of Palermo — The noise-driven dynamics of three far-from-equilibrium systems are investigated: (i) transient dynamics in unstable potential and in Josephson junctions with Lévy noise; (ii) escape from a quantum dissipative metastable state in the presence of an external driving; (iii) the switching dynamics in a stochastic model of memristor.

We obtain: (i) exact analytical results of the residence time in the presence of Lévy flights in unstable potential profile, and noise enhanced stability phenomenon is observed in the system investigated and in JJs. (ii) a nonmonotonic behavior of the escape time versus the system-bath coupling, the temperature, and the frequency of the driving. The quantum noise enhanced stability phenomenon is observed in the system investigated. (iii) the nonstationary distribution and relaxation time of the stochastic model of memristors, which shows a nonmonotonic dependence, with a maximum, on the intensity of fluctuations.

11:51AM G24.00004: Anomalous Phase Dynamics of Driven Graphene Josephson Junctions
SANDESH KALANTRE (Presenter), FAN YU, MING-TSO WEI, University of Maryland, College Park, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science 1-1 Namiki, Tsukuba, 305-0044, Japan, MIGUEL HERNANDEZ-RIVERA, FRANCOIS AMET, Department of Physics and Astronomy, Appalachian State University, Boone, NC, USA, JAMES WILLIAMS, University of Maryland, College Park — Josephson junctions with weak-links of exotic materials allow the elucidation of the Josephson effect in previously unexplored regimes. In this work, we report on DC and AC Josephson effect of high-mobility, hexagonal boron nitride encapsulated graphene Josephson junctions. We measure phase-locked Shapiro steps on the application of RF radiation. The shape of resistive transitions between the steps is anomalous in the form of extended nodes. Moreover, an unexpected bistability between ±1 steps is observed with switching times on the order of seconds. A critical scaling of a bistable state with DC current and RF power is measured directly from the switching time, allowing for a comparison to numerical simulations. We show such intermittent chaotic behavior is a consequence of the nonlinear dynamics of underdamped junctions and has a sensitive dependence on the current-phase relation. We numerically investigate the switching time scaling as a consequence of the interplay between noise level and basin structure of the solutions. This work draws connections between nonlinear phenomena in dynamical systems and their implications for ongoing condensed matter experiments exploring topology and exotic physics.

12:03PM G24.00005: A theoretical model for ionic transport in a viscosity gradient*
DEREK STEIN (Presenter), BENJAMIN N WIENER, Physics, Brown University — We recently discovered that imposing a viscosity gradient across a nanofluidic channel made of glass causes ionic current to flow. The current is evidently carried by positively charged counterions in the electric double layers near the channel walls drifting toward the lower viscosity side. We present an explanation based on the Maxwell-Stefan (MS) theory of diffusion. Within the MS theory, transport of a given species is driven by a gradient in its chemical potential, and that driving force is balanced by a friction force with every other molecular species. Relating the MS theory to our nanofluidic experiments, we consider a fluid comprising a viscous fluid, a thin fluid, and counterions. The viscous and thin components of the mixture flow in opposite directions inside the channel, and as they do, each one exerts a frictional force on the counterions. There is a net motion of those counterions in the direction of decreasing viscosity because the drag coefficient with the viscous component is larger than the coefficient with the thinner component. There is also no mystery where the energy to drive the current comes from: It comes from the free energy of mixing of the viscous and thin fluids.

12:15PM G24.00006: Pulling cargo increases the precision of molecular motor progress
AIDAN IVAR BROWN, Physics, University of California, San Diego, DAVID SIVAK (Presenter), Physics, Simon Fraser University — Biomolecular motors use free energy to drive a variety of cellular tasks, including the transport of cargo, such as vesicles and organelles. We find that the widely used "constant-force" approximation for the effect of cargo on motor dynamics leads to a much larger variance of motor step number compared to explicitly modeling diffusive cargo, suggesting the constant-force approximation may be misapplied in some cases. We also find that, with cargo, motor progress is significantly more precise than suggested by a recent result. For cargo with a low relative diffusivity, the dynamics of continuous cargo motion—rather than discrete motor steps—dominate, leading to a new, more permissive bound on the precision of motor progress which is independent of the number of stages per motor cycle.

DANIEL SEARA (Presenter), BENJAMIN B MACHTA, MICHAEL MURRELL, Yale University — Due to the lack of symmetries and variational principles, non-equilibrium systems have been difficult to treat theoretically. Recent work has focused on measuring entropy production rates as a measure of a system's distance from equilibrium, but little connection has been made between entropy production and the complex, spatiotemporal dynamics that arise at different time and length-scales in driven systems. We present a generic method for estimating entropy production rates from stochastic time series data for both random variables and fields while providing insight into the dissipative processes underlying their dynamics. Our method provides insight into the relationship between pattern formation and dissipation in mesoscopic, driven reaction-diffusion systems. Importantly, this technique does not depend at all on the underlying system and can be used with data in any number of spatial dimensions.

12:39PM G24.00008: Learning the Non-Equilibrium Dynamics of Brownian Movies
FEDERICO GNESOTTO, GRZEGORZ GRADZIUK, Ludwig Maximilian University of Munich, PIERRE RONCERAY, Princeton University, CHASE BROEDERSZ (Presenter), Ludwig Maximilian University of Munich — Soft living systems such as cytoskeletal networks, membranes, and tissues are driven out of thermodynamic equilibrium by internal enzymatic activity. Measuring and characterizing the non-equilibrium properties in these systems is a major challenge, owing to the large number of interacting degrees of freedom. Typically, the experimental characterizations of such systems rely on tracking the trajectories of embedded or endogenous probes. However, it is not clear how to select appropriate tracer probes and how this choice affects the resulting characterization; in general, it is unknown a priori which degrees of freedom are most informative about non-equilibrium activity in the system. In this talk, we present a new approach that does not rely on the tracking of probes in the system. Instead, we directly learn the non-equilibrium dynamics from a Brownian movie of a fluctuating soft assembly, yielding force fields and entropy production rates. Our approach is based on a principled analysis that reduces the dimensionality of the system by identifying the most dissipative components. We will discuss how this approach performs in different scenarios inspired by cytoskeletal networks.
12:51PM G24.00009: Spectral decomposition of irreversibility reveals structure of nonequilibrium activity in biological systems  ALEXANDRU BACANU (Presenter), JAMES F PELLETIER, YOON JUNG, Massachusetts Institute of Technology MIT, JORDAN HOROWITZ, University of Michigan, NIKTA FAKHRI, Massachusetts Institute of Technology MIT — Biological systems, such as cytoskeletal networks, exhibit stochastic mechanical fluctuations on mesoscopic scales which can violate detailed balance. The spatiotemporal structure of nonequilibrium activity on these scales remains unexplored, due to a lack of methods able to reliably quantify irreversibility. To probe activity in both space and time, we image spatially extended single-walled carbon nanotubes (SWNTs) embedded in actin-intact Xenopus cytoplasmic extract. Using normal mode decomposition of filament shape fluctuations, we infer the structure of the actomyosin-driven mechanical fluctuations. Metrics for irreversibility based on normal mode correlation functions quantify the spatiotemporal extent of nonequilibrium activity. To estimate the noise floor of our analysis, we compare our results to the fluctuations of SWNTs in an equilibrium, entangled F-actin gel. By altering network architecture and generating chemostatted ATP reservoirs, we probe the response of nonequilibrium activity to distinct perturbations. Our analysis quantifies the spatiotemporal structure of irreversibility on mesoscopic scales and shows it is affected by network mechanics and its coupling to the ATP chemical reservoir.

1:03PM G24.00010: Noisy driven oscillators: Adaptive drives break the fluctuation-dissipation theorem  JANAKI SHETH (Presenter), ALEX LEVINE, DOLORES BOZOVIC, Physics, UCLA — The steady-state dynamics of complex nonlinear systems include limit cycles in which the dynamic variables trace a closed path in phase space. Biological systems are replete with examples of such driven oscillators in a diverse range of systems including circadian rhythms, neuronal central pattern generators, and the active mechanics of hearing. These biological systems are inherently noisy, and they are typically controlled by active feedback. We explore the fluctuations and response functions of intrinsically noisy limit-cycle oscillators starting with models of stereocilium dynamics in the inner ear. We show that one can obtain a generalized fluctuations-dissipation theorem (GFDT) for the system in a reference frame comoving with the mean dynamical state moving about the limit cycle. However, in the presence of adaptive drives where there is feedback so that the energy input driving the oscillator depends on the state of the system, as in the driven stereocilium, even these generalized fluctuation theorems fail. We further explore the essential role of these feedback mechanisms in breaking GFDTs in noisy driven systems using a combination of simple computational models, analytical calculations, and stereocilium dynamics data.
1:15PM G24.00011: A generalized theory of interactions for complex multiscale stochastic systems with thermodynamic irreversibility*  SANTIAGO NÚÑEZ-CORRALES (Presenter), ERIC JAKOBSSON, University of Illinois at Urbana-Champaign — Understanding nonlinear, hierarchically structured complex systems through the discovery and application of statistical mechanics principles remains a significant challenge. Considering thermodynamic irreversibility is simultaneously essential and often intractable in these cases. Additionally, the presence and filtering of noise across scales often translates into stochastic differential equations for the dynamics, a theoretically and computationally onerous task. We present ongoing work towards a novel mathematical physics development that aims to capture statistical mechanical properties of complex multiscale stochastic systems driven by irreversible thermodynamics, a generalized theory of interactions (GToI) with a purely relational view in which interactions are fundamental entities, while objects and laws are derived. We show how these can be instantiated into concrete theories of interaction (CToIs) capable of capturing key ensemble properties. We exemplify its application to unveiling the underlying complexity of gases and discuss some aspects of its relation to differential models, including relevant computational considerations.

1:27PM G24.00012: Non-equilibrium response of a strongly coupled rotary motor  EMMA LATHOUWERS (Presenter), JOSEPH N. E. LUCERO, DAVID SIVAK, Physics, Simon Fraser Univ — Living systems at the molecular scale are complex (composed of many constituents with strong and heterogeneous interactions), far from equilibrium, and subject to strong fluctuations. This poses significant challenges to efficient, precise, and rapid free energy transduction, yet nature has evolved numerous molecular machines that do just this. Using a simple model of FoF1-ATP synthase (the primary motor for ATP synthesis), we investigate the interplay between non-equilibrium driving forces, natural equilibrium fluctuations, and interactions between the strongly coupled subsystems of this ingenious rotary machine. Additionally, we consider the resulting design principles for effective free energy transduction. Most notably, while one would naively assume that tight coupling between subsystems is preferred, we find that the output power is maximized at intermediate-strength coupling, which permits lubrication by stochastic fluctuations with only minimal slippage.
**1:39PM G24.00013: Stochastic Dynamics and Selection in the One Dimensional Stabilized Kuramoto-Sivashinsky Equation**  
SALONI SAXENA (Presenter), JOHN MICHAEL KOSTERLITZ, Brown University — Many spatially extended nonlinear systems are known to exhibit coarsening - starting from an initial uniform (disordered) state, ordered structures appear, the size of which increases with time. We study coarsening dynamics in the stabilized Kuramoto-Sivashinsky (SKS) equation in one dimension, with and without noise. The SKS equation is used to describe the growth of crystal surfaces, in particular the motion of terrace edges in step-flow growth [1]. The key feature of this equation is that it displays a bifurcation from a uniform steady state to a band of periodic states, depending on the control parameter. Coarsening is studied by analyzing the time evolution of the structure function for a range of control parameter values, starting from a uniform initial state. We find that the width of the structure function decays as a power law with time during an intermediate time regime, until a narrow peak centered at a given wave number is obtained. This is consistent with the emergence of an ordered (periodic) state which grows in spatial extent. We calculate the decay exponents and discuss the influence of the noise amplitude on the values of the exponents. We also make connections with wave number selection.

**1:51PM G24.00014: Maxwell's demons with finite size and response time**  
NATHANIEL RUPPRECHT, DERVIS VURAL (Presenter), University of Notre Dame — Nearly all theoretical analyses of Maxwell's demon focus on its energetic and entropic costs of operation. Here, we focus on its rate of operation. In our model, a demon's rate limitation stems from its finite response time and gate area. We determine the rate limits of mass and energy transfer, as well as entropic reduction for four such demons: those that select particles according to (1) direction, (2) energy, (3) number, and (4) entropy. Last, we determine the optimal gate size for a demon with small, finite response time, and compare our predictions with molecular dynamics simulations with both ideal and nonideal gasses.

402 - Sung Kang, Johns Hopkins University - Tag(s): Focus
11:15AM G25.00001: Inflatable Kirigami Structures*  LISHUAI JIN (Presenter), ANTONIO ELIA FORTE, BOLEI DENG, School of Engineering and Applied Sciences, Harvard University, AHMAD RAFSANJANI, Department of materials, ETH Zürich, KATIA BERTOLDI, School of Engineering and Applied Sciences, Harvard University — Kirigami inspired metamaterials have shown increasing potential in science and engineering due to their ability to achieve large deformations and morphology changes. Here, by embedding a thin kirigami shell into a soft silicon rubber, we present a novel, programmable and inflatable kirigami structure that can deform into a desired shape or trajectory at a given pressure. Moreover, we can easily assemble different actuators together to obtain very complex deformations via a modular design. Sequencing can also be achieved by introducing pressure drops in between the different modules, and feeding a pressure profile as a single input to the actuators. This could potentially benefit future designs for climbing robots and robotic arms, where disposing of multiple outputs given a single input is often necessary. Our study provides a simple, yet powerful strategy to design unprecedented kirigami balloons that will enrich the functionalities of inflatable structures.

11:27AM G25.00002: Capillarity-driven Transformation of Microscopic Cellular Structures  BOLEI DENG (Presenter), SHUCONG LI, KATIA BERTOLDI, JOANNA AIZENBERG, Harvard University — Cellular structures are attracting increasing interest because of their unique mechanical, thermal, electrical, and acoustic properties, which largely depend on their size, shape and topology. As such, systems with tunable functionality can be constructed by tuning the geometry of the structures. Here we report a capillarity-driven transformation on 2D onsite microcellular structures that enables us to change their topology on demand and reversibly. To trigger such transformation both the cellular structure and the material have to be carefully designed, as it requires the formation of capillary menisci upon solvent evaporation at the unit-cell scale as well as the softening and stiffening of the material at the molecular scale. Finally, we show that our strategy can be applied to realize surface with tunable properties including adhesion, friction, hardness, and particle trapping.
Multiscale frequency conversion through input-independent dynamics of bistable lattices*  
MYUNGWON HWANG (Presenter), ANDRES F. ARRIETA, Mechanical Engineering, Purdue university — In this study, we extend the input-independent dynamics to higher-dimensional metastructures. A metabeam is constructed by integrating a bistable lattice along a beam-like outer frame. We obtain frequency response diagrams showing output frequency spectra for each input frequency and observe nonlinear out-of-plane behavior as long as transition waves are triggered along the in-plane bistable lattice direction. Similar to the observations in its one-dimensional counterpart, the transverse output frequencies remain coherent around a single dominant frequency regardless of the input frequency that triggers the transition waves. This result shows transfer of energy between two different length scales – localized in-plane waves and global out-of-plane deflections – and implies that such metabeams display efficient multiscale frequency conversion. Also identified is two qualitatively different routes to frequency conversion depending on the discreteness of the bistable lattice, enabling a greater design freedom. Furthermore, the unit cell design can be easily tuned to alter the metabeam properties, especially in terms of the operating frequency range and output frequency, allowing for a broad range of engineering applications.

Tunable vibro-acoustic metamaterials  
OSAMA BILAL, Univ of Connecticut - Storrs, DAVID BALLAGI (Presenter), LUKAS ULRICH, Mechanical Engineering, ETH Zurich, CHIARA DARAIO, Mechanical and Civil Engineering, California Institute of Technology — Phononic crystals and acoustic metamaterials are architected lattices designed to control the propagation of acoustic or elastic waves. In these materials, the dispersion properties and the energy transfer are controlled by selecting the geometry of the lattices and their constitutive material properties. Most designs, however, only affect one mode of energy propagation, transmitted either as acoustic airborne sound or as elastic structural vibrations. Here, we present a design methodology to attenuate both acoustic and elastic waves simultaneously in all polarizations. We experimentally realize a three-dimensional load-bearing architected lattice, composed of a single material, that responds in a broadband frequency range in all directions and polarizations for airborne sound and elastic vibrations simultaneously. In addition, we show how we can tune the vibro-acoustic response of the metamaterial through external stimuli.
MICHAEL CZAJKOWSKI (Presenter), Georgia Inst of Tech, CORENTIN COULAIS, Institute of Physics, Univ. Amsterdam, MARTIN VAN HECKE, Institute of Physics, Univ. Leiden, ZEB ROCKLIN, Georgia Inst of Tech — Maximally Auxetic behavior, where Poisson’s ratio is the most negative, has been explored and identified in 2D perforated elastic sheets in which rigid square elements are connected at the corners by comparatively flexible elastic “hinges”. While these metamaterials are designed to emulate a uniform zero-energy motion of the free hinge material (mechanism), experiments have revealed qualitatively different non-uniform mechanical response. To understand this, we utilize a coarse graining approach, combined with highly detailed finite element simulations and experiments, to reveal that the perforated elastic sheet mechanics is controlled by a novel set of soft modes that correspond precisely to the well-studied planar Conformal Maps. We exploit this very convenient result to demonstrate new and highly accurate methods of analytically solving for linear and non-linear deformations of real materials. This includes a powerful holographic approach, in which large non-linear deformations may be predictably controlled by simple actuation at the boundary. Finally, we introduce a more general methodology for identifying and controlling the soft modes associated with a broad class of 2D mechanisms including the Miura and Eggbox origami patterns.

PAVEL GALICH (Presenter), EDWIN THOMAS, Rice Univ — Alternating a lossy with a near-lossless material within a structure can lead to remarkable asymmetry in wave propagation. The field of passive (without control of gain and loss by external stimuli) non-Hermitian acoustics is quickly emerging. Here, we propose a simple system comprised of a single pair of lossless (metallic) and lossy (polymeric) resonators in the form of circular ~0.1 mm thin sheets – that demonstrates close to 100% asymmetry in the acoustic reflection coefficient, while at the same time the transmission coefficients are identical. Experimental measurements and theoretical modeling over a wide range of audible frequencies (reflection and transmission coefficients from 1 kHz up to 6.3 kHz) reveal a nearly ideal sonic unidirectional reflector. Such asymmetric acoustic properties are valuable, for example, for concealing objects from sonars, while allowing communication.

12:27PM G25.00007: A universal identity for the Poisson ratios of oblique Miura-ori  
HUSSEIN NASSAR (Presenter), Univ of Missouri - Columbia, ARTHUR LEBÉE, École des Ponts - ParisTech, LAURENT MONASSE, INRIA — Certain origami and origami-like tessellations, such as the Miura-ori and the eggbox pattern, remarkably exhibit equal and opposite in-plane and out-of-plane Poisson ratios. In this talk, we propose and prove a generalization of this identity to all tessellations that can be obtained as the translation surface of one zigzag along another. These include in particular the entire family of oblique, i.e., non-orthotropic, Miura-ori. The proof is based on a perturbative scheme and makes some typical assumptions of rigid folding kinematics; it remains valid for small and large deformations whether the underlying tessellation is symmetrical, developable, flat-foldable, or not.

**12:51PM G25.00009: Toward a microscopic understanding of the dynamics of simple glass-forming liquids**  
* [Invited]  
PATRICK CHARBONNEAU (Presenter), Duke University — The dynamical arrest predicted by mode-coupling theory and the entropy crisis at the random first-order transition are both exact descriptions of simple glass-forming liquids, albeit only in abstract, infinite-dimensional systems. What survives of these features and what other processes come into play in three-dimensional glass formers are questions that remain largely unanswered. In this talk, I present our recent advances toward a microscopic understanding of the finite-dimensional echo of the infinite-dimensional transitions, and of some of the activated processes that affect the dynamical slowdown of simple yet realistic glass formers.

*Simons Foundation Grant No. 454937

**1:27PM G25.00010: Unifying the percolation and mean-field description of the random Lorentz gas**  
PATRICK CHARBONNEAU, Department of Chemistry, Duke University, ERIC CORWIN, Department of Physics, University of Oregon, YI HU (Presenter), Department of Chemistry, Duke University, HARUKUNI IKEDA, FRANCESCO ZAMPONI, Laboratoire de Physique, Ecole Normale Superieure — The random Lorentz gas (RLG) is a minimal off-lattice model of transport in porous media. It is also a minimal model of structural glasses. The exact mean-field, infinite-dimensional limit solution of the RLG indeed predicts a discontinuous dynamical caging transition akin to that of simple liquid glass formers. The RLG, however, is also in the percolation universality class, in which the dynamical caging transition is continuous. These two descriptions are thus fundamentally contradictory. To resolve this paradox, we study the caging regime of the RLG as a function of dimension. We find that the static cage size quantitatively matches the mean-field predictions, and that the percolation transition and the (finite-dimensional echo of the) dynamical transition are clearly distinguishable in all dimensions. As dimension increases, however, the system dynamics grows increasingly controlled by the dynamical transition. In fact, the escape time from the dynamical cage grows exponentially quickly with d, thus resolving the paradox. More significantly, cage escape events are similar to hopping processes, which had mostly eluded theoretical description in standard supercooled liquids.

1:39PM G25.00011: Unveiling the connection between liquid water and its amorphous/glass states  FAUSTO MARTELLI (Presenter), IBM Research UK — Water is unique in many ways. One of the most remarkable peculiarities of water is its polyamorphism, i.e., its capability to acquire more than one amorphous state. The very nature of amorphous ices is still highly debated, but even less is known about their connection to the liquid state. The possibility of a continuous thermodynamic link between the supercooled liquid(s) and the amorphous ices is highly debated. On the other hand, probing such connection is a challenging task, mostly because of the lack of theoretical and/or experimental tools able to account for the high degeneracy of local configurations in statistically isotropic materials.

In this work, we bypass these difficulties by proposing a new strategy that explores structural similarity between the different disordered configurations. We combine GPU-accelerated molecular dynamics simulations with a neural network approach that allows us to clarify the connections between equilibrium liquid water and its amorphous/glass states. Moreover, our results also confirm that liquid water can be interpreted as a two state system, an hypothesis that was always considered at the theoretical level and that is at the heart of water anomalies.

1:51PM G25.00012: Dynamical theory predicted correlation between activated relaxation and thermodynamics in glass-forming liquids  BAICHENG MEI (Presenter), YUXING ZHOU, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — The microscopic Elastically Collective Nonlinear Langevin Equation (ECNLE) theory of glassy dynamics, in conjunction with an a priori mapping of thermal liquids to an effective hard sphere fluid, captures the structural relaxation time of nonpolar molecular liquids over 14 decades. We re-visit this theory for monodisperse hard spheres using the modified-Verlet integral equation theory closure as equilibrium input. Comparison with simulation shows the equation-of-state, static correlation lengths, radial distribution function, and structure factor are remarkably well captured up to very high volume fractions. Numerical ECNLE theory calculations then reveal that the logarithm of the alpha time scales behaves as an inverse power law of the dimensionless compressibility which is a thermodynamic property that quantifies the amplitude of long wavelength density fluctuations. The scaling is linear (cubic) in the low (high) barrier regime, establishing an operational link between glassy relaxation and thermodynamics. The predicted connection is directly tested using solely experimental data, and is well verified for molecular liquids. By introducing one adjustable parameter to capture the low to high barrier crossover, experimental data over 14 decades can be linearized.
How does the character of the Sastry transition depend on the range of interatomic interactions? CAITLIN GISH (Presenter), KAI NAN, ROBERT HOY, Univ of South Florida — The mean pressure $<P_{IS}(\rho)>$ within the inherent structures (IS) of liquids maintained at density $\rho$ and temperature $T >> T_{melt}$ is minimized at the “Sastry” density $\rho_S$. For $\rho < \rho_S$ ($\rho > \rho_S$), these IS are typically cavitated (homogenous). Using molecular dynamics simulations of Mie liquids [$U_n(r) = \varepsilon(r^{2n} - 2r^n)$ with $4 \leq n \leq 12$], we determine how the character of the transition between cavitated and homogeneous IS depends on the range of the interatomic pair potential. We find three principal results: (i) As $n$ increases with $T$ held fixed, $\rho_S$ approaches and then exceeds the crystallization density $\rho_X$; (ii) as a consequence, the portion of systems’ phase diagrams (in terms of $P$ and $T$) where systems are liquids with predominantly cavitated IS decreases with increasing $n$; (iii) For $\rho > \rho_S$, the pair correlation functions $g(r)$ of the liquids’ IS are nearly conformal, i.e. the $g(r)$ for different $n$ nearly map to a common reduced pair correlation function $G(\rho^{1/3}r) = \rho^{-1/3}g(r)$. We discuss the implications of these results for condensation and cavitation of simple atomic liquids.

Investigation into the dynamics of lipid membrane remodeling
ABHIMANYU SHARMA (Presenter), Physics & Astronomy, University of Utah, HENRY NGUYEN, NATHANIEL TALLEDGE, Biochemistry & Biophysics, University of California San Francisco, JOHN MCCULLOUGH, Biochemistry, University of Utah, FRANK MOSS III, Biochemistry & Biophysics, University of California San Francisco, JANET IWASA, Biochemistry, University of Utah, MICHAEL VERSHININ, Physics & Astronomy, University of Utah, WESLEY SUNDQUIST, Biochemistry, University of Utah, ADAM FROST, Biochemistry & Biophysics, University of California San Francisco — Lipid membranes play a key role in biology, enclosing entire living cells, as well as intracellular compartments. Cellular processes such as endocytosis, virus budding, and cytokinesis involve changes in membrane shape and connectivity. Membrane remodeling is essential, common, and tightly regulated. A variety of pathways, including the endosomal sorting complexes required for transport (ESCRT) machinery are involved in locally changing membrane curvature (both invagination and evagination), tabulation, and scission. However, the mechanics of many of these remodeling events are still poorly understood. We have used an in vitro GUV system, and investigated the details of membrane reshaping under local mechanical load and in several ESCRT protein backgrounds. We will discuss our results, which demonstrate how protein-based regulation can help remodel bilayer membranes.
**11:27AM G26.00002: Investigating cell shape changes during organogenesis using a 3D vertex model**

PAULA SANEMATSU (Presenter), Department of Physics, Syracuse University, GONCA ERDEMCI-TANDOGAN, Institute of Biomaterials and Biomedical Engineering, University of Toronto, MATTHIAS MERKEL, Alan Turing Centre for Living Systems and Centre de Physique Théorique, Aix-Marseille University, JEFFREY D. AMACK, Department of Cell and Developmental Biology, State University of New York, Upstate Medical University, M. LISA MANNING, Department of Physics, Syracuse University

— Left-right (LR) asymmetry present in internal organs of vertebrates initiates during embryonic development with observable changes to individual cell shapes which are vital to the creation of functional organs. However, the mechanisms that drive cell shape changes remain poorly understood. Kupffer's vesicle (KV) is a transient organ in the Zebrafish embryo that acts as the LR organizer. As the KV moves through the surrounding tissue during development, KV cells change shape along the anterior-posterior (AP) axis, a necessary process for subsequent LR asymmetry[1]. Erdemci-Tandogan et al.[2] used a 2D vertex model and experimental data to show that surrounding tissue rheology and KV cell motility could drive KV cell shape changes. Since the KV is inherently 3D, and that 2D and 3D drag forces can be very different, we extend that work by studying drag forces on the KV in a 3D model. We show that cell shape changes along the AP axis do occur in 3D due to drag forces. By implementing particle-image-velocimetry (PIV) analysis, we quantitatively compare simulation and experimental data of the flow of surrounding cells past the KV as it develops.

SAMIRA ANBARI (Presenter), JAVIER BUCETA FERNANDEZ, Chemical and Biomolecular Engineering, Lehigh Univ — Within the topic of morphogenesis, tissue elongation is a necessary process in all metazoans to shape their body plans which is not fully understood. For example, in the particular case of the limb, it has been shown that tissue elongation cannot be explained by either a localized proliferation of cells or their oriented divisions and, surprisingly, the tissue elongates perpendicular to the direction along which cell grow. Here we propose a mechanism of tissue elongation that couples the mechanical properties of cells with the concept of positional information to modulate the former in a location-dependent manner. To illustrate our proposal, we use morphogen gradient thresholds as well as Turing patterning system as the mean used by cells to “know” their relative positions within a primordium. Our numerical simulations are based on the vertex model system and we show that if the cell-cell adhesion is modulated as a function of the location of cells within a primordium, an auto-catalytic cell intercalation process develops and the tissue elongates. Moreover, our results reveal that cells grow perpendicular to the elongation direction as experimentally reported. Altogether, our results shed light on the tissue elongation problem and pave the way to better understand morphogenesis.
11:51AM G26.00004: Morphogenesis and fractal dimension of bacterial pellicles  BOYANG QIN (Presenter), NED WINGREEN, BONNIE BASSLER, HOWARD A STONE, Princeton University — Bacteria cells can self-organize into structured communities at phase boundaries, known as biofilms. At liquid-liquid and liquid-air interfaces, these soft, living materials of cells and extracellular polysaccharides – called pellicles – confer survival advantages and protection against environmental insults to the community. These benefits are not attainable by individual planktonic cells. The mechanics driving pellicle formation and morphology are not understood. Here, using a home-made adaptive stereoscope instrument and fluorescent microscopy, we identify a series of mechanical and architectural transitions in *Vibrio cholerae* pellicles at a liquid-oil interface. There are three distinct stages: emergence of founding colonies, onset of primary and secondary wrinkling instabilities, and a fractal-order increase in complexity. We show that although cells in a pellicle share a habitat, founder colonies remain monoclonal, hence the community maintains spatial and genetic heterogeneity.

12:03PM G26.00005: Learning about human development from clinical IVF data  BRIAN LEAHY (Presenter), HELEN YANG, WON-DONG JANG, Harvard University, DALIT BEN-YOSEF, Lis Maternity Hospital, VINOTHAN MANOHARAN, DANIEL NEEDLEMAN, Harvard University — The early human embryo is the physicist’s dream for studying development. Between fertilization and implantation in the uterus, mammalian embryos undergo a global reorganization (compaction) followed by a symmetry-breaking differentiation (blastocyst formation), with no external direction from the mother. But for ethical reasons, we cannot do experiments with human embryos. So how can we understand human development without experiments? Here, we examine tens of thousands of videos of human embryos recorded during routine clinical IVF procedures. We use those videos to explore the natural variability in mammalian preimplantation embryo development, and we leverage this variability to identify critical factors in early development.
Emergence of helical growth and morphogenesis in fungal cells from cell wall dynamics*

SHANKAR LALITHA SRIDHAR (Presenter), GUILLAUME LOSTEC, Mechanical Engineering, University of Colorado, Boulder, JOSEPH K.E. ORTEGA, Mechanical Engineering (Emeritus), University of Colorado Denver, FRANCK J. VERNEREY, Mechanical Engineering, University of Colorado, Boulder — Walled cells such as plants, algae and fungi achieve expansive growth using turgor pressure that helps mediate irreversible wall deformation and regulates their shape and volume. The architecture of the cell wall plays a crucial role in this process where a network of microfibrils and tethers (complex polysaccharides and proteins) dynamically mediate the network topology via continuous detachment and reattachment events. The growth of Phycomyces blakesleeanus, a wiry single-celled sporangiophore that typically grows longitudinally, is particularly intriguing as it also rotates (clockwise from top) indicating helical growth. There is no apparent functional purpose for this rotation which has led to speculation that it is a direct consequence of wall architecture, and specifically a microfibril re-orientation mechanism. Interestingly, in piloboloid mutants longitudinal growth is combined with radial growth to produce a rotation inversion, i.e. anti-clockwise rotation. In this talk, we will present a novel approach based in statistical mechanics to model the organization and dynamics of microfibrils and tethers in the cell wall of to help explain this phenomenon.

Understanding cell contact constriction in epithelial morphogenesis through data driven reverse-time inference

NICOLAS LENNER (Presenter), Max Planck Institute for Dynamics and Self-Organization, DEQING KONG, Faculty of Medizin, University of Göttingen, STEPHAN EULE, Max Planck Institute for Dynamics and Self-Organization, JÖRG GROSSHANS, Faculty of Medizin, University of Göttingen, FRED WOLF, Max Planck Institute for Dynamics and Self-Organization — Tissue elongation via convergent extension mediated by cell intercalation is a frequent mechanism in the development of metazoans. During Drosophila germband extension cell intercalation is achieved by acto-myosin driven junction shrinkage of neighboring cells, its resolution into a vertex of four neighboring cells, and subsequent junction formation in orthogonal direction. Despite tremendous progress in the understanding of the molecular underpinnings involved in this process called a T1 transition, a quantitatively tested mechanism that predicts the dynamics of individual cell-junctions is still not available. We here show how our mathematically novel approach of reverse time ensemble inference allows to infer the process of junction shrinkage in reverse time, starting from the endpoint of the dynamic, i.e. the 4-vertex. We apply our inference scheme to ~1000 T1 transitions and systematically rule out model classes of increasing complexity using all accessible ensemble statistics. We find visco-elastic like dynamics, infer the onset of each individual junction collapse and link the inferred junctional dynamics to the simultaneously recorded myosin dynamics.
12:39PM G26.00008: Experiments and modeling of “irreversible” brain torsion in early chick embryos*  ZI CHEN (Presenter), HAO ZHANG, GUANGCHAO WAN, Thayer School of Engineering, Dartmouth College, WEI ZENG, University of Virginia, HANNAH GROVER, SHICHENG HUANG, Thayer School of Engineering, Dartmouth College — The rightward torsion of the chick embryonic brain tube is one of the earliest organ-level left-right asymmetry developmental events, often associated with birth defects such as situs inversus, but the biomechanics of this process remains incompletely understood. Previous works showed that vitelline membrane (VM) exerts a force on the brain that drives the torsion, and surface tension (ST) can replace the mechanical role of VM. However, our experiments showed when ST was removed the torsion does not fully reverse suggesting other overlooked mechanical factors. Here, we use a combination of experiments and modeling to reveal that the deformation during the early brain torsion can be path and stage dependent. With optical coherence tomography imaging, we tracked the twisting and untwisting in a step-wise manner. A computational model is employed to help interpret the findings, in particular the path-dependent, "irreversible" shape evolution. Results show that the body forces such as gravity and buoyancy also play an important role during this left-right asymmetric morphogenesis process, thus revealing the hidden mechanical factors in the normal and abnormal development of early embryos.

12:51PM G26.00009: Dynamics of a single cell fate decision*  SIMON FREEDMAN (Presenter), KRISTIN JOHNSON, CAROLE LABONNE, MADHAV MANI, Northwestern University — As an animal develops from a fertilized egg into a complex multicellular organism, its cells change from being pluripotent to lineage restricted. These state changes are often driven by morphogens, molecules that launch signalling cascades that affect DNA transcription and modify a cell's protein makeup. While morphogens and cell fates have been extensively identified, the process through which a morphogen changes a cell's fate is not well understood. To elucidate these dynamics, we performed bulk RNA sequencing at multiple time points during a single cell fate decision in which pluripotent Xenopus laevis (African frog) cells differentiate to one of two fates: neural progenitor and epidermis. We found that the geometric structure of both transitions include linear temporal trends that correspond with development toward a neural fate, and that epidermal fated cells exhibit a second, non-linear temporal trend that corresponds with BMP activation. Our analyses enabled us to predict a point-of-no-return for the epidermal fate, which we experimentally verified. Our work highlights the importance of examining intermediate developmental times to discern fate specification, and sheds light on distinguishing the internal and external forces that drive embryonic development.

1:03PM G26.00010: Binary establishment and maintenance of discrete cell fates in development  JIAXI ZHAO (Presenter), Department of Physics, University of California, Berkeley, JACQUES BOTHMA, MATTHEW NORSTAD, HERNAN G. GARCIA, Department of Molecular and Cell Biology, University of California, Berkeley — During embryonic development, cells must ultimately adopt discrete fates. Positive autoregulation has been proposed as a general mechanism for establishing and maintaining these discrete cell-fate decisions. Here, we quantitatively dissect the role of autoregulation and bistability in establishing binary cellular fates in the fruit fly Drosophila melanogaster. Specifically, we apply recently developed single-cell live imaging techniques to quantify transcriptional and protein dynamics of the Drosophila pair-rule gene fushi tarazu as cells decide whether to commit to the expression of the gene.

1:15PM G26.00011: A variational principle for power dissipation in low frequency conduction in biological tissues.  FRANCISCO SOLIS (Presenter), School of Mathematical and Natural Sciences, Arizona State University, VIKRAM JADHAO, Intelligent Systems Engineering, Indiana University Bloomington — Propagation of low-frequency electrical signals in biological tissues appears naturally in neural and cardiac physiological systems. These signals can also be externally applied to tissues as part of experimental probes or therapeutic tools. Models for propagation of these signals usually consider tissues as purely conductive materials. In large systems such as whole bodies or organs, these models consider the systems as composed of finite domains of homogeneous regions with distinct conductivities. The electric fields in these model systems exhibiting piecewise-uniform conductivity obey equations similar to those of electrostatics in polarizable media, but with boundary conditions set by current conservation. In this presentation we show that the electric fields can be obtained via a variational principle based on the minimization of dissipated power. In addition to providing a conceptual framework to the problem, this principle allows the construction of approximate solutions. It can also be used to establish bounds on the spectrum of the integral and differential operators that appear naturally in these problems.

1:27PM G26.00012: A biophysical model uncovers the size distribution of migrating cell clusters across cancer types  FEDERICO BOCCI (Presenter), Center for Theoretical Biological Physics, Rice University, MOHIT KUMAR JOLLY, Indian Institute of Technology, JOSE N ONUCHIC, Center for Theoretical Biological Physics, Rice University — Migration from the primary tumor is a crucial step in the metastatic cascade. Cells with various degrees of adhesion and motility migrate into the bloodstream as single circulating tumor cells (CTCs) or multi-cellular CTC clusters. The frequency and size distributions of these clusters have been recently measured, but the underlying mechanisms enabling these different modes of migration remain poorly understood. We present a biophysical model that couples intra-tumoral heterogeneity enabled by the epithelial-mesenchymal transition (EMT) with cell migration to explain the modes of individual and collective cancer cell migration. This reduced physical model undergoes a transition from individual migration to collective cell migration and robustly recapitulates CTC cluster fractions and size distributions observed experimentally across several cancer types, thus suggesting the existence of common features in the mechanisms underlying cancer cell migration. Overall, this biophysical model provides a platform to continue to bridge the gap between the molecular and biophysical regulation of cancer cell migration, and highlights that a complete EMT might not be required for metastasis.
1:39PM G26.00013: Spatial Distribution of Immune Cells in Tumors*  

JULIANA C. WORTMAN (Presenter), Department of Physics and Astronomy, University of California, Irvine, TING-FANG HE, SHAWN SOLOMON, ROBERT ZHANG, ANTHONY ROSARIO, ROGER WANG, TRAVIS Y. TU, Department of Immuno-Oncology, City of Hope Comprehensive Cancer Center, DANIEL SCHMOLZE, Department of Pathology, City of Hope Comprehensive Cancer Center, YUAN YUAN, SUSAN E. YOST, Department of Medical Oncology and Therapeutics Research, City of Hope Comprehensive Cancer Center, XUEFEI LI, HERBERT LEVINE, Department of Bioengineering, Rice University, GURINDER ATWAL, Cold Spring Harbor Laboratory, PETER P. LEE, Department of Immuno-Oncology, City of Hope Comprehensive Cancer Center, CLARE YU, Department of Physics and Astronomy, University of California, Irvine — The goal of immunotherapy is to enhance the ability of the immune system to kill cancer cells. Immunotherapy is more effective and, in general, the prognosis is better, when more immune cells infiltrate the tumor. We describe various techniques we have developed to explore the question of whether the spatial distribution rather than just the density of immune cells in the tumor is important in forecasting whether cancer recurs. We apply our approach to immune cells in images of tumor tissue taken from (triple negative) breast cancer patients. We find that there is a distinct difference in the spatial distribution of immune cells between good clinical outcome (no recurrence of cancer within at least 5 years of diagnosis) and poor clinical outcome (recurrence within 3 years of diagnosis).

1:51PM G26.00014: Computationally tractable mechanistic model of inhomogeneous -- anisotropic drug diffusion and tumor ablation  

ERDI KARA (Presenter), AMINUR RAHMAN, EUGENIO AULISA, Mathematics and Statistics, Texas Tech Univ, SOUPARNO GHOSH, Statistics, University of Nebraska–Lincoln — In this work, we study the effect of drug distribution on tumor cell death when the drug is internally injected in the tumorous tissue. We derive a full 3-dimensional inhomogeneous – anisotropic diffusion model. To capture the anisotropic nature of the diffusion process in the model, we use an MRI data of a 35-year old patient diagnosed with Glioblastoma multiform (GBM) which is the most common and most aggressive primary brain tumor. After preprocessing the data with a medical image processing software, we employ finite element method in MPI-based parallel setting to numerically simulate the full model and produce dose-response curves. We then illustrate the apoptosis (cell death) fractions in the tumor region over the course of simulation and proposed several ways to improve the drug efficacy. Our model also allows us to visually examine the toxicity. Since the model is built directly on the top of a patient-specific data, we hope that this study will contribute to the individualized cancer treatment efforts from a computational bio-mechanics viewpoint.
A possible role for epigenetic feedback regulation in the dynamics of the epithelial-mesenchymal transition (EMT)\footnote{This research is supported by Physics Frontiers Center NSF Grant PHY-1427654 (WJ and HL); NSF Grant PHY-1605817 (WJ, AD, SM and HL); NIH,R01CA200970 (SM) and 2R01CA155243-06A1 (AD and SM). MKJ is supported by Ramanujan Fellowship awarded by SERB, DST, Government of India (SB/S2/ Rjn-049/2018).}

WEN JIA (Presenter), Rice Univ, ABHIJEET DESHMUKH, SENDURAI A MANI, MD Anderson Cancer Center, MOHIT KUMAR JOLLY, Indian Institute of Science, HERBERT LEVINE, Rice Univ — Epithelial-mesenchymal transition (EMT) plays an important role in cancer metastasis and drug resistance, and involves epigenetic remodeling. However, how epigenetic changes affecting the dynamical traits such as plasticity or memory are not fully understood. Here, we analyzed the effects of epigenetic feedback on EMT through integrating this feedback on various aspects of the miR-200/ZEB loop – a core circuit regulating EMT. Epigenetic feedback on self-activation of ZEB has minor effects in population distribution and transition times, but epigenetic feedback on the inhibition of miR-200 by ZEB can largely stabilize the mesenchymal state, thus making the process irreversible. Follow-up preliminary experiments show that when EMT is induced in epithelial cells, a certain percentage of cells can stay in mesenchymal state after the inducing signal is removed. This percentage depends on the extent of induction of EMT, thus well recapitulating our model-based predictions.

Tuesday, March 3, 2020 11:15 AM - 2:15 PM

Session G27 FIAP: Electronic Structure: Thermodynamic & Optical Properties

11:15AM G27.00001: Carrier Lifetime and Mobility in GaAsNBi Alloys\footnote{We gratefully acknowledge support from the National Science Foundation (Grant Nos. DMR 1410282, DMR 1810280 and DMR 0959341)}

BRENNAN ARNOLD, JAMES HEYMAN (Presenter), Physics, Macalester Coll, ANDRA CHEN, JARED MITCHELL, RACHEL GOLDMAN, Materials Science Engineering, University of Michigan — III-V alloys incorporating Nitrogen and Bismuth are of significant interest for optoelectronic applications in the near- and mid-infrared. We report measurements of the photoconductivity lifetime and photocarrier mobility in a series of GaAs\(_{1-x-y}\)N\(_x\)Bi\(_y\) samples grown on GaAs by MBE. We find short conductivity lifetimes of order 3ps to 5ps and carrier mobilities of order 30 to 80cm\(^2\)/Vs. Time-resolved photoconductivity was obtained from optical pump, THz probe measurements, and steps were taken to avoid the influence of the GaAs substrate: A tunable optical pump permitted excitation below the GaAs bandgap, and transient THz reflection was used as a surface-specific probe of the conductivity. The short carrier lifetime and low carrier mobility likely arises due to rapid carrier trapping in these materials.
11:27AM G27.00002: Study of \( \beta\text{-Ga}_2\text{O}_3 \) Photoluminescence with Above Bandgap Laser Excitation

JEFFREY LAPP (Presenter), DINESH T THAPA, Univ of Idaho, JESSE HUSO, Klar Scientific, AMRAH CANUL, Univ of Idaho, MATTHEW MCCLUSKEY, Washington State University, LEAH BERGMAN, Univ of Idaho — \( \beta\text{-Ga}_2\text{O}_3 \) is being considered as a next generation ultra-wide bandgap semiconductor with promising UV device applications. \( \beta\text{-Ga}_2\text{O}_3 \) films were grown via RF sputtering and photoluminescence (PL) was performed using 5.1 eV laser excitation, which is above the predicted bandgap of \( \sim 4.9\text{eV} \). Weak UV PL was detected at 4.85eV and 4.20eV. The near band edge (NBE) PL at 4.85eV is consistent with subsequent transmission measurements of the films that showed a bandedge value of 4.85eV. Due to the strong trapping affinity of holes in \( \text{Ga}_2\text{O}_3 \) previously predicted by theory, observation of NBE PL at 4.85eV PL has been deemed unlikely. We speculate that the laser intensity employed in our experiments was sufficient to create a small density of free holes enabling NBE in \( \text{Ga}_2\text{O}_3 \). The 4.20eV PL emission exhibits peak shifts up to \( \sim 100\text{meV} \) under different annealing environments. Strong UV emissions were also observed at 3.14eV and 3.56eV, which have been attributed to donor-acceptor recombination and self-trapped holes, respectively. Emission due to self-trapped holes was not detected when sub-bandgap laser excitation of 3.8eV was utilized.

11:39AM G27.00003: Optical properties of GaN/Er:GaN/GaN core-cladding planar waveguides

YAQIONG YAN (Presenter), ZHENYU SUN, TREY BRENDBAN SMITH, WEIPING ZHAO, JING LI, JINGYU LIN, HONGXING JIANG, Texas Tech University — Erbium doped GaN (Er:GaN) is a promising candidate as a gain medium for high energy lasers (HELs) operating at the “retina-safe” spectral region around 1.5 \( \mu\text{m} \) due to outstanding thermal, mechanical and optical properties of GaN host. Compared to YAG, GaN has a much higher thermal conductivity of \( k \approx 253 \text{ W/m*K} \) and a smaller thermal expansion coefficient of \( \alpha \approx 3.53 \times 10^{-6} \text{ °C}^{-1} \) and the potential to significantly outperform YAG based HELs. We report here the successful fabrication and optical characterization of GaN/Er:GaN/GaN core-cladding planar waveguides (PWGs). Optical confinement in the core layer has been investigated. The measured optical loss coefficients of Er:GaN PWGs at 1.54 \( \mu\text{m} \) have been measured and are respectively 1.0 \( \text{cm}^{-1} \) for the transverse electric (TE) and 1.2 \( \text{cm}^{-1} \) for the transverse magnetic (TM) modes. Approaches to further reduce the optical loss and optimal configuration for resonantly pump GaN/Er:GaN/GaN PWGs for achieving amplification near 1.5 \( \mu\text{m} \) have been identified.

*The work is supported by the Directed Energy – Joint Transition Office Multidisciplinary Research Initiative program (grant #N00014-17-1-2531). H. X. Jiang and J. Y. Lin would also like to acknowledge the support of Whitacre Endowed Chairs by the AT & T Foundation.
**11:51AM G27.00004: Optical properties of indium tin oxide thin-films at high temperature**

JIWOONG KIM (Presenter), Department of Physics, Pusan National University, SUJAN SHRESTHA, MARYAM SOURI, JOHN G CONNELL, Department of Physics and Astronomy, University of Kentucky, SUNGYUN PARK, Department of Physics, Pusan National University, AMBROSE SEO, Department of Physics and Astronomy, University of Kentucky — Indium tin oxide (ITO) is one of the most widely used transparent conductors. However, its high-temperature optical properties, which are important for device applications in extreme conditions such as space missions, have not been studied. We have investigated the optical properties of ITO thin-films up to 800 °C using *in situ* optical spectroscopic ellipsometry equipped within a vacuum chamber. The amorphous ITO films show an abrupt change of optical constants at 300 °C due to crystallization. Above 400 °C, the bandgap energy of the ITO thin-film decreases with increasing temperature, implying that electron-phonon interaction broadens the interband optical transitions. The reduction of bandgap energies due to electron-phonon interaction is also observed in epitaxial ITO thin-films. Nevertheless, both amorphous and epitaxial ITO thin-films remain optically transparent even at high temperatures up to 800 °C. In addition, background gas environments reversibly alter the bandgap energies of the epitaxial ITO thin-films, suggesting that the diffusion of oxygen vacancies occurs vigorously.

**12:03PM G27.00005: On the Thermo-Optical Interactions at the Band-Edge in ZnO Thin Films**

AMRAH CANUL (Presenter), DINESH T THAPA, JEFFREY LAPP, Univ of Idaho, GRANT NORTON, Washington State University, LEAH BERGMAN, Univ of Idaho — The study of the band edge in UV-Vis absorption spectra has impacted fundamental understanding of semiconductor physics as well as advances in technological application. An analytical approach based on the derivative of the absorption spectra was used to explore the nature of the near band edge (NBE) of ZnO thin films grown via the sputtering technique. It was found that the NBE is composed of a Gaussian where the width and peak position were employed to model the electron-phonon (e-p) interaction and defect characteristics of the film. These characteristics were studied via transmission experiments in the temperature range of 77 K to 532 K. The as-grown film was found to exhibit a very weak e-p coupling relative to the static contribution of defects. Upon successive controlled annealing of the ZnO film, up to 800 °C, the defect component diminished and the phonon contribution became dominant. X-ray diffraction and imaging studies agree with these results. The defects in the ZnO films are discussed in terms of structural inhomogeneities and Zn interstitials which are prevalent in ZnO films grown via sputtering.

12:15PM G27.00006: Comparison of ZnO Nanoparticles Synthesized by Microwave-assisted and Precipitation Method*  RUSIRI RATHNASEKARA (Presenter), HARI PARAMESWAR, Univ of Tulsa — In this work, Zinc Oxide (ZnO) Nanoparticles were synthesized using precipitation and microwave methods with different pH values (8, 9, and 10). Structural properties were studied by means of Transmission Electron Microscopy (TEM), X-ray Diffraction Spectroscopy (XRD), Impedance Spectroscopy, and Optical Spectroscopy. TEM images revealed that the morphology of nanoparticles increased from 8 nm to 16 nm synthesized by precipitation method while the diameter increased from 9 nm to 15 nm in microwave assisted method. The XRD confirmed the wurtzite structure in all samples with no secondary phases. Optical properties were studied by means of Photoluminescence (PL) and absorption measurement. Band gap of nanoparticles were also calculated and found to decrease from 3.25 eV to 3.18 eV in ZnO particles prepared by the precipitation method, whereas bandgap decreases from 3.21 eV to 3.19 eV in the microwave method. Electrical transport properties of nanoparticles were analyzed by impedance spectroscopy using Cole-Cole plot technique. From Impedance spectra, we observe that resistance and capacitance of nanoparticles depend on the size of nanoparticles synthesized by both precipitation and microwave method.

12:27PM G27.00007: Realizing GaN/Er:GaN/GaN core-cladding planar waveguide gain medium via hydride vapor phase epitaxy*  ZHENYU SUN (Presenter), YAQIONG YAN, TREY BRENDAN SMITH, WEIPING ZHAO, JING LI, JINGYU LIN, HONGXING JIANG, Texas Tech Univ — Erbium doped gallium nitride (Er:GaN) bulk crystals have been identified as a promising optical gain material for solid-state high energy lasers (HELs) operating at the 1.5 mm “retina-safe” spectral region. A highly desired design of HEL gain medium is the core-cladding planar waveguide (PWG) structure, capable of providing excellent heat dissipation and optical confinement. We report the realization of a GaN/Er:GaN/GaN core-cladding PWG structure grown by hydride vapor phase epitaxy (HVPE) and processed by mechanical and chemical-mechanical polishing. An Er doping concentration of [Er] = 3 × 10^{19} \text{ atoms/cm}^3 has been confirmed in the core layer via secondary ion mass spectrometry measurements. The structure emitted strong 1.54 \mu m emission under 980 nm resonant excitation. It was shown that a 96% optical confinement can be achieved in the Er:GaN core layer with a core thickness of 50 \mu m and [Er] = 3 \times 10^{19} \text{ atoms/cm}^3. This work paves the way and marks an important progress towards the practical application of Er:GaN gain medium for “retina-safe” HELs.

*The work is supported by the Directed Energy – Joint Transition Office MRI program and ONR (grant # N00014-17-1-2531). H. X. Jiang and J. Y. Lin would like to acknowledge the support of Whitacre Endowed Chairs by the AT & T Foundation.
12:39PM G27.00008: Two-photon absorption spectroscopy and anisotropy of bulk zincblende and diamond symmetry semiconductors and quantum dots*  BRANDON FUREY (Presenter), University of Texas at Austin, RODRIGO MISAEL BARBA-BARBA, ALAN BERNAL, Centro de Investigaciones en Optica, TUSHTI SHAH, BRIAN KORGEL, University of Texas at Austin, RAMON CARRILES, BERNARDO MENDOZA SANTOYO, Centro de Investigaciones en Optica, MICHAEL C DOWNER, University of Texas at Austin — Si quantum dots (SiQD) are potential candidates for biologically-inert theranostic applications. Excitation in the red-near infrared (NIR) by two-photon absorption (2PA) is useful for confocal microscopy and therapy techniques. We studied the spectroscopic response and size-dependence of 2PA in colloidal ligand-passivated SiQDs in the red-NIR by indirect two-photon induced photoluminescence (2PIP) and direct pump-probe modulation spectroscopy (PPMS). We are developing a model to explain the spectra for the nanocrystalline response from ab initio calculations using length gauge theory for bulk Si. We measured the 2PA spectra and anisotropies of bulk Si, GaAs, and GaP in the range 650-2000 nm using PPMS in the femtosecond excitation regime to further verify these calculations.

12:51PM G27.00009: Scanning Photocurrent Measurements of Degenerately Doped Si*  MAARTEN DE HAAN (Presenter), TIANHAN LIU, XI WANG, HANWEI GAO, PENG XIONG, Florida State Univ — Scanning photocurrent microscopy (SPCM) has shown much promise as a means for direct and efficient measurements of carrier lifetime and diffusion in novel semiconductors including topological insulators. High spatial resolution and electrical sensitivity in these setups has made detection of properties such as diffusion length routine. Degenerately doped Si with a surface oxide are often used as back-gating substrates for thin films or flakes of the materials. However, the high photocurrent of the silicon often complicates the elucidation of the same photo responses in thin films/flakes. Here, we present SPCM measurements of a degenerately doped silicon substrate. After buffered HF etching of the surface oxide, Cr/Au electrodes were defined via thermal evaporation through a shadow mask, resulting in a device of 25 μm channel width between two back-to-back Schottky contacts. An elevated photocurrent was measured in the regions near the electrodes at zero bias voltage, indicating a diffusion current. The experiment has shown the structure as a viable platform for SPCM measurements of thin topological insulators under continuous backgate tuning.

*Work supported by NSF grant DMR-1905843
Temperature dependence of the indirect-gap photoluminescence from Ge

JOSE MENENDEZ, CHRISTIAN POWELEIT, SEAN TILTON (Presenter), Arizona State Univ — Few experimental reports have been published to date on the temperature dependence of the photoluminescence (PL) from Ge, and no attempts have been made to model the spectra using the standard Van Rosbroeck-Schockley equation that relates absorption to spontaneous emission. This anomaly can be traced back to the fact that the standard textbook expressions for indirect absorption are not applicable to Ge due to the proximity of the direct and indirect gaps. If such expressions are used to compute the PL, not even a peak is predicted.

We report here a PL study of high-quality Ge samples at temperatures $10 \, \text{K} \leq T \leq 300 \, \text{K}$. The spectra display a rich structure with a rapidly changing lineshape as a function of $T$. We show that when the more realistic theory of LA-phonon assisted absorption from Ref. 1 is used to compute the PL, peaks at about the right energy are predicted. However, the agreement between theory and experiment requires the additional incorporation of “forbidden” channels involving LO and TA phonons. Analytical expressions for the absorption assisted by these phonons are derived, and the resulting expressions are combined to predict a PL spectrum in very good agreement with experiment.

First-principles calculation of Jerk current in polar and nonpolar semiconductors

BERNARDO MENDOZA SANTOYO, Centro de Investigaciones en Optica, A.C., BENJAMIN FREGOSO, SUMAN PANDAY (Presenter), Kent State Univ - Kent — The bulk photovoltaic effect is the archetypical example of nontrivial carrier dynamics in illuminated insulators lacking a center of inversion. The injection current (also known as ballistic current or circular photogalvanic effect), a component of the bulk photovoltaic effect, could play an important role in optoelectronic applications, e.g. solar cells or as a probe of the topology of materials. The Jerk current is a generalization of the injection current to third order in the electric fields [1]. We present a first-principles calculation of the Jerk current spectrum in prototypical semiconductors Si, CdSe, GaAs and novel two-dimensional ferroelectric monolayer GeSe, GeS, SnS and SnSe. We show that, similar to the injection current, the jerk current is a sensitive probe of the geometry of the Bloch wave specially in reduced dimensions. Experimental ramifications are also discussed.

1:27PM G27.00012: Exploration of Free Carrier Relaxation Dynamics in Bulk Gallium Arsenide
ADAM HALAOUI (Presenter), GEOFFREY DIEDERICH, MARK SIEMENS, Univ of Denver — Multidimensional coherent spectroscopy (MDCS) is an ultrafast spectroscopic measurement that spreads coherent information across multiple dimensions, disentangling congested spectral features. Both coherent and incoherent transport processes, as well as their dynamics, can be easily separated and measured with MDCS. These attributes make MDCS ideal for studying complex material behaviors such as carrier-carrier scattering and exciton formation in semiconductors.

Here, we present MDCS spectra of bulk gallium arsenide (GaAs) showing strain-induced separation of the heavy-hole and light-hole exciton states\(^1\), exciton formation from free carriers across a broad energy distribution, and relaxation from GaAs quantum wells in the same sample. The spectra clearly show the Sommerfeld enhancement of the free carrier absorption at long times, while early times show a transient feature related to the fast relaxation of states near the band-edge. We suspect that this transient feature is caused by correlated free carrier pairs or higher-lying excitonic states that form a quasi-continuum near the band edge.

*We acknowledge the financial support of the National Science Foundation

1:39PM G27.00013: Evaluation of BaTiS\(_3\) for Thermoelectric Applications by Using First Principles Theory
TULA PAUDEL (Presenter), EVGENY Y TSYMBAL, University of Nebraska - Lincoln — BaTiS\(_3\) is a semiconductor with a band gap of about 0.5 eV and very strong transport anisotropy for both electron and hole conduction. The conduction band minimum is very dispersive with a small effective mass and large mobility because of split-off \(dz^2\) band contribution. The optical phonons are relatively soft, and the ground state non-centrosymmetric phase is favorable by just about 1 mev/fu over the centrosymmetric phase, indicating possibility of phase intermixing and reduced thermal conductivity at finite temperatures. Electrons can be doped easily for instance by an external dopant La. The possibility of large electrical conductivity with a tunable thermal conductivity by external doping and phase intermixing makes this compound excellent candidate for thermoelectric applications. By using the first principles density functional theory and linearized Boltzmann transport theory, we calculate electrical conductivity, thermal conductivity and the Seebeck coefficient and report reasonable thermoelectric figure of merit, ZT, of about 0.4 at 800K for n-type BaTiS\(_3\). Additional possibility to enhance the figure of merit by doping, phase intermixing and band engineering is discussed.
1:51PM G27.00014: First Principles Study of Electronic, Magnetic and Thermoelectric Properties of Perovskite BaTbO$_3$

DHURBA JAISHI (Presenter), Central Department of Physics, Tribhuvan University, DINESH KUMAR YADAV, Condensed Matter Physics Research Center, Butwal-11, Rupandehi, Nepal, MADHAV PRASAD GHIMIRE, Central Department of Physics, Tribhuvan University — Perovskite material have been on focus for many applications in spintronic device due to their novel properties such as ferroelectric, metal-insulator-transition, half-metallicity, non-trivial topological properties, etc. Recently these materials are found to show interesting thermoelectric properties which are expected to lead to new devices to harvest waste heat into efficient energy. In this work, we have investigated the electronic, magnetic, and thermoelectric properties of BaTbO$_3$ using the density functional formalism. The structure are fully relaxed and the value of the calculated lattice constant is 4.29 Å, in good agreement with the experimental values. The magnetic ground state of BaTbO$_3$ is found to be G-type antiferromagnet, with a band gap of 1.68 eV with an on-site Coulomb interaction of 4 eV for Tb atoms. Transport properties is computed using the BoltzTrap code. The calculated figure of merit (ZT) is 0.97 at 800 K, which indicates the suitability of BaTbO$_3$ as an efficient thermoelectric material.

2:03PM G27.00015: NMR and Mössbauer study of p-type half-Heusler thermoelectrics

YEFAN TIAN, RUI LI (Presenter), FARIT VAGIZOV, NADER GHASSEMI, Department of Physics and Astronomy, Texas A&M University, WUYANG REN, HANGTIAN ZHU, ZHIFENG REN, Department of Physics, University of Houston, JOSEPH HANSBRO ROSS, Department of Physics and Astronomy, Texas A&M University — To investigate the local behavior of defects and mixed compositions in NbFeSb-based semiconductors, for improved thermoelectric efficiency, we have performed $^{93}$Nb and $^{121}$Sb NMR, as well as Mössbauer measurements, on pure NbFeSb and a series of p-type Ti-substituted (Nb,Ti)FeSb samples with different substitution levels. A small but consistently increasing paramagnetic defect density is observed with the increase of Ti substitution level revealing the existence of additional Ti-induced paramagnetic defects. NMR line shapes show a clear difference between effect of intrinsic and extrinsic defects in NbFeSb. The NMR shifts can be well understood by a model combining a Knight shift and composition-dependent chemical shift. The results indicate a nearly rigid-band behavior for the valence band with a small enhancement of effective mass vs substitution. For pure NbFeSb samples, the Mössbauer spectra include an additional T-dependent singlet. The increase of its area can be explained based on carriers activated into a shallow acceptor-like defect level above the valence band, consistent with the defect activation results obtained with NMR. In samples with Ti substitution, the Mössbauer spectra are consistent with a random neighbor distribution, indicating no preferential local ordering.

Session G28 FIAP GIMS: Infrared Sensing and Imaging 405-407 - Carola Emminger, New Mexico State Univ - Tag(s): Industry, Invited
GeSn alloys with dilute Sn concentrations around the near-infrared indirect to direct transition have been thoroughly investigated in recent years. However, the GeSn alloy system, in much the same way as the HgCdTe alloy, is expected to have a continuum of band gaps that reach a value of zero. Covering this IR spectral range requires much higher Sn concentrations, which are not obviously attainable given the thermodynamic metastability of the Ge-Sn system. Sporadic reports of such alloys have appeared in the literature, but in most cases the samples were unsuitable for band gap determinations.

In this presentation we discuss recent work\(^1\) characterizing the band gap and electronic structure of GeSn alloys which Sn concentrations as high as 33\%. These materials have direct band gaps approaching 0.15 eV (~ 8 μm), thus reaching well into the mid-IR spectral range. The high-quality GeSn films required for optical characterization were grown directly on Si substrates by CVD reactions of polygermanes and stannanes at temperatures between 240-290°C. The structural properties of the films are similar to those of their dilute counterparts, in spite of the fact that the fraction of Sn-Sn bonds is expected to be significant. For example, we find that the lattice parameter of the alloys still follows Vegard's law, as reported for lower Sn concentrations.

Ellipsometric measurements of the complex dielectric function make it possible to determine the band gap by modeling the absorption edge. Our model includes excitonic, band filling (Burstein-Moss), and non-parabolicity effects. We find that the compositional dependence of the band gap cannot be described by a simple quadratic polynomial, as is the case in many alloy systems. The implications of this finding for the ability of the GeSn system to cover the 8-12 μm mid-IR window will be discussed in detail.

11:51AM G28.00002: Antimonides T2SLS Infrared Focal Plane Arrays for Space Remote Sensing Applications* [Invited] SARATH GUNAPALA (Presenter), NASA Jet Propulsion Laboratory — Ga-free type-II strained layer superlattice (T2SLS) mid-wave infrared (MWIR) and long-wave infrared (LWIR) barrier infrared detector (BIRD) such as nBn and xBn focal plane arrays (FPAs) could easily operate at higher operating temperature (i.e. compared to InSb and quantum well infrared photodetectors (QWIP) and FPAs) due to the strong suppression of G-R dark current due to SRH processes as explained earlier. We have successfully fabricated MWIR HOT-BIRD FPA and integrated with a dewar cooler assembly for the CubeSat Infrared Atmospheric Sounder (CIRAS) 6U CubeSat. We have also successfully fabricated LWIR BIRD FPA for the Hyperspectral Thermal Imager (HyTI) 6U CubeSat and it will be integrated with a dewar cooler assembly as well. These antimonides based T2SLS BIRDs outperform existing thermal infrared detectors such as QWIPs and InSb. Another 20-30K higher operating temperature advantage can be achieved when we further improve the performance by hybridizing the T2SLS LWIR BIRD detector array to the high-dynamic range in-pixel digital ROICs. Based on III-V compound semiconductors, the T2SL BIRDs offer a breakthrough solution for the realization of low cost (high yield), highperformance FPAs with excellent uniformity and pixel-to-pixel operability. Therefore, T2SLS MWIR and LWIR BIRD FPA technology is very attractive to Earth and planetary remote sensing instruments.

*The research was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under a contract with the National Aeronautics and Space Administration (80NM0018D004).

12:27PM G28.00003: Low-cost infrared imaging technology development at the Air Force Research Laboratory* [Invited] ARNOLD KIEFER (Presenter), CHARLES REYNER, JOSHUA DURAN, BRUCE CLAFLIN, GAMIINI ARIYAWANSA, JARRETT VELLA, Sensors Directorate, Air Force Research Laboratory — Infrared imaging technology has numerous commercial, military, and scientific applications. As performance requirements increase, so do the costs of fabricating and operating infrared imaging systems. While many high-performance applications can be met using the very well-developed mercury cadmium telluride material system, the overall manufacturing and operational costs of the imaging system as a whole can be prohibitively expensive. The Air Force Research Laboratory (AFRL) is actively exploring various technologies using different materials and device physics to achieve adequate performance for the given application at significantly lower costs. A sample of different technologies will be reviewed with an emphasis on fundamental science and basic research needs.

*AFOSR
Photonics for Mobile Handset through Automotive 3D Sensing Consumer Applications [Invited]  BRANDON COLLINGS (Presenter), Lumentum — Machine learning and predictive algorithms are increasingly providing new opportunities for technology to directly participate in our interaction with the physical world around us. A crucial element of this interaction is the detailed digital characterization of that physical environment as an input to these algorithms. While digital visible light cameras have advanced dramatically, optical sensor systems able to add accurate depth measurements to 2D images within practical consumer environments are being developed to enable new consumer applications. Primary examples of these sensor driven applications include biometric authentication on mobile phone handsets and LIDAR scene mapping for autonomous vehicles. This presentation will provide an overview of the architectures of these 3D sensor systems, their underlying enabling photonic technologies, including VCSEL arrays, narrow linewidth semiconductor lasers, MEMS and optomechanical packaging, and how such complex technological solutions are being successfully brought to the consumer market.

Mid-Wave Infrared Resonant Cavity Detectors [Invited]  GARY W WICKS (Presenter), University of Rochester — The dominant issue confronted by designers and users of mid-wave infrared (MWIR) detectors is their large dark current and its noise-producing fluctuations. MWIR dark current is more than a million times that of short-wave (telecom) IR detectors. Several decades of work on dark current reduction via attention to material quality and epitaxial structure are nearing maturity. Significant improvements in dark current require new approaches. Our approach reduces dark current by reducing the volume of the detector’s absorber layer. A thin absorber layer is located inside an optical cavity formed by two mirrors – the so-called Resonant Cavity Detector (RCD). Optical absorption of the thin layer is typically ~1%, which would produce unacceptably small quantum efficiency (QE) in a single-pass detector. In an RCD, the light passes through the thin absorber many times (~50-100) as it re-circulates within the optical cavity, which produces good QE, and also low dark current. RCDs with QE~50% have achieved nearly 10× reduction in dark current and we expect to eventually reduce dark current by 100×. The RCD approach also affects frequency bandwidth (speed) and spectral bandwidth. RCDs absorbers are ~100× thinner than conventional detectors, which reduces minority carrier transit time, thus the frequency bandwidth is expected to increase to > 10 GHz. The spectral bandwidth, Δ, of RCDs is greatly reduced due to interference of the recirculating light with itself. RCDs with Δ ~ 20 nm have been produced, and Δ ~ 3 nm seems feasible. The narrow Δ and low dark current makes RCDs ideal for narrow band applications, such as detection of lasers or sensing spectrally sharp absorption features of gases. The RCD’s spectral response can be tuned 50-100 nm with detector temperature or the light’s angle of incidence. Finally, we discuss the tolerance on the epitaxial growth, which is significantly tighter for RCDs (1% layer thickness control) than for conventional MWIR detectors.

Session G29 DSOFT GSNP: Emergent Mechanics of Active, Robotic, and Living Materials I 501 - Corentin Coulais, Univ of Amsterdam - Tag(s): Focus
11:15AM G29.00001: Transmission hysteresis and edge modes in bounded space-time composites [Invited] HUSSEIN NASSAR (Presenter), Univ of Missouri - Columbia — The vibrational frequency response of bounded composites, e.g., metamaterials and sonic crystals, is often understood thanks to band diagrams established in the absence of boundaries. Introducing a pump wave that modulates in time the properties of the composite challenges the correspondence between the vibrations picture and the waves picture. The talk revisits this correspondence in the context of the nonreciprocal acoustics of space-time composites. Specifically, we establish in the weak coupling regime how the hybridization of total bandgaps into pairs of one-way bandgaps triggers nonreciprocal hysteresis transmission loops in the space-frequency domain and alters, qualitatively and quantitatively, the vibrational frequency response in the presence of reflecting boundaries. The theoretical analysis is assessed numerically and exploited to shed new light on previously obtained experimental data. Last, extrapolating our study to the strong coupling regime, transmission hysteresis is shown to explain the emergence of topological vibrational modes with one-way edge-bulk and bulk-edge transitions.

11:51AM G29.00002: Motion via Bistability in Viscous Fluids* MOHAMED ZANATY (Presenter), Harvard University, WILLIAM ZUNKER, University of Minnesota-Twin Cities, JOCHEN MUELLER, KATIA BERTOLDI, Harvard University — We study the behavior of bistable beams in viscous media and their application to aquatic locomotion. Specifically, we exploit asymmetric actuation of bistable beams, which leads to a nonreciprocal deformation path. As an example, we use double pinned axially compressed bistable beams. We actuate the beam asymmetrically by imposing an angular position on one of the beam extremities.

Using a combination of numerical simulations and experiments, we find that when the beam is surrounded by a viscous fluid, the position of the stable states is not impacted. However, a higher moment is needed to deform the beam compared to air. Importantly, the beam motion non-reciprocity results in thrust in the axial direction, and, therefore, propulsion. The thrust increases with increasing beam compression.

12:03PM G29.00003: Non-reciprocal solitons in robotic materials  MARTIN BRANDENBOURGER (Presenter), HANS DEKKER, CORENTIN COULAIS, Institute of Physics, University of Amsterdam — The recent development of robotic materials, which are assemblies of building blocks integrating sensors and actuators, enables the implementation of non-conservative interactions within mechanical systems. This opens the way to the emergence of unique large scale mechanical properties.

Here, we use this new platform to generate soliton waves that indefinitely propagate in only one direction.

We show that these waves emerge from a smart balance between mechanical non-linearities and linear non-reciprocal interactions, namely, which preferably transmit motion in one direction. Using experiments, theoretical models and simulations, we rationalize the conditions of existence of these solitons and demonstrate that they exist even in the presence of friction. These results establish new ways to reliably transport mechanical energy.

12:15PM G29.00004: Topological locomotion  KATIA BERTOLDI (Presenter), BOLEI DENG, MOHAMED ZANATY, Harvard University — We investigate how the propagation of the topological domain walls through a metamaterial based on the squares rotating mechanism can be harnessed to generate locomotion. First, we add internal elastic constraints to transform the system into a bi-stable system, with the two energy minima being the two symmetry-related rotated phases. Such metamaterial supports topological solitons that take the deformed metamaterial from one static equilibrium position to another one. Remarkably, our results indicate that by combining the propagation of such finite-width topological solitons with angle-dependent friction (that can be easily realized by putting the system on wheels) we can realize a crawler.

12:27PM G29.00005: Topology by activity in non-Hermitian mechanical metamaterials  COLIN SCHEIBNER (Presenter), WILLIAM THOMAS MARK IRVINE, VINCENZO VITELLI, University of Chicago — A simple view of an active solid is a network of masses interacting via non-conservative bonds. We examine 2D topological lattices equipped with non-reciprocal active bonds that inherit two key properties from their passive counterparts: their interactions conserve linear momentum and depend only on the relative positions of the masses. We characterize the flow of Berry curvature and exceptional points in the resulting non-Hermitian band structure as activity is tuned from the passive limit to the brink of instability. Along this flow, we find a discrete onset of topologically charged bands whose activity threshold can be controlled via zero-mode deformations of the underlying lattice. Simulations and analytical calculations reveal the emergence of persistent edge modes influenced by the interplay of a topologically protected penetration depth and an effective quality factor derived from non-Hermitian gain and loss. Our work sheds light on non-Hermitian band theory and the design of active metamaterials that conserve linear momentum.
**12:39PM G29.00006: The topology of nonlinear mechanical systems**  
PO-WEI LO (Presenter), MICHAEL J LAWLER, Cornell University, CHRISTIAN SANTANGELO, University of Massachusetts Amherst, BRYAN G CHEN, Leiden University, KRISHANU ROYCHOWDHURY, Stockholm University, CHAO-MING JIAN, University of California, Santa Barbara — Following the pioneering work of Kane and Lubensky (and others), commendable advancements have been made in the field of topological mechanics. The majority of the work, however, concerns the topology of linear zero modes primarily engaging the framework of linear response theory (often drawing parallels to electronic responses in topological insulators). We, in the present work, attempt an extension to accommodate nonlinear effects that are more natural to occur in realistic mechanical systems and feature topologically protected zero modes. Invoking the tools of differential geometry, we present an exact theory to demonstrate this topology. Our theory (inspired by topological quantum field theory), remarkably, predicts the existence of a $Z$-type topological invariant which arises only from the nonlinearities and does not demand any symmetry imposition (unlike the linear zero modes). We further include example systems to illustrate the physics.

**12:51PM G29.00007: Mechanical metamaterial inspired by biological tissues**  
XINZHI LI (Presenter), DAPENG BI, Northeastern University — We introduce an amorphous mechanical metamaterial inspired by how cells pack in biological tissues. The spatial heterogeneity in the local stiffness of these materials has been recently shown to impact the mechanics of confluent biological tissues and cancer tumors (Li et al Phys. Rev. Lett. 123, 058101 (2019)). Here we use this bio-inspired model as a design template and show that this heterogeneity can give rise to amorphous cellular solids with large, tunable phononic bandgaps. Unlike in phononic crystals, the band gaps here are directionally isotropic due to their complete lack of positional order. The size of the bandgap can be tuned by a combination of local stiffness heterogeneity and the local elasticity modulus. Finally, we also investigated the possibility of introducing a topological nature in the mechanical response using a hexagonal lattice version of the same model. By tuning the local elasticity moduli, we demonstrate the emergence of a pseudo-spin state and as well chiral mechanical response. This constitutes a mechanical analogue of the quantum spin Hall effect.
1:03PM G29.00008: Modeling tunable acoustic transport in driven graphene nanoresonator arrays

PRAGALV KARKI (Presenter), DAVID MILLER, ANDREW D BLAIKIE, BRITTANY CARTER, BENJAMIN J ALEMAN, JAYSON PAULOSE, Univ of Oregon — Arrays of graphene nanoelectromechanical resonators show promise as a platform for precise, programmable manipulation of acoustic waves at the nanoscale. Besides harboring technologically relevant resonant frequencies and high quality factor, graphene resonators display a remarkable tunability of the local membrane tension through electrostatic back-gating or laser heating, which can be used to modulate vibrational properties. Motivated by experiments, we present a theoretical and computational study of the acoustic properties of coupled graphene resonators with dynamical spatiotemporal modulation of the tension. Starting from the theory of thin elastic plates, we develop a reduced description of the collective modes arising from the coupling of the fundamental modes on individual resonators and evaluate the effects of externally driven changes in tension on wave propagation. We will also describe early efforts at calibrating and testing the model against experimental measurements of coupled resonator acoustic modes. Our results pave the way towards designing driven graphene nanoelectromechanical resonator arrays with a manifestly out-of-equilibrium acoustic response.

1:15PM G29.00009: Transitions from conservative to non-conservative regimes in optical binding of colloidal matter.*

DOMINIQUE DAVENPORT (Presenter), DUSTIN KLECKNER, University of California, Merced — We study light generated inter-particle interactions known as optical binding. These forces are mediated by the particle light scattering making it uniquely responsive to simple changes in the parameter space. For instance, we find that many colloidal particles placed in a weakly focused laser beam can self-assemble into higher-order and multi-leveled structures which can be tuned with simple alterations. We share experimental results which conclude a dramatic change in assembly patterns by changing particle index of refraction; namely, a switch between a conservative pair-wise regime to highly non-conservative many-body regime.

*Hellman Fellows Fund

1:27PM G29.00010: What kinds of forces does optical binding produce?*

DUSTIN KLECKNER (Presenter), DOMINIQUE DAVENPORT, University of California, Merced — Optical binding is an attractive tool for controlling colloidal forces because it offers a highly tunable method of producing inter-particle forces without chemical modifications. Previous studies of optically bound particles have tended to focus on small numbers of particles in relatively static configurations. By contrast, our experimental studies of many wavelength sized particles exhibit novel dynamics which are indicative of driven, non-conservative forces. I will discuss how these forces arise, and how they might be controlled to study colloidal dynamics in novel regimes.

*This work was supported by a grant from the Hellman Fellows Fund.
1:39PM G29.00011: The odd flows of a colloidal chiral fluid* EPHRAIM BILILIGN (Presenter), VISHAL H SONI, University of Chicago, SOFIA MAGKIRIADOU, École Polytechnique Fédérale de Lausanne (EPFL), STEFANO SACANNA, New York University, DENIS BARTOLO, École Normale Supérieure de Lyon, MICHAEL JOHN SHELLEY, New York University, WILLIAM THOMAS MARK IRVINE, University of Chicago — We report the assembly of a chiral fluid composed of millions of spinning colloidal magnets. By activating the fluid at the single unit level, we observe macroscopic flows with no counterpart in conventional fluids. Odd viscous stresses drive the propagation of unidirectional free-surface waves damped by odd (or Hall) viscosity. Further, the competition between odd stress and cohesive forces results in intermittent bulk flows, blurring the distinction between solid and liquid.

Session G30 DSOFT DPOLY DBIO: Self-Limiting Assemblies III: Soft Assemblies and In and Out of Equilibrium 502 - Gregory Grason, Univ of Mass - Amherst

11:15AM G30.00001: Pitch-balanced helical motifs in tightly packed lamellar structures EFI EFRATI (Presenter), Weizmann Institute of Science — Many biological and manmade lamellar structures form minimal surfaces due to surface area or bending energy minimization (or both). Recently, the endoplasmic reticulum sheets were shown to contain both right and left-handed helical motifs at equal amounts. In this talk, I will show that the lamellar structures that house photosynthesis in some plants, the thylakoid, also display right and left-handed motifs. The oppositely handed motifs, unlike those of the endoplasmic reticulum, differ in pitch and diameter, yet the stoichiometry is such that pitch is balanced between the differently handed motifs. We argue that the optimal packing of helical motifs in lamellar structures requires global pitch balance. We support this by a new constructive recipe that allows us to generate exact minimal surfaces with any arrangement of helical motifs.
11:27AM G30.00002: Colloidal membrane thickness sets critical surface area for vesicle formation*  JOANNA ROBASZEWSKI (Presenter), Brandeis University, LEROY JIA, THOMAS R POWERS, ROBERT ALAN PELCOVITS, Brown University, ZVONIMIR DOGIC, University of California, Santa Barbara — The malleable size and shape of biological membranes allow them to act in a wide range of cellular functions. Vesicles in particular have different uses, from transport to compartmentalization, depending on their size and shape. However, the rapidity with which bio-membranes bend and change structure on the nanoscale makes studying the physics that drive these changes difficult. We use colloidal membranes as experimental models to study the forces governing vesicle formation. Due to the larger length and time scales present in our colloidal system, we directly observe membranes undergoing lateral growth and then bending into vesicles. Both theory and experiment indicate that the size of the final vesicle structure depends on the thickness of the membrane. By tuning the thickness of our colloidal membranes, we can set the critical surface area at which a flat sheet will transition into a vesicle. Our system therefore allows for direct probing of vesicle formation physics, measurement of physical properties, and control over membrane curvature and structure size.

11:39AM G30.00003: How Curvature and Tension Direct Morphology and Interactions of Solid Membrane Domains in Fluid Vesicles*  MARIA SANTORE (Presenter), WEIYUE XIN, HAO WAN, Univ of Mass - Amherst — Multi-phospholipid giant unilamellar vesicles containing at least one high melting lipid (such as DPPC) exhibit the coexistence of fluid and solid membrane domains. To the extent that the inner and outer leaflets of the membrane are matched in composition and molecular number, symmetry dictates flat solid domains. The curvature imposed we show that at sufficiently high tensions, the curvature imposed by global vesicle shape influences the growth of solid domains, producing deviations from hexagon domain shape to include edge instabilities that appear as flowers. At high tensions domains appear to fracture. At lower tensions, exclusion of curvature into the fluid membrane region produces reversible interactions between solid domains that give rise to aggregation or long range order, depending on the relative sizes of vesicle domains, curvature, and excess membrane area. These behaviors are demonstrated in a model experimental vesicle system.

**11:51AM G30.00004: Collapse and folding of flexible colloidal polymers**  
ANGUS MCMULLEN, JASNA BRUJIC (Presenter), Physics, New York University — The self-assembly of colloids can yield novel materials with unusual optical or mechanical properties. Unlike periodically repeating structures, here we introduce a new paradigm of self-assembly in which flexible colloidal polymers find a ‘fold’, similar to the way polypeptides fold into proteins. We have previously shown how emulsion droplets decorated with DNA sticky ends self-assemble into freely-jointed polymers. Here, we demonstrate the addition of secondary, switchable interactions along the length of a self-assembled polymer. These interactions are triggered by a temperature quench, whose rate governs the folding pathways from the extended to the collapsed states. The folding time scales with the length of the chain, in agreement with the increase in entropy. Using the simplest form of sequence control, we show that labeling alternating particles with secondary interactions eliminates some folding pathways visited when all droplets along the chain interact, narrowing the ensemble of folded configurations. This result opens up the prospect of programmable sequence design to achieve a unique stable structure, as the Anfinsen’s dogma for protein folding proposes. This work was supported by the NSF MRSEC Program (DMR-0820341).

**12:03PM G30.00005: Dissolving a DNA liquid through competition**  
GABRIELLE ABRAHAM (Presenter), OMAR SALEH, University of California, Santa Barbara — Coacervation plays a key role in spatial and temporal organization within the cell. Short nucleic acids are one mechanism that has been shown to control the intracellular dense liquids (e.g., introducing or removing short nucleic acids causes changes in the properties and appearance of droplets.) Here, we employ a model DNA liquid system and quantify the dissolution by short nucleic acids. Previous work has confirmed that this system is similar to intracellular droplets in terms of physical properties and spatial control (i.e., specific molecules are enriched or depleted in the droplet phase). The liquid is comprised of DNA in the shape of a 4-armed nanostar with each arm ending in a palindromic sequence that allows nanostars to interact and condense into droplets. By incorporating a toe-hold sequence on the nanostar, short hairpins are able to outcompete the nanostars for interaction sites causing the droplets to dissolve. Using confocal microscopy, we track DNA liquid break-up and compare the rate of decay to hairpin-nanostar interaction strength, concentration of the hairpin, and toe-hold location. This work will give insight into the different mechanisms that drive coacervate dissolution.
12:15PM G30.00006: Theory and simulation of reaction diffusion models of self-limiting droplet formation*  TREVOR GRANDPRE (Presenter), Physics, University of California, Berkeley, DAVID T. LIMMER, Chemistry, University of California, Berkeley — Liquid droplets are a generic feature of biological systems. Within the cell, liquidlike substructures form that contain Cajal bodies, germ granules, and centrosomes. In the absence of surfactants or long ranged interactions, the thermodynamically stable phase separated state of a liquid will always be that which minimizes the surface area of the droplet resulting in macroscopic domains. For this reason, it remains unclear how cells mitigate the formation of such large scale structure. We discuss ways in which macroscopic domains can be avoided by slow coarsening dynamics accompanying gelation or active processes that modulate Ostwald ripening. Theory and computer simulations are used to understand the mechanisms of droplet formation and dynamics. Implications for T-cell signaling pathways are also discussed.

12:27PM G30.00007: Nonequilibrium Variational Control Forces for Self-Limited Colloidal Assembly*  AVISHEK DAS (Presenter), DAVID T. LIMMER, University of California, Berkeley — Materials with tunable functionalities can be synthesized bottom-up by controlled self-assembly of colloidal particles. Design principles that are rooted in thermodynamic principles and optimize specific interactions are often thwarted by kinetic limitations and confined to compact surface energy minimizing structures. We discuss a variational principle for the optimization of interparticle and nonequilibrium driving forces, which lead to robust assembly of self-limited clusters. Molecular dynamics simulations and a novel optimization strategy are used to solve for these optimal control forces. Our results expand the design space outside thermal equilibrium and provide new principles for tuning the dynamics of self-limited assembly in colloidal systems.

*This work was supported by the UC Berkeley College of Chemistry and the U.S. Department of Energy, Office of Basic Energy Sciences through Award Number DE-SC0019375.
12:39PM G30.00008: Kinetic entrapment: a mechanism for periodic one-dimensional growth  THOMAS WITTEN (Presenter), James Franck Institute, University of Chicago, MARTIN Lenz, LPTMS, CNRS, Université de Paris Sud — Globular proteins and other irregularly-shaped but identical molecular objects often self-assemble into fibers such as sickle-cell hemoglobin fibers. Such fibers are typically one-dimensional aggregates of fixed width, indefinitely long length and strong periodic order. A recent numerical study [Lenz, Witten 2017] gave strong evidence that such one dimensional fibers arise generically when a) the constituents are identical, b) their shape is asymmetric, so that they do not tile space, c) they aggregate irreversibly under the influence of a short-range attraction, and d) the energetic cost of distorting the constituents into bonding configurations is comparable to the attachment energy gained by this bonding. Here we propose a common kinetic mechanism in which the next growth site is a generic, deterministic function of the current aggregate configuration. We take the growth function to depend only on a local neighborhood of the previous growth site. A small bias favoring convex regions causes the growth site to revisit a given neighborhood of the deposit sufficiently often that the sequence of neighborhoods and growth sites reliably falls into a fixed, repeating cycle. This self entrapment does not occur when the bias parameter is halved.

12:51PM G30.00009: Pattern recognition through molecular self-assembly*  CONSTANTINE G EVANS, Maynooth University, JACKSON O'BRIEN (Presenter), University of Chicago, ERIK WINFREE, California Institute of Technology, ARVIND MURUGAN, University of Chicago — The functional role of many weak promiscuous interactions among molecules in biology is not clear and is often assumed to be deleterious. Here, we exploit promiscuous interactions to engineer an experimental system of 917 single-stranded DNA molecules capable of associative pattern recognition on the high dimensional concentration patterns of these molecular assembly components. Such pattern recognition is achieved by exploiting a process of competitive nucleation between different polymorphic DNA structures that are predominantly made of the same molecules but co-localized in different combinations. We test the system with numerous concentration patterns and confirmed nucleation-based pattern recognition through Atomic Force Microscopy (AFM) and fluorescence measurements. We discuss how this system, in conjunction with additional enzymatic components (e.g. DNA ligase), can potentially learn the promiscuous interactions needed to perform unsupervised clustering of concentration patterns.

*NSF-MRSEC 1420709
1:03PM G30.00010: Strain-Adaptive Self-Assembled Networks of Linear-Bottlebrush-Linear Copolymers* HEI LIANG (Presenter), ZILU WANG, ANDREY DOBRYNIN, Univ of Akron — We study the strain-adaptive behavior of the self-assembled networks of linear-bottlebrush-linear (LBL) triblock copolymers using a combination of analytical calculations and molecular dynamics simulations. Interactions between immiscible blocks result in microphase separation and formation of soft and strain-adaptive composite networks. Such unique network properties are manifestations of the architectural asymmetry of two blocks: (i) flexible linear chains that aggregate into domains and (ii) bottlebrush strands that form a soft matrix. The mechanical response of the networks is a two-stage process, which starts with the extension of the bottlebrush network strands (elastic regime) followed by the pulling out of the linear chains from L-domains (yielding regime). The two-stage network deformation process is incorporated into a unifying model of strain-adaptive network deformation. The model predictions are confirmed by molecular dynamics simulations of uniaxial deformation of self-assembled LBL copolymer networks and by experimental results for copolymers consisting of poly(dimethyl siloxane) bottlebrush block and two poly(methyl methacrylate) linear chain blocks with different compositions and block lengths.

*NSF DMR-1535412, DMR-1921923

1:15PM G30.00011: Self-directed Self-assembly of Block Copolymers HEJIN HUANG (Presenter), ALFREDO ALEXANDER-KATZ, Materials Science and Engineering, Massachusetts Institute of Technology MIT — Directed self-assembly (DSA) of block copolymers (BCP) provides a powerful tool to fabricate complex thin film structures at small length scale. Despite its success in fabricating various 2D patterns, fabrication of complex 3D nanostructures remains a challenge. Here, we introduce a novel method, which enables self-directed self-assembly of 3D tailored nanostructures. Dissipative particle dynamics (DPD) is employed, which demonstrates that uniform multilayer nanostructures could be obtained through stacking two different block copolymers alternatively. By introducing graphoepitaxy or chemoepitaxy to the first layer and performing multilayer stacking, information propagates upwards. Different complex bilayer and trilayer structures have been achieved through carefully choosing the BCP used in each stacking layer. We will show several examples of the complex uniform multilayer structures.
Identification of a Frank–Kasper Z phase from shape amphiphile self-assembly

STEPHEN CHENG (Presenter), MINGJUN HUANG, South China University of Technology, South China Advanced Institute for Soft Matter Science and Technology, ZEBIN SU, Univ of Akron —

Frank–Kasper phases, a family of ordered structures formed from particles with spherical motifs, are found in a host of materials, such as metal alloys, inorganic colloids and various types of soft matter. All the experimentally observed Frank–Kasper phases can be constructed from the basic units of three fundamental structures called the A15, C15 and Z phases. The Z phase, typically observed in metal alloys, is associated with a relatively large volume ratio between its constituents, and this constraint inhibits its formation in most self-assembled single-component soft-matter systems. We have assembled a series of nano-sized shape amphiphiles that comprise a triphenylene core and six polyhedral oligomeric silsesquioxane cages grafted onto it through linkers to give a variety of unconventional structures, which include the Z phase.

Theory of Complex Spherical Packing Phases in Surfactant Systems

JIAYU XIE (Presenter), CHI TO LAI, ANCHANG SHI, McMaster Univ — The emergence and stability of complex spherical phases from a vast number of soft matter systems have been attracting tremendous attention recently. In particular, recent experiments have demonstrated the formation of Frank-Kasper and Laves phases (A15, σ, C14 and C15) in surfactant systems. Specifically, it has been shown that micelles self-assembled from amphiphilic molecules in water could pack and form these complex spherical packing phases in the presence of hydrocarbon molecules. Theoretically, we model the surfactant molecules by short diblock copolymers composed of a hydrophilic head and a hydrophobic tail. The phase behaviour of the model system is examined by using self-consistent field theory applied to a model system of short diblock copolymers and homopolymers. Our results indicate that the complex spherical packing phases could become stable for a set of model parameters corresponding to surfactant systems. Phase diagrams containing a large number of complex phases are constructed. The theoretical results demonstrate that the emergence and stability of complex spherical packing phases could be regulated by surfactant composition and concentration, thus shedding light to the understanding of the formation mechanisms of complex phases in soft matter systems.

1:51PM G30.00014: Predictive Modeling of Dendrimer Directed Nanoparticle Self-Assembly*

THI VO (Presenter), Chemical Engineering, University of Michigan - Ann Arbor, KATHERINE ELBERT, Chemistry, University of Pennsylvania, NADIA KROOK, Materials Science and Engineering, University of Pennsylvania, WILLIAM E ZYGMUNT, Chemical Engineering, University of Michigan - Ann Arbor, JUNGMI PARK, Chemistry, University of Pennsylvania, KEVIN YAGER, Center for Functional Nanomaterials, Brookhaven National Laboratory, RUSSELL COMPOSTO, Materials Science and Engineering, University of Pennsylvania, SHARON C GLOTZER, Chemical Engineering, University of Michigan - Ann Arbor, CHRISTOPHER B MURRAY, Chemistry, University of Pennsylvania — Traditional methods in nanocrystal self-assembly often rely on linear ligands isotropically grafted onto spherical cores. More recently, there has been a shift towards utilizing cores of varying shapes to expand on the current library of accessible morphologies. However, predictive simulations and designed experiments combining both the effect of ligand architecture as well as their anisotropic grafting onto nonspherical cores for self-assembly are still in their infancy. Here, we present a combined experimental and theoretical study in which a series of dendrimer ligands are used to direct the assembly of nanoplates into 2D and 3D geometries. We show that dendrimer ligands can be used to tune the degree of corona anisotropy about the nanoplates that then drives the formation of an off-set, layer-by-layer nanoplate architecture observed experimentally in 3D films. Our findings show that ligand architecture serves as a handle for layer specific, fine-tuning of self-assembly and provide a systematic approach to theoretically predict morphology purely from experimental design parameters.

Shape and Interaction Decoupling for Colloidal Pre-Assembly

Lucia Baldauf, University of Amsterdam, Erin Teich, University of Michigan, Greg Van Anders (Presenter), Queen's University, Peter Schall, University of Amsterdam, Laura Rossi, Delft University of Technology — Creating materials with a structural hierarchy that is independently controllable at a range of scales requires breaking naturally occurring hierarchies. Breaking natural hierarchies is possible if building block attributes can be decoupled from the structure of pre-assembled, mesoscale building blocks that form the next level in the structural hierarchy. Here, we show that pre-assembled colloidal structures achieving geometric and interaction decoupling can be prepared in emulsions of silica superballs, which are cubic-like particles with rounded edges. We show that, for clusters of up to nine particles, colloidal superballs pack consistently like spheres, despite the presence of shape anisotropy and facets in the cubic-like particles. We compare our results with clusters prepared with magnetic superballs and find good qualitative agreement, suggesting that the cluster geometries are solely determined by the shape of the constituent particles. Our findings demonstrate that highly shape-anisotropic building blocks, under suitable conditions, can be pre-assembled into structures that are not found in bulk, thereby achieving a decoupling that can be further exploited for hierarchical materials development.

Topological states of hard rods in extreme annular confinement*

René Wittmann (Presenter), HHU Düsseldorf, Louis Brian Georges Cortes, Dirk Aarts, University of Oxford, Hartmut Löwen, HHU Düsseldorf — Hard particles are a standard model for colloidal systems and can be effectively studied within classical density functional theory (DFT). Fundamental mixed measure theory (FMMT) allows to predict the phase behavior of a hard-body fluid solely from the shape of individual particles.

Recent experimental advances allow for the synthesis of colloids with a nearly hard interaction that can be analyzed on the single-particle level. Slices of a system of such silica rods confined in a three-dimensional chamber under gravity can be considered a quasi-two-dimensional fluid that exhibits typical liquid-crystal behavior in confinement.

Applying FMMT to hard discorectangles in two dimensions, we map out a full phase diagram. Then we focus on a smectic fluid in extreme complex confinement, where the optimal bulk layer spacing competes with the extrinsic geometric and topological constraints. As a result, we characterize a variety of topologically different states in an annular geometry, also observed in particle-resolved experiments with silica rods. By further comparing the free energy of the different states, naturally provided by our DFT, we map out a topological phase diagram, indicating the stable topology depending on the details of the annular confinement.

11:39AM G31.00003: Do cavities matter? Suppression of crystallization in hollow microgel solutions  ANDREA SCOTTI (Presenter), RWTH - Aachen University, ALAN DENTON, North Dakota State University, MONIA BRUGNONI, RWTH - Aachen University, RALF SCHWEINS, ILL Institut Laue-Langevin, WALTER RICHTERING, RWTH - Aachen University — Microgels are crosslinked polymeric networks in the colloidal domain that exhibit phase behavior comparable to soft spheres. Solutions of microgels have been widely used as model systems to study self-assembly of condensed matter and complex fluids. Here we study the phase behavior of hollow microgels, characterized by a solvent-filled cavity in their center. Surprisingly, the phase behavior of these microgels, which lack a dense polymeric core, does not show crystal formation. The absence of crystals is independent of both the softness of the network and the size of the cavity. By means of small-angle neutron and X-ray scattering, both the form factors and the interparticle separations of hollow microgels are measured in overcrowded environments, revealing a complex interplay between interpenetration and deswelling. We confirm these findings by Monte Carlo simulations of microgel solutions modeled by the Flory-Rehner single-particle free energy and the Hertz pair potential.

11:51AM G31.00004: Buckling of 2D complex plasma crystals  ALEXANDRA ZAMPETAKI (Presenter), ALEXEI IVLEV, Max-Planck Institute for Extraterrestrial Physics, HARTMUT LOEWEN, University of Dusseldorf — Complex plasmas (or dusty plasmas) consist of microsized dust particles and a weakly ionized gas and as such they are often regarded as the "plasma state of soft matter". Apart from their particularly strong coupling, such systems exhibit also other surprising properties, such as a non-Hamiltonian behavior, due to the emergent plasma wakes. In this talk I will present some very recent theoretical results about the ways in which the existence of plasma wakes affects the structure of complex plasma crystals under a harmonic confinement. The main focus thereof will be on the buckling transition from a 2D monolayer to bilayer or triple-layer complex plasma crystals, taking place as the confinement frequency is decreased. Such structural transitions provide further insight to the underexplored properties of systems with effective non-reciprocal interactions occurring often in non-equilibrium soft matter.

12:03PM G31.00005: Tuning Interactions between Charged Structured Colloids and Hydrophobic Salts for the Production of Pickering Emulsifiers  DOUGLAS SCOTT (Presenter), ROBERT K PRUD'HOMME, RODNEY PRIESTLEY, Chemical & Biological Engineering, Princeton University — Pickering emulsifiers have been demonstrated as advantageous alternatives to traditional small molecule surfactants, owing to their high interfacial adsorption energy and mechanical functionality. However, translating these advantages on an industrial scale requires continuous fabrication processes. Flash nanoprecipitation (FNP) has been demonstrated as a scalable process for the production of nanocolloids with a rich library of morphologies including homogeneous, core-shell, and Janus structures, the last of which presents an opportunity for generating amphiphilic Pickering emulsifiers. In this work, the FNP of homopolymers with ionomer analogs is presented as a route for the tunable expression of charge groups on distinct hemispheres of Janus particles. Utilizing this enhanced surface charge, the interaction between colloids and hydrophobic salts is studied, showing non-monotonic trends in size stability. Lastly, the surface activity of various colloid-salt combinations is demonstrated via the formation of highly stable Pickering emulsions.
12:15PM G31.00006: Bayesian inference of particle size distributions from dynamic light scattering* THY DOAN MAI LE (Presenter), JEROME FUNG, Ithaca College — Autocorrelation functions from dynamic light scattering experiments have previously been analyzed either by performing least-squares fits to determine the mean and variance of the particle size distribution, or by using constrained regularization techniques to infer the size distribution. We present open-source tools for performing Bayesian inference of particle size distributions while rigorously incorporating smoothness and non-negativity constraints on the inferred distributions. We successfully apply these tools to simulated autocorrelation functions at multiple scattering angles. We intend to release these tools for use by the soft condensed matter and biophysics communities in the near future.

*This project was funded by the Charles A. Dana Internship fund and the School of Humanities & Sciences' Summer Scholars program at Ithaca College.

12:27PM G31.00007: Confinement of colloidal smectic phases* LOUIS BRIAN GEORGES CORTES (Presenter), Cornell University, RENÉ WITTMANN, Heinrich Heine University Düsseldorf, ROEL P. A. DULLENS, University of Oxford, HARTMUT LÖWEN, Heinrich Heine University Düsseldorf, DIRK AARTS, University of Oxford — We report on the confinement of colloidal liquid crystals in three dimensional chambers. We exploit silica rods’ relatively large density difference with respect to the dispersing solvent to study isotropic, nematic and smectic phases confined into a single chamber. Combining laser scanning confocal microscopy and soft-lithography techniques enables us to characterize the configurations down to the single particle level. We focus on the smectic phase observed in direct vicinity of the bottom wall. We first consider chambers with square footprint finding occurrences of the smectic bridge state, characterized by two parallel disclination lines, in good agreement with simulation of 2-dimensional hard rods. We then examine the case of topologically different annular chambers. By progressively varying the confinement from a disk to a thin annulus we induce a transition from the smectic bridge state, formerly found in square, to the smectic ring state with distinctive edge dislocations. The results are compared to very recent density functional theory calculations.

*This project has received funding from the European Union’s Horizon 2020 research and innovation programme under the Marie Sklodowska-Curie Grant Agreement No 641839.
12:39PM G31.00008: Molecular dynamics simulations resolve the encapsulation of testosterone propionate by both solid and liquid lipid nanoparticles  DEMI PINK (Presenter), Physics, Kings College London, JAYNE LAWRENCE, Division of Pharmacy & Optometry, University of Manchester, CHRISTIAN D. LORENZ, Physics, Kings College London — Solid lipid nanoparticles (SLNs) have a crystalline lipid core which is stabilised in solution by interfacial surfactants. They are considered favourable candidates for future drug delivery vehicles as they are capable of storing and release bioactive molecules. Following our successful study on the self-assembly of the SLN and our characterisation of the resulting structure, we have expanded our work to investigate the formation of triolein-based liquid lipid nanoparticles (LLNs) stabilised by the Brij O10 surfactant. LLNs are, like SLNs, of interest for their potential applications in drug delivery and so a thorough understanding of their structure is vital in the development and optimisation of drug delivery formulations. In this work we have characterised the structure and formation of LLNs by means of small angle neutron scattering and atomistic molecular dynamics simulations. We have also characterised and compared the processes involved in the encapsulation and localisation of a steroidal drug, testosterone propionate, for both the SLN and the LLN. By comparing the two nanostructures and the localisation of the drug within them we have shed light on the relationship between a nanoparticle’s internal structure and its role in drug delivery.

12:51PM G31.00009: Dynamics and contact microstructure of rough colloids*  SHRAVAN PRADEEP (Presenter), LILIAN C HSIAO, North Carolina State University — Colloidal particles with hard-sphere interactions have been used to study crystallization and glassy dynamics. Here we synthesize smooth and rough poly(methyl methacrylate) colloids and disperse them in an index-matched solvent, squalene, at volume fractions (Φ) ranging from dilute (Φ=0.1) to random close packing (RCP). We use confocal microscopy to obtain 3D image-stacks of the colloidal suspensions and process them to obtain particle centroids with subpixel precision. We estimate the contact numbers for smooth and rough colloids at RCP to be 6 and 4 respectively, as predicted by simulations of frictional granules. In both the systems, scaling of the form <z>~Φ^a was observed, where parameter 'a' varies with surface roughness. We hypothesize that the power law variations are related to the phase behaviors and associated dynamics (mean-squared displacement) of these particles at various Φ. We believe our approach to connect the contact microstructure to dynamics in suspensions will enable better understanding of the effect of surface anisotropy on colloidal crystallization, rheological phenomena, and osmotic pressure of suspensions.

1:03PM G31.00010: Liquid crystal-mediated growth and assembly of polymer colloids*
XIAOSHUANG WEI (Presenter), LAURA BRADLEY, Univ of Mass - Amherst — Templating the director field of liquid crystals (LCs) has been shown to organize colloids into a variety of ordered assemblies, including chain-like structures and hexagonal lattices. Most systems produce LC-mediated assemblies by pre-mixing colloids in host mesogens or by depositing colloids at LC interfaces. In our work, we demonstrate simultaneous growth and assembly of polymer colloids at LC-air interfaces. The polymer colloids are produced by polymerization of acrylate monomer mixed in non-reactive liquid crystal mesogens. Colloids spontaneously form ordered assemblies at the LC-air interface. Systematic experiments varying the reaction time were conducted to monitor the nucleation, growth, and assembly. Simultaneous colloid growth and assembly in LCs can open new opportunities to utilize LC-templated polymerization for the preparation of large-scale assemblies or continuous network structures.

*This work is supported by an NSF CAREER Award (#1845631).

1:15PM G31.00011: Holographic Perfusion Porosimetry of Individual Colloidal Particles*
DAVID G GRIER (Presenter), Department of Physics, New York University, MARY ANN ODETE, FOOK C CHEONG, ANNEMARIE WINTERS, Spheryx, Inc., JESSE J ELLIOTT, Department of Physics, University of Chicago, LAURA A PHILIPS, Spheryx, Inc. — The in-line hologram of a micrometer-scale colloidal sphere can be analyzed with the Lorenz-Mie theory of light scattering to obtain precise measurements of the sphere's diameter and refractive index. The same technique also can be used to characterize porous and irregularly shaped colloidal particles provided that the extracted parameters are interpreted with effective-medium theory to represent the properties of an equivalent effective sphere. We demonstrate through experiments on mesoporous silica spheres, protein aggregates and nanoparticle agglomerates that the effective-sphere model consistently accounts for the influence of the medium on the particle's measured effective refractive index. This dependence yields information on the particles' structure and composition that cannot be obtained in other ways, including their porosity, the polydispersity of their porosity, and the size distribution and connectivity of their pores.

Additional support was provided by the MRSEC program of the National Science Foundation under award number DMR-1420073.
1:27PM G31.00012: Controlling the flexible polymer - hard colloid duality of temperature-responsive microgels at interfaces by the adsorption pathway*  MARIE FRIEDERIKE SCHULTE (Presenter), ANDREA SCOTTI, STEFFEN BOCHENEK, MONIA BRUGNONI, WALTER RICHTERING, RWTH - Aachen — We study the effect of the adsorption pathway on the morphology and temperature-induced collapse of PNIPAM microgels at the solid/liquid interface by means of atomic force microscopy (AFM). Two samples with extreme differences in softness are probed: i) regularly 5 mol% BIS, and ii) ultra-low cross-linked microgels (ULC). ULC microgels are strongly deformed when being deposited either by spin-coating or by Langmuir-Blodgett technique from an oil-water interface. After rehydration, the ULC microgels cannot collapse as entire objects instead small globules are formed. Such a strong deformation can be avoided by in-situ adsorption to the substrate. Then, the ULC microgels exhibit half-ellipsoidal shapes with a smooth surface similar to more cross-linked microgels. Due to the extreme softness of ULC microgels, they can be selectively trapped either in a more particle-like or in a more polymer-like behavior. Coatings with strongly different topographies and properties can be prepared by one and the same ultra-low cross-linked microgel.

1:39PM G31.00013: Localization to delocalization transitions in size asymmetric mixtures of colloidal particles with grafted chains*  HECTOR MANUEL LOPEZ RIOS (Presenter), ALI EHLEN, MONICA OLVERA DE LA CRUZ, Northwestern University — We study binary systems of polymer-grafted colloidal particles, in which the diameter of one species is substantially larger than the other. It has recently been shown [1] that, in these systems, the larger colloids order to form a lattice while the smaller ones may form a sublattice or delocalize within the interstitial space, depending on system parameters. We develop a simplified molecular dynamics model to study these colloidal systems and the nature of the delocalization of the smaller species under varied conditions. Using this model, we explore phase transitions between different lattice and sublattice types as a function of temperature.

*We acknowledge and thank the computational support of the Sherman Fairchild Foundation.
Two Coupled Mechanisms Produce Fickian, yet non-Gaussian Diffusion in Heterogeneous Media

INDRANI CHAKRABORTY (Presenter), YAEL ROICHMAN, School of Chemistry, School of Physics & Astronomy, Tel Aviv University — In several biological and soft matter systems, Fickian yet non-Gaussian diffusion has been observed, where the mean square displacement remains linear in nature, but the displacement distribution is non-Gaussian. The underlying reasons behind this strange behavior still remain speculative. Here, we perform a set of controlled experiments that quantitatively explore the effect of spatial heterogeneities on the appearance of non-Gaussianity in Fickian diffusion. Specifically, we study the diffusion of fluorescent colloidal particles in a matrix of lithographically fabricated micropillar arrays having a range of structural configurations: from completely ordered to completely random. Structural randomness and density are found to be the two most decisive factors in making diffusion non-Gaussian. We show that non-Gaussianity emerges as a direct consequence of two coupled physical mechanisms that produce a superstatistical behavior of the ensemble in a structurally heterogeneous environment. The two mechanisms identified here are relevant for many systems of crowded heterogeneous environments where non-Gaussian diffusion is frequently observed, for example in biological systems, polymers, gels and porous materials.

Session G32 DPOLY DSOFT DBIO: Responsive Polymers, Soft Materials, and Hybrids III

Ordering hard-sphere particle suspensions by medium crystallization: Effect of size and interaction strength* VIANNEY GIMENEZ-PINTO (Presenter), Department of Science, Technology and Mathematics, Lincoln University, Missouri — While microstructure in soft materials is usually given by the self-assembly of their constituting building blocks, colloidal assembly can also be obtained via templating a morphology in a disordered suspension of particles by solidification of the melt. This sweep-templating process is applicable in different soft matter systems with a variety of characteristic length scales, including particle suspensions in water, liquid crystal materials, and polymer melts. Here, I numerically investigate the effect of particle-size and solvent-size in the process of solidification templating by implementing a simple coarse-grain model for the kinetics of hard-sphere particles at the melt/crystal interface. Results show that the threshold speed for solidification templating trails a power-form as size changes. Furthermore, this work analyzes and reports the effect of particle-crystal interaction strength in combination with size effects. This scaling study from a numerical perspective sets a starting point for the development of hybrid soft materials via structural templating, allowing solidification-driven particle ordering in different systems with length-scales that range from a few tens of nanometers to microns and centimeters.

*Work funded by NSF DMR-1408323
11:27AM G32.00002: Exploring Solution Behavior of Fully Rigid “Block Copolymers” with Sphere-Rod Molecular Architecture* JIANCHENG LUO (Presenter), TONG LIU, STEPHEN CHENG, TIANBO LIU, Univ of Akron — The rich solution behavior of block copolymers, especially self-assembly of amphiphilic block copolymers in solution, have been extensively explored in past decades. While the traditional block copolymers often involve flexible chains, some novel “copolymers” containing rigid components might also demonstrate interesting self-assembly behavior. Here, we explore solution behavior of fully rigid “block copolymers” hybrid macromolecules based on spherical polyoxometalates and rod-like oligofluorenes. We report here that rigid macromolecules can achieve continuous curvature change and consequently form unexcepted multilayer vesicular structures. The highly uniform, multilayered vesicles have complete onion-like structure from most inner to outer layers with fixed interlayer distance, and the vesicle size/layer number can be accurately controlled by solution conditions including temperature, solvent composition, and salt concentration. Additionally, reversible response of vesicle size/layer number is observed by simplify changing the solution temperature. The effects of rod length and molecular architecture will also be discussed.

11:39AM G32.00003: Stimuli-responsive phase behavior of block copolymers in ionic liquids CLAIRE SEITZINGER (Presenter), CECILIA C HALL, TIMOTHY LODGE, University of Minnesota — Block copolymers microphase separate into well-defined ordered morphologies as a function of temperature and composition. However, not all applications are amenable to changes in temperature or composition, but still require transitions between disorder and order, or between different ordered symmetries. We explore the light-mediated phase behavior of a diblock copolymer, poly(methyl methacrylate)-b-poly(benzyl methacrylate-s-4-phenylazophenyl methacrylate), in a selective ionic liquid solvent, 1-alkyl-3-methyl imidazolium bis(trifluoromethylsulfonyl)imide. By adjusting the length of the alkyl chain on the imidazolium group, we can control the phase transition temperatures (order-disorder and order-order transitions). In this system, the solubility of the 4-phenylazophenyl methacrylate-containing block in the ionic liquid is altered by irradiation with UV light. The phase behavior is monitored by small amplitude oscillatory shear rheology under either UV or visible light, and the ordered phases identified by small angle X-ray scattering. Understanding the phase behavior of this model system allows us to work towards inducing morphology changes in a contactless manner.
11:51AM G32.00004: Exploring the Limits of Actuation Force Output of Stretch-based Deformation of Liquid Crystalline Elastomers*  JOSELLE MCCRAKEN (Presenter), KELSEY M LYNCH, TIMOTHY J WHITE, University of Colorado, Boulder — Liquid crystal elastomer (LCE) films are amenable to surface-enforced alignment.[1] Physical limits of surface-enforced alignment constrain the thickness of LCEs aligned by this approach to a maximum of 50 µm.[2] The force output of stretch-based deformation of topologically patterned LCEs is enhanced with thickness, which we have previously accessed using a lamination approach for actuator fabrication.[3] This contribution details our exploration of the boundaries of achieving high force actuation from these soft materials. We describe several facile approaches for accessing thick LCE actuators (>30x a standard film), including the preparation of devices with interlaid compliant electrodes that allow rapid electrothermal deformation in the multi-laminate LCEs.

*DARPA-SHRIMP

12:03PM G32.00005: Electro-responsive Ionic Liquid Crystal Elastomers*  CHENRUN FENG (Presenter), Advanced Materials and Liquid Crystal Institute, Kent State University, CHATHURANGA PRAGEETH RAJAPAKSHA, VIKASH KAPHLE, BJORN LUSSEM, Department of Physics, Kent State University, THEIN KYU, Department of Polymer Engineering, University of Akron, ANTAL ISTVAN JAKLI, Advanced Materials and Liquid Crystal Institute, Kent State University — We will describe the preparation, physical properties and electric bending actuation of a new class of active materials - ionic liquid crystal elastomers (iLCEs). It is demonstrated that iLCEs can be actuated by low frequency AC or DC voltages of less than 1 V. The bending strains of the not optimized first iLCEs are already comparable to the well-developed ionic electroactive polymers (iEAPs). Additionally, iLCEs exhibit several novel and superior features, such as the alignment that increases the performance of actuation, the possibility of pre-programed actuation pattern at the level of cross-linking process, and dual (thermal and electric) actuations in hybrid samples. Since liquid crystal elastomers are also sensitive to magnetic fields, and can also be light sensitive, iLCEs have far-reaching potentials toward multi-responsive actuations that may have so far unmatched properties in soft robotics, sensing and biomedical applications.

*This work was financially supported by NSF DMR-1307674 and DMR-1502543.
Soft dielectric elastomers have aroused considerable interest in both research and industrial communities. Applications of elastomers include artificial muscle actuators, adaptive optics and energy harvesting. The basics of electro-elasticity have been highlighted by Toupin(1). We have modelled the behaviour of a soft deformable dielectric body under the combined effect of mechanical loading and electric field through non-linear finite element analysis. These materials are capable of large voltage-induced deformation, but achieving it in practice poses serious challenge due to electromechanical instability and electric breakdown. Our work is based on ideal dielectric elastomers. We precisely point out the extent of harnessing voltage-induced deformation in case of a soft cylindrical actuator and the suitable applications where such precise control is required. Additional results show an effective way of utilising the “snap through” phenomena in such actuators. The computations are carried out in Abaqus Software in conjunction with user-subroutine UEL in order to invoke the coupling effect in our problem. 

References:

Biomaterials find wide use in many branches of medicine and engineering. Success examples are hard biomaterials like titanium used in dentistry and prosthetics. Soft biomaterials, however, haven’t replicated these successes in repairing soft tissues. The reason is simple yet fundamental: existing soft biomaterials cannot match or integrate with soft tissues mechanically; they are often vulnerable to rupture and difficult to adhere on soft tissues, especially when interfacing with dynamic tissues such as skin and beating heart; their functionality is passive and limited. This talk will present new strategies and material systems to overcome these material constraints. A series of bioinspired hydrogel adhesives will be presented. One can be tougher than articular cartilage and achieve unprecedented adhesion performance on a variety of soft wet tissues, even under exposure of blood and dynamic movements [1]. The other can respond to the skin temperature, actively contract and heal skin wound effectively [2]. A mechanistic investigation with theoretical and computational mechanics approaches will be shown. This talk will also show how to realize spatiotemporal control of tissue adhesion on demand through controlling the surface and structure of the adhesive, and via external stimuli like ultrasound. This talk will highlight how to leverage a variety of physical, chemical and mechanical cues to finely tune the interactions between tissues and biomaterials to promote tissue repair and regeneration.

Flexoionic effect of Ionic Liquid Crystal Elastomers

CHATHURANGA PRAGEETH RAJAPAKSHA (Presenter), Department of Physics, Kent State University, CHENRUN FENG, Liquid Crystal Institute, Kent State University, CAMILO PIEDRAHITA, HAMAD ALBEHAIJAN, Department of Polymer Engineering, University of Akron, VIKASH KAPHLE, PUSHPA PAUDEL, BJORN LUSSEM, Department of Physics, Kent State University, THEIN KYU, Department of Polymer Engineering, University of Akron, ANTAL ISTVAN JAKLI, Department of Physics, Kent State University — Flexoelectricity (strain gradient induced electricity) has potential of a wide variety of applications such as strain sensors and micropower generators. Our present study was motivated by the novel phenomenon of mechanoelectrical conversion (flexoionic effect) of ionic electroactive polymers [1 ] and a new class of active material – ionic liquid crystal elastomers (iLCEs) [2]. Here we report the flexoionic effect of iLCEs. Highly ionic conductive iLCEs are prepared using M1 (4-(6-Acryloxy-hex-1-yl-oxy) phenyl-4-(hexyloxy) benzoate), M2 (1,4-Bis-[4-(6-acryloyloxyhexyloxy) benzoyloxy]-2-methylbenzene), ionic liquid (1-Hexyl-3-methylimidazolium hexafluorophosphate) and the photo initiator. The effect of alignment (planar, homeotropic and hybrid) and ionic liquid concentration at the function of bending amplitude are studied on the mechanoelectrical conversion.

Statistical field theory model for Liquid Crystal Elastomers

PRATIK KHANDAGALE (Presenter), KAUSHIK DAYAL, CARMEL MAJIDI, Carnegie Mellon Univ — Liquid Crystal Elastomers (LCEs) are composed of relatively stiff liquid crystal molecules connected with flexible polymeric chains. LCEs show fast reversible shape change with temperature because of nematic-isotropic phase transition of the liquid crystals. Thus, LCEs have promising applications as thermally active soft actuators, shape memory material and artificial muscles.

Existing models for LCE response are typically based on continuum mesoscale approaches such as phase field methods. While these models provide macroscopic predictive capability once material constants are calibrated, they are unable to predict mesoscale structure and response. In particular, these methods are unable to provide insight into the behavior of LCE composites composed of active components such as liquid metals or carbon nanotubes.

We develop a statistical mechanics-based field theoretic model for LCE response to enable us to probe these questions. The polymer chain elasticity is entropic while the liquid crystalline free energy is based on the Maier-Saupe mean field theory for liquid crystals. The model is solved numerically using a finite element approach. We extend this to the many-chain setting and examine the effects of temperature, geometry and loading conditions.
1:27PM G32.00010: Branching out and back: Reconfigurable nematic drops driven by molecular heterogeneity*  
WEI-SHAO WEI (Presenter), Department of Physics and Astronomy & LRSM, University of Pennsylvania, YU XIA, Department of Materials Science and Engineering, University of Pennsylvania, SOPHIE A ETTINGER, Department of Physics and Astronomy & LRSM, University of Pennsylvania, YUCHEN WANG, SHU YANG, Department of Materials Science and Engineering, University of Pennsylvania, ARJUN G YODH, Department of Physics and Astronomy & LRSM, University of Pennsylvania — Traditionally, polydispersity in matter is often avoided, since it tends to impede self-assembly and state transformation. Here we report reconfigurable nematic liquid crystal oligomer drops, which reveal, surprisingly, that molecular heterogeneity facilitates equilibrium transitions among dramatically different morphological structures, via spatial segregation. Specifically, fine-tuning the temperature and oligomer chain length distribution alters the balance between interfacial tension and liquid crystal elasticity, driving spontaneous formation of roughened spheres, flowers, and highly branched filamentous networks with uniform and controllable diameters. This feature provides potential connections to surface patterning in biological world, such as pollen grains. Further, we employ the achieved structures to template assembly of plasmonic nanoparticles, as well as helical coils with chiral dopant. With the capabilities of being produced reversibly and permanently locked into liquid crystal elastomers, the demonstrated simple rules thus offer new routes for programmed spatio-temporal networks.

1:39PM G32.00011: Imaging crack propagation in tough model gels by ultrasound elastography*  
HEIVA LE BLAY (Presenter), THOMAS DEFFIEUX, MICKAEL TANTER, ALBA MARCELLAN, ESPCI Paris — Assessing biomechanical properties of soft tissues by ultrasound imaging is still a challenge to help physicians to characterize pathologies. Benefiting from the recent progress in the field, the idea is to develop a novel, non-invasive tool with a high time-resolution to understand crack propagation processes in synthetic model gels. This approach offers new insights into soft matter fracture. This project focuses on the use of shear wave elastography for a local elasticity mapping at the vicinity of an advancing crack. Model polymer networks with well-controlled mechanical responses are synthetized following the protocol of Rose et al.[1]. By addition of silica nanoparticles (NPs), these gels combine a covalent polymer network (elasticity) with physical interactions by adsorption of polymer onto silica NPs (viscoelasticity) [2]. The gels are characterized in a wide range of frequencies in tensile mode (small strain rates) coupled with high frequency shear wave spectroscopy described by Deffieux et al.[3].

1:51PM G32.00012: Photoisomerization in a Glassy Matrix: Predicting a Broad Distribution of Dynamics with Machine Learning
KENNETH SALERNO (Presenter), TIMOTHY W SIRK, US Army Res Dev & Eng Command, JUAN DE PABLO, Pritzker School of Molecular Engineering, University of Chicago —

The response of azo-containing molecules undergoing a trans → cis photoisomerization transition has been primarily studied through simulation and experiment in solution or vacuum. The response of these photoactive molecules in glassy solids, where barriers to motion are significantly higher, is poorly characterized. Results from molecular dynamics simulations show that the dynamics of photoactivated molecules in glassy solids depends critically on local density features. A characteristic power-law wait time for photoisomerization occurs in samples for densities that vary with photoactive molecule and glass-matrix material. Dynamic behavior is driven by difficult-to-identify local density features, which suggests an opportunity for a machine-learning approach. We apply methods from structural analysis of an ideal disordered solid [1] to an all-atom molecular system for the first time, predicting a propensity to isomerize as an analog to “softness.” Our results not only demonstrate that simple machine learning methods can be applied to complex, all-atom molecular systems, but also highlight predictive features of local environments far beyond simple scalar quantities or visually identified features.

2:03PM G32.00013: Response of Polymer Conformations to Crowded Environments
KURT VANDONSELAAR (Presenter), MATTHEW KURTTI, ALAN DENTON, North Dakota State Univ —

Quantifying the effects of macromolecular crowding on conformations of polymers is important for understanding the structure and function of macromolecules in cellular environments, e.g., biochemical reactions between biopolymers. To efficiently study conformations of crowded polymers in good solvents, we adopt a coarse-grained model of a polymer as a penetrable ellipsoid whose size and shape fluctuate according to the statistics of a self-avoiding walk [1]. We model the crowders as spherical particles that interact via Lennard-Jones or Yukawa pair potentials with hard cores that can penetrate the polymer at a cost in entropy predicted by polymer field theory. To compute the polymer shape distribution, radius of gyration, and asphericity, we perform Monte Carlo simulations, including trial displacements and trial changes in polymer conformation. By varying interactions between crowders, we find that with increasing strength of attraction, the polymer geometric properties settle towards their uncrowded limits as a result of clustering of the crowders. These results may offer insight into reaction rates and functions of folded proteins within cells.

11:15AM G33.00001: Silicone-Iron Oxide Nanocomposite Encapsulants for Common Mode Noise Reduction in Switching Power Electronics*  HAYDEN CARLTON (Presenter), REECE WHITT, AMOL DESHPANDE, SARAH MYANE, NOAH AKEY, DAVID HUITINK, Univ of Arkansas-Fayetteville — The use of polymer encapsulants continues to permeate the electronics industry as a way to improve the reliability of packaging solutions, and the incorporation of nanomaterials presents an area of potential advancement. Management of electromagnetic noise represents a design challenge in power electronics that can be aided through the use of nanoparticle-enhanced encapsulants. Aluminum heat sinks often create common mode noise from AC disturbances generated by switching power supplies. Mitigation of this noise in modern electronics results in large increases in device efficiency; nanoparticles which have an intrinsic susceptibility to electromagnetic fields could add another dimension to encapsulant functionality by improving noise shielding. In the study presented herein, iron oxide nanoparticles were incorporated into a silicone rubber matrix to create an electromagnetically-susceptible nanocomposite in an effort to reduce common mode noise. After applying the nanocomposites to a prototype heat sink, a noticeable reduction in common mode noise was observed with just a relatively small amount of nanomaterial. Introducing this simple concept to modern designs will aid in improving noise management in power electronics devices.

11:27AM G33.00002: Flexible Textured Nanocomposite for Energy Harvesting Applications  VINEY GHAI (Presenter), HARPREEET SINGH, PRABHAT K AGNIHOTRI, Mechanical Engineering, Indian Institute of Technology Ropar — The present study provides a method for designing and fabricating a multifunctional flexible absorber (flexorb) that can be used as a coating material for ultra-high absorption applications. Untextured nanocomposite (UNC) is synthesized by reinforcing 1 wt. % of nanofillers [carbon nanotubes (CNTs), zinc oxide nanorods and iron nanoparticles] in polydimethylsiloxane (PDMS). Homogeneous mixture of these nanoparticles led to an ultra-high absorption ≥ 96 % from 300-2000 nm. Subsequently, texturing on the surface of UNC, enhance the absorption ≥ 99 % in entire UV-Vis-NIR wavelength range. This increase in absorption is due to the multiple scattering of incident beam along with the surface texture. In addition to this CNTs reinforced in flexorb provides better impedance matching which results in lower reflection losses from flexorb/air interface. Moreover, the textured nanocomposite exhibited a better tensile, tear, shear and peel-off strength than pure PDMS and UNC. The flexorb has an advantage of flexibility which ensures that it can be deformed in variety of shapes without any damage or creasing failure. Such a ultra-black textured nanocomposite may find many applications such as suppression of stray light in telescopes, thermal imaging sensors, spectroscopy and energy harvesting.
11:39AM G33.00003: Nanoparticle Assembly Modulated by Biobased Polymers and Its Coating Application* EMILY OLSON, YIFAN LI, FANG-YI LIN, ANA MILLER, FEI LIU, AYUNA TSYRENOVA, GREG CURTZWILER, KEITH VORST, ERIC COCHRAN, SHAN JIANG (Presenter), Iowa State University — We study how nanoparticles assemble in a dried film containing biobased polymers. Different nanoparticles were dispersed with hydroxyethyl cellulose (HEC) and hydroxyethyl starch (HES). It was discovered that polymer morphology has a profound influence on the assembly structures of nanocomposite. In addition, an unexpected highly fractal network structure assembled by nanoparticles were formed in HEC matrix with different types of nanoparticles. Electron microscopy and small X-ray scattering offer the detailed analysis of the structures. Based on these results, we further developed a biobased waterborne coating system to effectively block the UV radiation while maintaining the transparency using ZnO nanoparticles. Our new coating materials can lead to coating films ~ 100 times thinner than the previously reported coating systems of similar UV-blocking performance. The same concept can be applied to other polymer nanocomposite systems. The study opens the opportunity of utilizing more sustainable biobased materials for high-value functional coating applications.

*We thank NSF I/UCRC The Center for Bioplastics and Biocomposites (CB²), polymer and food protection consortium, USDA NIFA grant no. 2019-67013-29016 and NSF-DMR-1626315.

11:51AM G33.00004: Coarse-grained molecular dynamics simulations on mechanical properties of polymer composites for bulk heterojunction solar cells YUTA YOSHIMOTO (Presenter), SOU SUGIYAMA, TOSHIHIRO KANEKO, SHU TAKAGI, IKUYA KINEFUCHI, Univ of Tokyo — We investigate mechanical properties of polymer composites of poly(3-hexylthiophene) (P3HT) and fullerene C_{60} using coarse-grained molecular dynamics (CGMD) simulations, where the P3HT monomer unit and C_{60} are represented by three CG beads and a single CG bead. Pure P3HTs with the degrees of polymerization (DPs) of 50, 100, and 150 exhibit almost identical tensile moduli, while the tensile strength increases with the DP. We quantify an increase in the number of molecular chain entanglements resulting from increasing DP, which in turn enhances the tensile strength. Meanwhile, the decomposition of molecular interactions contributing to stress indicates that the tensile modulus is primarily determined by non-bonded potentials and bond length potentials, almost independent of the chain entanglements. Furthermore, the addition of C_{60} leads to higher tensile modulus and hence more brittle behavior of the composite in accordance with experiments. We find that an increase in C_{60} mass fraction further inhibits molecular chain entanglements, leading to a significant reduction of the tensile strength. Meanwhile, an increase in the tensile modulus mainly originates from an increase in non-bonded interactions associated with C_{60}. 
12:03PM G33.00005: Nanoparticle Templating of Ultrathin and High Density 6 nm Pore Arrays* GRAYSON JACKSON (Presenter), University of Chicago, XIAO-MIN LIN, Argonne National Laboratory, HEINRICH M. JAEGER, University of Chicago — Active layers for next-generation water filtration membranes require large area and uniform arrays of nanometer-sized pores. We demonstrate an alignment-free method to transform freely suspended nanoparticle (NP) monolayer sheets into mechanically robust, high density 6 nm pore arrays using electron beam irradiation and subsequent wet chemical etching. As the secondary electrons responsible for ligand crosslinking originate from the NPs themselves, our substrate-free approach benefits from a variable crosslink density throughout the ~10 nm film thickness. We apply this general strategy to two NP systems—gold NPs with alkanethiol ligands and Fe₃O₄ NPs coated with oleic acid—to fabricate nanostructured polymer films with either thiol or carboxylate pore chemical functionalities.

*We acknowledge support from the Office of Naval Research under grant ONR N00014-17-1-2342.

12:15PM G33.00006: Gas Transport of Self-assembled Polymer Nanocomposites with Binary Nanoparticle Size* SOPHIA CHAN (Presenter), MAYANK JHALARIA, ANDREW JIMENEZ, SEBASTIAN T RUSSELL, Chemical Engineering, Columbia University, BRIAN C BENICEWICZ, Chemistry and Biochemistry, University of South Carolina, SANAT KUMAR, Chemical Engineering, Columbia University — Covalently grafting organic (hydrophobic) polymer chains to inorganic (hydrophilic) nanoparticles is a facile means of addressing their inherent immiscibility. We have previously shown that membranes comprised of such grafted nanoparticles (GNPs) exhibit remarkable increases in gas permeabilities relative to that of the neat polymer. Here, we go beyond these previous works and combine GNPs of two different core sizes (14 nm and 50 nm) to probe the role of NP size polydispersity on NP structuring and therefore properties. Structurally, we find that the GNPs form self-assembled structures that fill space. We present the self-assembled morphologies and measured gas transport properties of these polymer nanocomposites with binary core sizes.

12:27PM G33.00007: Polymer Composites of Two-Dimensional Layered Materials for Structural Applications*
SEHMUS OZDEN (Presenter), 1) Princeton Institute for the Science and Technology of Materials; 2) Department of Chemical and Biological Engineering; 3) Department of Mechanical and Aerospace Engineering, NIKITA S. DUTTA, KATELYN RANDAZZO, CRAIG ARNOLD, RODNEY PRIESTLEY, Princeton University — Polymer composites of two-dimensional (2D) layered nanostructures such as graphene, graphene oxide (GO) and h-BN have promising potential in future technologies. However, although it has been more than a decade polymer composites of 2D-layered materials have been investigated, still fundamental challenges remain for practical applications. Currently, poor load transfer, good interfacial engineering and dispersion of layered materials in polymer matrix remain as a big challenge that needs to be overcome for the commercialization of these materials. 2D-layered materials offer significant advantages for developing thermally stable with robust mechanical properties, high electrical and thermal conductivities toward building ultra-lightweight multifunctional composites. Here, we report the development of highly porous, ultralight-weight and flexible polymer composite of 2D-layered structures for high temperature environmental applications. Physical, chemical and interfacial interactions of various polymer and 2D-layered structures will be discussed with the support of fully atomistic reactive molecular dynamics simulations that discloses unusual interface interactions between polymer matrix and 2D-layered structures.

*Princeton Center For Complex Materials Post-Doctoral Fellowship

12:39PM G33.00008: Mesostructured Metal Superconductors via Block Copolymer Nanocomposites: Quantum Metamaterials from Soft Matter*
RANDAL THEDFORD (Presenter), SOL MICHAEL GRUNER, ULRICH WIESNER, Cornell University — Three-dimensionally mesostructured superconductors have unique properties compared to thin film or bulk analogues, but their investigation has been limited by the lack of facile synthesis methods. Though largely unexplored in this application, block copolymers (BCPs) can serve as structure-directing agents to tune material architectures and, by extension, properties over scales on the order of characteristic lengths in superconductors (10s of nm). Hybrid BCP-inorganic self-assembly provides a route to mesostructured NbN superconductors, but complex materials chemistry prevents comparison with bulk equivalents. In recent work we demonstrate a versatile approach to mesoscale ordered metal superconductors via self-assembly of BCP nanocomposites. Results indicate quantum metamaterials behavior, with evidence that properties such as the transition temperature, coherence length, and critical field change substantially in a 3D periodic mesostructure (e.g., the bicontinuous double gyroid). Future work will investigate emergent phenomena such as angle-dependent magnetization behavior, and expansion of our technique to other metals could lead to novel photonic, electronic, and/or catalytic properties.

*R.P.T. supported by NSF GRFP (DGE-1650441)
12:51PM G33.00009: Experiments and Simulations of Nanoplate String Assembly in Lamellar Diblock Copolymer*  RUSSELL COMPOSTO (Presenter), NADIA KROOK, CHRISTIAN TABEDZKI, University of Pennsylvania, KEVIN YAGER, Brookhaven National Laboratory, KATHERINE ELBERT, CHRISTOPHER B MURRAY, ROBERT RIGGLEMAN, University of Pennsylvania — Within poly(styrene-b-methyl methacrylate) (PS-b-PMMA) block copolymer (BCP) lamellae, oriented nanoplates grafted with polyethylene glycol assemble into aligned strings at small interparticle separations. These assemblies are studied using X-ray scattering, electron microscopy, and hybrid particle/self-consistent field theory (hSCFT) simulations. The insertion of a nanoplate in a BCP microdomain is expected to produce a local domain bulge as the PS/PMMA interface distorts to optimize conformational chain entropy. 2D simulations of the equilibrium BCP structure show bulge formation around the nanoplates. As a function of particle separation, the potential of mean force (PMF) reveals a global minimum corresponding to an interparticle spacing of 7.0 nm, in good agreement with experimentals, 6.42 nm. The PMF calculation exhibits an activation barrier due to the high curvature penalty between two nanoplates at a separation of 21.7 nm. Ultimately, nanoplate strings form to optimize free energy contributions from interfacial area and chain stretching. The effect of BCP molecular weight on the PMF will also be presented.

1:03PM G33.00010: Molecular engineering of graft and matrix polymers for tuning grafted particle dispersion in polymer nanocomposites: A theory and simulation study*  ARJITA KULSHRESHTHA (Presenter), ARTHI JAYARAMAN, Univ of Delaware — In polymer nanocomposites (PNCs) comprised of grafted nanoparticles in a polymer matrix, tailoring the graft and matrix polymers is a way to tune the effective inter-particle interactions and morphology. In this talk we present our work using molecular simulations and theory showing how increasingly attractive graft-matrix interactions affect the interpenetration of matrix and graft chains (termed as grafted layer wetting) and the dispersion/aggregation of grafted particles in the matrix. Past work by our group on similar systems has shown that wetting/dewetting and dispersion/aggregation are two distinct phase transitions, former a continuous one and the latter a first-order transition as a function of graft-matrix interactions. In this work we find that as the graft-matrix attraction increases, the graft chains extend and matrix chains increasingly wet the grafted layer, leading to larger and harder grafted particles compared to analogous PNCs with athermal graft-matrix interactions. Simultaneously, the PNC structure changes from an aggregated/dispersed morphology dictated by the entropic limit to a dispersed morphology due to favorable weak graft-matrix attraction, and finally, to a correlated fluid of hard grafted particles at stronger graft-matrix attraction.

*DOE #DE-SC0017753
1:15PM G33.00011: Polymer grafted nanoparticles on Polymer Films: Entropic and Enthalpic effects on strcture and dynamics*  JAYDEEP BASU (Presenter), NIMMI DAS ANTHUPARAMBIL, APARNA SWAIN, Indian Institute of Science — Nanoparticle based ultra-thin membranes have been shown to have remarkable mechanical properties while also possessing novel electrical, optical or magnetic properties, which could be controlled by tailoring properties at the level of individual nanoparticles. Here we report thermal stability and the corresponding microscopic dynamics of polymer supported ultra-thin membranes comprising of self-assembled, ordered grains of polymer grafted nanoparticles having tunable mechanical properties. The initially ordered membranes show distinct pathways for temperature induced disordering depending on membrane flexibility as well as on interfacial entropic and enthalpic interactions with the underlying polymer thin film. We also observe contrasting temperature dependence of microscopic dynamics of these membranes depending on whether the graft polymer-substrate polymer interactions are predominantly entropic or enthalpic in nature. Our results suggest that apart from their varied applications, the soft nanoparticle-polymer hybrid membranes are a playground for rich physics involving subtle entropic and enthalpic effects along with the nanoparticles softness, which eventually determine their thermo-mechanical stability

1:27PM G33.00012: Gradient-Based Explicit Theoretical Framework for Simulation of Block Copolymer-Nanoparticle Co-assembly  DANIIL BOCHKOV (Presenter), FREDERIC GIBOU, University of California, Santa Barbara — The co-assembly of dispersed nanoparticles in block copolymers is a promising avenue for creating ordered structures at the nanoscale and materials with unique properties. Consequently, the theoretical understanding of this phenomenon is of great interest. In this talk, we present a novel theoretical framework for the simulation of the block copolymer-nanoparticle co-assembly. In this approach, we explicitly keep track of each particle in a sharp fashion while describing the polymer material using the Self-Consistent Field Theory. We consider particles of arbitrary shapes and allow the particle's surface affinity for different polymer components to be variable in space. The relaxation of block copolymer-nanoparticle mixtures to (meta) stable configurations is performed using a gradient-type approach based on the analytically derived expression for the virtual work of nanoparticles or, in other words, the full derivative of the system's energy with respect to the particles's orientations and positions. We provide several benchmark examples to demonstrate the capabilities of the proposed framework.
1:39PM G33.00013: Relating Entanglements and Toughness in Model Polymer-Grafted Nanoparticles  [Invited]  LISA HALL (Presenter), Ohio State Univ - Columbus — Polymer-grafted nanoparticles (PGNs) are a means to create precisely structured inorganic-organic hybrid materials. The graft length and graft density are key parameters that control interparticle spacing and other structural and mechanical properties. To guide materials design, we use coarse-grained molecular dynamics (MD) simulations to relate these parameters to structure, entanglements, and mechanical properties. We consider moderate to high graft density PGNs, which do not have large bare surface regions and are stable in the melt state in a hexagonally packed monolayer on a smooth attractive surface. As intuitively expected, grafts on adjacent PGNs are more interpenetrated in lower graft density systems. We define the interparticle entanglements (involving grafts originating from two different particles) and analyze these using both a topological and a time averaging method. We find that lower graft density (increased interpenetration) leads to increased interparticle entanglements per chain and increased toughness in both the melt and glassy state. The relationship between entanglement type and location and toughness will also be discussed.

Session G34 DPOLY DBIO DCOMP: Machine Learning and Data in Polymer Physics II  506 - Tyler Martin, National Institute of Standards and Technology - Tag(s): Focus

11:15AM G34.00001: Machine Learning and Data in Polymer Physics Research - Interpretation of Experiments, Model Development, and Enhanced Sampling  [Invited]  JUAN DE PABLO (Presenter), University of Chicago — Advances in molecular modeling algorithms, optimization strategies, and machine learning techniques, are ushering a new era of materials science and engineering in which computational tools are routinely used to probe, design, and interrogate matter and functional materials systems. The way in which problems and questions are formulated is rapidly changing, and it is important to rethink the role of research scientists and engineers in the context of these advances. In this presentation I will illustrate some of these ideas by relying on a variety of examples taken from polymer physics. In the first, I will discuss the coupling of experiments and molecular models, and how that coupling can be used to extract additional information from experiments that would otherwise be difficult to generate. In the second I will present models of biological systems – DNA and chromatin - that use machine learning to integrate experimental and computational information form a wide range of sources, and explain how the resulting information can be used to address important questions in epigenetics. In the third, I will discuss how machine learning can be used to design polymer structures or architectures for specific target properties.
11:51AM G34.00002: Neural Network Accelerated Self-Consistent Field Theory  HEJIN HUANG, Materials Science and Engineering, Massachusetts Institute of Technology MIT, KARIM GADELRAH, Bosch USA, ALFREDO ALEXANDER-KATZ (Presenter), Materials Science and Engineering, Massachusetts Institute of Technology MIT — Self-consistent field theory (SCFT) has demonstrated excellent capabilities in predicting self-assembled structures of block copolymers (BCP) at equilibrium. This method has been widely implemented in BCP self-assembly to understand its assembly process. Although SCFT gives accurate results, it is a relatively time-consuming method: SCFT involves solving differential equation numerically in matrix form at each time step and normally takes thousands of steps to reach the final structure at equilibrium, which makes it difficult to be applied to large 3D systems. In this work, we train a neural network (NN) to predict the evolving field during SCFT free energy minimization. After training the NN, we implement a hybrid algorithm combining SCFT with the trained NN. This NN-SCFT model helps to shorten the SCFT simulation time significantly (approximately x10 speedup), with convergence being achieved in all different cases (different volume ratio, and the chemical incompatibility between blocks). The NN-SCFT hybrid system, thus, provides a powerful tool for further exploration of larger BCP directed self-assembly systems and inverse self-assembly.

12:03PM G34.00003: Neural network for phase diagrams of polymer-containing liquid mixtures*  ISSEI NAKAMURA (Presenter), Physics, Michigan Technological Univ — We develop deep neural networks (DNNs) that consider the phase separation of polymeric liquids. In this talk, we discuss our new hidden layer that is constructed through coarse-grained mean-field theory and the scaling laws in polymer physics. This characteristic hidden layer enables us to perform the learning process efficiently with relatively small numbers of artificial neurons and hidden layers and provides the DNNs with reasonable predictive power. To demonstrate the efficacy of our DNNs, we will discuss the phase diagrams of polymer solutions, and the salt-free and salt-doped diblock copolymer melts. Moreover, we will show the predictive power of the DNNs by considering some experiments for the lithium salt-doped diblock copolymers such as PEO-b-PS.

Predicting the glass transition behaviors of polymers via integration of molecular simulations, theory, and machine learning

WENJIE XIA (Presenter), AMIRHADI ALESADI, North Dakota State Univ — Understanding and predicting the glass transition behavior of glass-forming polymers are of critical importance from both physical and practical standpoints. The substantial change in polymer relaxation and dynamics upon cooling causes major change in most physical properties, including mechanical modulus, density, specific heat, damping characteristics, dielectric properties of a polymer. The cheminformatics-based approach based on machine learning (ML) algorithms is often applied to draw the quantitative relationships between key molecular parameters/descriptors and properties of polymers. In this work, we develop an innovative framework by integrating cheminformatics and coarse-grained molecular dynamics (MD) simulations to predict the glass transition temperature of diverse sets of hundred polymers. Moreover, the use of generalized entropy theory in conjunction with ML uncovers the critical roles of key molecular parameters (i.e., cohesive interactions, chain stiffness, and branching) in influencing the glass transition temperature as well as other characteristic temperatures associated with glass formation of polymers.

Extracting molecular mechanisms of shear-thinning of liquids at high strain rates using machine learning*

VIKRAM JADHAO (Presenter), JCS KADUPITIYA, Intelligent Systems Engineering, Indiana Univ - Bloomington — Recent nonequilibrium molecular dynamics simulations have shown that shear-thinning of molecular liquids such as squalane at high strain rates (over 10^5 per second) exhibit a transition from a low-Newtonian-viscosity regime described well by power-law models to a high-Newtonian-viscosity regime where the flow properties are consistent with thermally-activated flow models. This talk explores the use of machine learning to probe the molecular origins of this rheological transition. Molecular trajectory data from simulations of small-molecular liquids sheared over a broad range of pressures and rates are used to design a 3D feature matrix. Using this matrix as input, several linear and nonlinear dimension reduction techniques are used to reduce the dimensionality of the feature space. We find that t-distributed stochastic neighbor embedding (t-SNE) can rapidly and effectively cluster trajectory data enabling the identification of molecular features (sets of atom pairs) diagnostic of the evolution in molecular order. Subsequent calculations of the order parameter and its linking with macroscopic rheological properties enable the determination of the amount of shear-thinning that comes from the evolution in order.

*This work is supported by Indiana University startup funds.
12:39PM G34.00006: Hybrid machine learning/materials science modeling for semi-crystalline polymer during film fabrication process  JIAN YANG (Presenter), TERESA KARJALA, JONATHAN MENDENHALL, VALERIY GINZBURG, RAJEN PATEL, FAWZI HAMAD, ELVA LUGO, PAVAN VALAVALA, The Dow Chemical Company — For semi-crystalline polymer like polyethylene (PE), it is well known that PE film physical properties is heavily dependent on the morphology of both the crystalline phase and amorphous chains, which can be largely influence by the film processing conditions. A clear understanding of the relationships of polymer molecular fingerprint, formulation, fabrication conditions and physical properties is important for future materials design, which can be traced back to polymerization process. However, this is generally considered to be a very complicated problem due to the large parameter space. In this report, we developed a new hybrid approach to combine the power of machine learning and fundamental materials science to characterize semi-crystalline PE, develop structure-property relationship and study the effect of fabrication conditions on physical properties during blown film fabrication process and to inform the design of new polymer structures.

12:51PM G34.00007: Developing Databases for Polymer Informatics  ROSELYNE TCHOUA, DePaul University, ZHI HONG, University of Chicago, DEBRA AUDUS (Presenter), National Institute of Standards and Technology, SHRAYESH PATEL, LOGAN WARD, KYLE CHARD, JUAN DE PABLO, IAN FOSTER, University of Chicago — One significant barrier to the adoption of polymer informatics is a lack of large FAIR (Findable, Accessible, Interoperable, Reusable) databases. In an effort to overcome this barrier, we developed pipelines to harness the vast quantities of valuable experimental polymer data trapped in the literature. In our first effort, we developed the largest Flory-Huggins chi parameter database using crowdsourcing and found that the burden to review papers could be lessened by training a classifier to identify promising articles. To further reduce human input, we turned to natural language processing software coupled with specially designed software modules to extract glass transition temperatures with minimal human input; ultimately, we extracted over 250 glass transition temperatures. All of the resulting data is freely available at the Polymer Property Predictor and Database website (http://pppdb.uchicago.edu). During this process, we found that identification of the polymer names within the literature was a key problem as polymers are referred to by common names, sample names, labels, etc. and subsequently explored named entity recognition to tackle this problem. To further extend our databases, we are working on allowing them to accept user submitted data.
As a powerful example of how machine learning (ML) algorithms can streamline discovery from experimental data, scientists at the LBNL Advanced Light Source have employed Convolutional Neural Networks (CNN) [1, 2] to enable lattice structure classification using diffraction patterns, and Gaussian process regression to construct surrogate models and error functions based on the limited experimental data. Diffraction patterns have come from Grazing Incidence Small Angle X-ray Scattering (GISAXS), a surface sensitive technique with increasingly usage growth in probing complex morphologies, such as conductive polymers. GISAXS allows electron density correlation analyses at surfaces by combining features from small-angle X-ray scattering and diffuse X-ray reflectivity. Resulting scattering patterns work as signatures, which depend on the size, shape, and arrangement of the nano-structured components. We will illustrate some of the advantages of using ML methods over traditional ways of searching for configurations in large materials databases. We will also discuss scaling analysis to high-throughput data to enable quick selection of materials, and benefits of autonomous experiments [3], faster experimental sessions and accelerated scientific discovery from materials science samples.

1:39PM G34.00009: Parameter Estimation for Spatio-Temporal Models using Bayesian Optimisation and Gaussian Processes* NIGEL CLARKE (Presenter), Department of Physics and Astronomy, University of Sheffield, JOAO CABRAL, Department of Chemical Engineering, Imperial College, RICHARD WILKINSON, School of Mathematics and Statistics, University of Sheffield, WIL WARD, Department of Physics and Astronomy, University of Sheffield, SEBASTIAN PONT, Department of Chemical Engineering, Imperial College — With many physical models having only numerical solutions, it can be challenging to fit predictions to data. We show how accurate joint estimation of parameters can be achieved efficiently with Bayesian optimization and Gaussian processes, even for spatio-temporal models, using the Cahn-Hilliard equation of phase separation as an exemplar.

To find globally optimal parameters, we represent the distance between the results of simulation and some observed outcome using a loss function. Instead of a computationally expensive grid-based search for the minimum loss, we adopt a Bayesian optimisation approach placing a Gaussian process over the loss, representing the function as an infinite-dimensional normal distribution that can be used to estimate it over its entire input space, with quantified uncertainty. The GP can be trained using a small number of evaluations, and a suggestion for the next test-point can be obtained automatically. New evaluations are used to update the GP estimation. Bayesian optimisation has the ability to localise regions where minima occur within a small number of iterations. The intrinsic incorporation of uncertainty allows for an effective trade-off between this exploitation and exploration of the wider input space.

1:51PM G34.00010: Evolutionary couplings detect side-chain interactions in protein structures* ADAM J. HOCKENBERRY, CLAUS WILKE (Presenter), University of Texas at Austin — Patterns of amino acid covariation in large protein sequence alignments can inform the prediction of de novo protein structures, binding interfaces, and mutational effects. While algorithms that detect these so-called evolutionary couplings between residues have proven useful for practical applications, less is known about how and why these methods perform so well, and what insights into biological processes can be gained from their application. Here, we show that evolutionary coupling analyses are significantly more likely to identify structural contacts between side-chain atoms than between backbone atoms. We use both simulations and empirical analyses to highlight that purely backbone-based definitions of true residue–residue contacts may underestimate the accuracy of evolutionary coupling algorithms by as much as 40% and that a commonly used reference point (Cβ atoms) underestimates the accuracy by 10–15%. These findings show that co-evolutionary outcomes differ according to which atoms participate in residue–residue interactions and suggest that accounting for different interaction types may lead to further improvements to contact-prediction methods.

2:03PM G34.00011: Tracking Accelerated Aging of Cross-Linked Polyethylene Pipes by Applying Machine Learning Concepts to Infrared Spectra  MELANIE HILES, JOSEPH D’AMICO (Presenter), BENJAMIN MORLING, FATEMEH ABBASI, MICHAEL GROSSUTTI, JOHN DUTCHER, Univ of Guelph — Cross-linked polyethylene (PEX) pipes are promising replacements for metal or concrete pipes used for water, gas and sewage transport. Characterizing changes to the polymer and additive compounds with in-service use is paramount to predicting pipe failure. Infrared (IR) microscopy combines the chemical specificity of IR spectroscopy with the high spatial resolution of light microscopy, and we have used this technique to track variations in the degree of crystallinity and additive concentration across the wall thickness of PEX pipes. We have shown that principal component analysis of IR absorbance peaks can be used to differentiate and classify different pipe formulations [1]. We have used this methodology to characterize changes to pipes that have been subjected to accelerated aging involving heating in water and air, and exposure to ultraviolet radiation. This has allowed us to identify and track IR peaks that are most relevant to pipe degradation. We have used these results, together with machine learning techniques, to identify and classify different modes of pipe degradation.

Tuesday, March 3, 2020 11:15 AM - 1:39 PM

Session G35 DPOLY: Padden Award Symposium

11:15AM G35.00001: Photo-induced Melting of Semi-Crystalline Polymers via Azobenzene Isomerization*  ALEXA KUENSTLER (Presenter), RYAN HAYWARD, University of of Massachusetts - Amherst — Incorporation of photo-isomerizable molecules into macromolecular systems is a powerful method to harness Angstrom-level geometry changes induced by light to drive macroscopic shape changes and force generation. The most commonly explored material platforms exploit azobenzene isomerization-driven disordering of nematic polymer networks. While these materials generally perform better than isotropic networks due to cooperative nanoscale organization, higher ordering of azo-molecules into crystalline lattices presents a potential route to further enhance photogenerated work output. To this end, we have explored semi-crystalline azo polymers as a means to enhance ordering while preserving the processability inherent to polymer systems. We show that upon UV light exposure these materials undergo an isothermal melting of crystalline lamellae due to trans-cis isomerization, and that crystalline order can be restored upon re-isomerization back to the trans state. Interestingly, this process is found to be strongly suppressed at temperatures sufficiently far below the melting point. Finally, using shear alignment, we demonstrate the fabrication of well-aligned crosslinked fibers wherein reversible and directional crystallization can be harnessed for photoactuation.

*ONR N00014-18-1- 2624
11:27AM G35.00002: Materials by design for hairy nanoparticle assemblies*  NITIN HANSOGE (Presenter), SINAN KETEN, Northwestern University — A computational framework that combines machine learning and coarse-grained molecular dynamics (CGMD) simulations to tailor the mechanical properties of hairy nanoparticle assemblies (aHNP) is proposed. CGMD informed metamodel on PMMA-grafted nanocellulose assemblies revealed the necessity of having relatively low grafting density, high molecular weight, and high nanoparticle loading on achieving Pareto optimality. Utilizing theoretical scaling relationships derived from Daoud–Cotton theory, we identified the critical length scale \(N_{cr}\) governing Pareto optimality, originating based on conformational transition from concentrated to semi-dilute brush regime. We verified this finding by expanding our analysis to other common polymers, and quantified the role of polymer chemistry, backbone rigidity and side-group size of a polymer on the chain conformations and \(N_{cr}\). Remarkably, normalization of the monomer radial distribution curves using \(N_{cr}\) and other key molecular parameters collapsed the curves for 110 distinct model aHNP systems to a universal curve governing the chain conformations in aHNPs. The novel modeling framework along with the new physical insights into the confinement and interface effects in aHNPs pave the way for superior designs of aHNPs.

*PECASE, Award #N00014163175

11:39AM G35.00003: Multiscale Polymer and Nanoparticle Dynamics in Attractive Polymer Nanocomposite Melts  ERIC BAILEY (Presenter), RUSSELL COMPOSTO, KAREN WINEY, University of Pennsylvania — The addition of nanoparticles (NPs) to a polymer matrix, forming a polymer nanocomposite (PNC), has been used to extend and control macroscopic material properties. Many macroscopic properties are dictated by microscopic dynamic processes, including the dynamics of the polymer segments, chains, and NPs, which remain poorly understood in PNCs. This work experimentally explores the hierarchy of dynamics in model PNC melts with poly(2-vinylpyridine) and attractive NP-polymer interactions. In PNCs with 26-nm diameter NPs, we show that a bound polymer layer forms in solution and persists to the melt state. Using various techniques, we report that segmental relaxations near the NP interface are slower than in neat polymer and lead to polymer chain desorption that is \(~10^4\) times slower than bulk diffusion. Interestingly, when the NP size is commensurate with the polymer segments (~2 nm), the dynamics are quite different. For example, polymer segments are slowed homogeneously, slow chain diffusion is quantitatively described by increased segmental friction, and the NPs diffuse anomalously fast. Overall, these results highlight the complex and synergistic effects of NPs and polymers in PNCs and provide insights to help design functional PNCs for a variety of applications.
Polymers under Extreme Nanoconfinement

HAONAN WANG (Presenter), YIWEI QIANG, JYO LYN HOR, AHMAD ARABI SHAMSABADI, University of Pennsylvania, PRANTIK MAZUMDER, Sullivan Park, Corning Incorporated, DAIEWSHON LEE, ZAHRA FAKHRAAI, University of Pennsylvania — Polymers under nanoconfinement can show significantly deviated properties from bulk. Capillary Rise Infiltration (CaRI) can produce extreme polymer confinement by infiltrating the polymer into densely-packed nanoparticle (NP) films. Here, we use CaRI films to study physical and chemical properties of polymers under extreme nanoconfinement, including glass transition temperature ($T_g$), fragility, and thermal degradation. Polystyrene(PS)/SiO$_2$ and Poly(2-vinylpyridine)(P2VP)/SiO$_2$ CaRI films were used as the model systems with weak and strong interfacial interactions. The degree of confinement was tuned by using polymers with different molecular weights and NPs with different sizes (forming pores with 3-30 nm average size). We show that $T_g$ can increase by ~57 K for PS and ~100 K for P2VP confined in 3 nm pores. Furthermore, P2VP in CaRI films shows broader glass transition width but slightly lower fragility than bulk, indicating the gradient of dynamics in the pores. The thermal stability of both polymers are significantly enhanced in CaRI films with less char formation. The details of the process shows that the activation energy of PS degradation can increase by ~50 kJ/mol under nanoconfinement.

Deformation response of a two-dimensional polymer

BEATRICE SOH (Presenter), PATRICK DOYLE, Massachusetts Institute of Technology MIT — Kinetoplast DNA is the mitochondrial DNA of trypanosomes and related parasites. A kinetoplast is a complex two-dimensional network of topologically interlinked circular DNA. There has been much interest in studying the kinetoplast from a microbiology point of view, but little is known about the material properties of the network structure. The stretching response of a one-dimensional linear polymer has been studied extensively using single-molecule experiments. In this work, we probe experimentally the deformation response of the kinetoplast as a model two-dimensional polymer. We subject kinetoplasts to planar elongational fields in microfluidic channels and study the dynamics of kinetoplasts under a constant strain rate, as well as the relaxation dynamics of kinetoplasts.
12:15PM G35.00006: Decoupling the role of entanglements and mobility in the mechanics of ultrathin polymer glasses

R. KONANE BAY (Presenter), ALFRED J CROSBY, Polymer Science and Engineering, University of Massachusetts Amherst — As polymer glasses are processed into ultrathin films, neighboring polymer chains become less entangled, and surface-bound chains with altered states of mobility play an increasingly important role. Such changes in physical properties have long been studied, but changes in mechanical strength and deformation processes have remained difficult to quantify. We have developed a method to directly measure the uniaxial stress-strain response of ultrathin glassy polymer films of both liquid supported and freestanding films. In our work, we quantify the influence of thickness (10nm - 360nm), and molecular weight (61kDa - 2135kDa) on the deformation and failure response of ultrathin polystyrene films. We observe a molecular weight independent thickness-transition in strain localization and elastic modulus, and a molecular weight dependent decrease in maximum stress. We associate the changes in strain localization and elastic modulus to the surface mobile layer, and we form a model to capture the role of the average molecule size and the number of entanglements per chain on the decrease in maximum stress. These results provide new fundamental insights into how polymer behavior is altered due to changes in the entanglements and mobility in a polymer network upon confinement.

12:27PM G35.00007: Influence of Polymer Polarity on Ion Transport in Polymer Electrolytes

BILL WHEATLE (Presenter), NATHANIEL A LYND, VENKATRAGHAVAN GANESAN, University of Texas at Austin — Polymer electrolytes are materials that could improve the safety and performance of lithium-ion and -metal batteries. Despite their promising attributes, such as high shear modulus and electrochemical stability, they tend to have sluggish ionic transport. Several properties have been shown to improve ionic transport, including host segmental dynamics. Recently, we showed that host polymer polarity, measured by the dielectric constant, is also an influencing factor in ionic transport. We found that higher polarity polymers more effectively break up ionic aggregates, which reduces correlated ionic motion. However, our study focused on polymers with a narrow dielectric constant range (~3–7), which prohibited a general understanding of the extent to which improving polarity could improve ionic transport.

In this work, we turn to a coarse-grained simulation model with which we explore a wide range of polymer polarities and simultaneously explore the influence of polymer molecular weight and salt concentration. We show that ionic transport maximizes at intermediate polarity due to a competition between reduced ionic aggregation and slowed polymer dynamics. We demonstrate that ionic transport only couples to molecular weight and salt concentration once a threshold polarity is exceeded.
**12:39PM G35.00008: Solvation-Site and Dielectric Control of Ion Conduction in Polymer Electrolytes**

NICOLE MICHENFELDER-SCHAUSER (Presenter), DOUGLAS GRZETIC, GLENN H FREDRICKSON, RAM SESHADRI, RACHEL A SEGALMAN, University of California, Santa Barbara — Solid polymer electrolytes have the promise of improving safety and performance in energy storage devices. Metal cation-containing polymers provide a path to effective electrolytes, with dynamic metal-ligand interactions allowing mechanical properties and ionic conductivity to be widely and separately tuned. A modular synthetic platform based on thiol-ene click chemistry is presented that allows polymers to be post-functionalized with a variety of metal-binding ligands. This well-controlled model system has enabled the study of factors known or suspected to influence ionic conductivity, including segmental dynamics, dielectric constant, solvation site density, and ligand identity. Design rules based on this model platform have been developed by combining experimental results with field-theory-based simulations. The results underscore that low dielectric constant is not necessarily detrimental to ionic conductivity, especially in systems where the resulting ion aggregates form percolating domains.

**12:51PM G35.00009: Self-assembly of Salt-Doped Ternary Polymer Blends**

SHUYI XIE (Presenter), TIMOTHY LODGE, University of Minnesota — Ternary polymer blends comprising A and B homopolymers and an A-B block copolymer can self-assemble into various microstructures, depending on the polymer composition, chain architecture and temperature. When doped with salt, such blends are promising for applications such as lithium ion batteries due to the tunable morphology. The addition of lithium bis(trifluoromethane)sulfonamide (LiTFSI) to a polymer blend system containing low molar mass poly(ethylene oxide) (PEO) and polystyrene (PS) homopolymers, and a PS–PEO block copolymer (SEO) induces either macroscopic or microscopic phase separation. Blends with different total homopolymer compositions (fH) and volume ratios of PEO and PS homopolymer (fPEO/fPS) at specific temperatures are investigated. In some regions of the phase prism, addition of salt recovers the microphase separated structures of conventional ternary blends, and in particular creates a wide bicontinuous microemulsion (BμE) channel. With still higher fH, a surprising C15 Laves phase is found. This work will help understand the self-assembly of ion-containing A/B/A-B ternary polymer blends and guide the experimental design of polyelectrolyte systems with tunable nanostructures.

1:03PM G35.00010: SANS Partial Structure Factor Analysis for Determining Protein-Polymer Interactions in Semidilute Solution* HELEN YAO (Presenter), AARON HUANG, BRADLEY OLSEN, Massachusetts Institute of Technology MIT — Protein-polymer interactions play a crucial role in many processes, including protein crystallization, biofouling, and self-assembly of protein-polymer bioconjugates. However, it is often difficult to measure these interactions in multicomponent systems, especially in semidilute solutions. Here, contrast-variation small-angle neutron scattering (CV-SANS) was used to quantify the interactions between three water-soluble polymers (PNIPAM, POEGA, and PDMAPS) and a model protein mCherry. CV-SANS enables decomposition of SANS intensities into partial structure factors that describe polymer-polymer, protein-protein, and polymer-protein interactions. The three polymers span various chemistries and properties, with PNIPAM and POEGA being non-ionic polymers with different hydrogen-bonding capabilities and PDMAPS being a zwitterionic polymer. PNIPAM/mCherry interactions were repulsive and dominated by depletion forces. In contrast, POEGA/mCherry interactions are attractive, with polymer enrichment at the protein surface. PDMAPS/mCherry interactions are more complex, with both depletion and electrostatic contributions. CV-SANS thus represents a powerful method to separate, quantify, and reveal the nature of interactions in multicomponent systems.

1:15PM G35.00011: Self-regulating metal cross-linked hydrogels via competition SETH CAZZELL (Presenter), NIELS HOLTEN-ANDERSEN, Massachusetts Institute of Technology MIT — Polymer networks with dynamic cross-links have generated widespread interest as tunable and responsive viscoelastic materials. However, narrow stoichiometric limits in cross-link compositions are typically imposed in the assembly of these materials to prevent excess free cross-linker from dissolving the resulting polymer networks. Using both computational and experimental methods, we demonstrate how the presence of molecular competition allows for vast expansion of the previously limited range of cross-linker concentrations that result in robust network assembly. Specifically, we use metal-coordinate cross-linked gels to verify that stoichiometric excessive metal ion cross-linker concentrations can still result in robust gelation when in the presence of free ion competing ligands, and we offer a theoretical framework to describe the coupled dynamic equilibria that result in this effect. We believe the insights presented here can be generally applied to advance engineering of the broadening class of polymer materials with dynamic cross-links.
1:27PM G35.00012: Deciphering Low-Temperature Dielectric Relaxation of a Series of Amorphous Polymers  DANIEL WILCOX (Presenter), GRIGORI MEDVEDEV, HOSUP SONG, JAMES M CARUTHERS, BRYAN BOUDOURIS, Purdue Univ — In contrast to the crystalline solid and gaseous phases, the physics behind the behavior of liquids and amorphous solids remains a significant challenge. Current descriptions of relaxation behavior in these materials are highly empirical, either utilizing fitting functions with tenuous physical significance, or fitting to a spectrum of Debye relaxation processes, where typical procedures implicitly make the unphysical assumption that the spectral density with respect to the characteristic times is constant and unvarying with temperature. Recently, we have found that the relaxation behavior of a moderately cross-linked epoxy resin is well described by a relaxation spectrum where the spectral strengths of individual components are constant while the spectral density is non-uniform and varies with temperature. The sub-Tg γ-relaxation is well described by a constant strength spectrum spanning over roughly 12 orders of magnitude in the frequency domain. In this work we use this newly developed approach to study the γ-relaxation of a series of epoxy resins with differing crosslink densities. From this, we develop maps showing the temperature dependence of the relaxation spectra, with which we aim to pinpoint the effect of crosslinking on the relaxation behavior of these materials.

Session G36 DBIO: Delbruck Prize Session 601/603 - Phil Nelson, University of Pennsylvania - Tag(s): Invited

11:15AM G36.00001: Synthetic Biology: Physical Biology by Design [invited]  JAMES COLLINS (Presenter), Massachusetts Institute of Technology MIT — Synthetic biology is bringing together physicists and biologists to model, design and construct biological circuits out of proteins, genes and other bits of DNA, and to use these circuits to rewire and reprogram organisms. These re-engineered organisms are going to change our lives in the coming years, leading to cheaper drugs, rapid diagnostic tests, and synthetic probiotics to treat infections and a range of complex diseases. In this talk, we highlight recent efforts to create synthetic gene networks and programmable cells, and discuss a variety of synthetic biology applications in biotechnology and biomedicine.
11:51AM G36.00002: Physical principles from evolutionary synthetic biology* [Invited]  GABOR BALAZSI (Presenter), State Univ of NY - Stony Brook — Synthetic biology designs and builds artificial biological systems, using principles from engineering, mathematics and physics. Just like engineering was crucial for many traditional physics discoveries over the past centuries, synthetic biology can advance biological physics by providing sensors, switches, oscillators, control knobs and other tools for quantitatively monitoring and perturbing living cells. Moreover, synthetic biological devices can serve as simple model systems to elucidate complex biophysical processes. For example, synthetic biological devices evolve along with the cells that carry them, providing new opportunities to investigate cellular and molecular evolution. I will present examples of how evolving synthetic gene circuits can provide deeper understanding of evolutionary processes, specifically of gene networks mediating the adaptation of cell populations.

*This research is supported by NIH/NIGMS MIRA grant R35 GM122561 and by the Laufer Center for Physical and Quantitative Biology.

12:27PM G36.00003: Synthetic Biology: Building to learn so that we might learn to build [Invited]  JEFF HASTY (Presenter), Univ. California San Diego — Synthetic Biology can be broadly parsed into the “top-down creation” of entire genomes and the “bottom-up engineering” of relatively small genetic circuits. A defining component of the gene circuit approach is the development of theory that can serve as the foundation for a new type of cellular engineering. This talk will be anchored by my quest to build genetic oscillators in cells, with a particular focus on the utility of mathematical modeling in determining general design principles. I'll first describe the design and construction of an intracellular circuit that cycles over a wide range of environmental conditions (http://biodynamics.ucsd.edu/Intracellular.mov). The large space of observed oscillatory behavior drove a revision of model equations that revealed unanticipated coupling of the clock to native cellular processes. More generally, the necessity of the model revision led to our ongoing exploration of biochemical networks that act as queues that can be balanced at a type of critical point. In terms of engineering, the clock was not of the Swiss variety; the period and amplitude exhibited large intracellular variability. However, viewed through the lens of dynamical systems theory, the noisy oscillator provided a benchmark for the development of general synchronization strategies that can restore determinism. This led to three studies describing (i) how quorum sensing can be used to couple clocks between cells (biodynamics.ucsd.edu/Intercellular.mov), (ii) how redox signaling can combine with quorum sensing to couple colonies at centimeter length scales (biodynamics.ucsd.edu/Intercolony.mov), and (iii) how intra- and inter-cellular dynamics can be rapidly coupled and used to encode information (biodynamics.ucsd.edu/Multiplexing.mp4). I'll conclude with a brief description of current applications that have arisen from our progress in traversing the scales from mathematical design in single cells to observable dynamics at the macroscopic level.
1:03PM G36.00004: Context dependence of biological circuits: Predictive models and engineering solutions [Invited] DOMITILLA DEL VECCHIO (Presenter), Massachusetts Institute of Technology MIT — Engineering biology has tremendous potential to impact a number of applications, from energy, to environment, to health. As the sophistication of engineered biological circuits increases, the ability to predict system behavior becomes more limited. In fact, while a system’s component may be well characterized in isolation, the salient properties of this component often change in surprising ways once it interacts with other components in the cell. This context-dependence of biological circuits makes it difficult to perform rational design and often leads to lengthy, combinatorial, design procedures where each component is re-designed \textit{ad hoc} when other parts are added to a system. In this talk, I will review some causes of context-dependence. I will then focus on problems of resource loading and describe a design-oriented mathematical model that accounts for it. I will introduce a general engineering framework, grounded on control theoretic concepts, that can serve as a basis for creating devices that mitigate context-dependence. Example devices will be introduced that mitigate context-dependence due to resource loading in both bacterial and mammalian genetic circuits. These solutions support rational and modular design of sophisticated genetic circuits and can serve for engineering biological circuits that are more reliable and predictable.

1:39PM G36.00005: Universality in Cardiac Dynamics* [Invited] LEON GLASS (Presenter), McGill Univ — Cardiac dynamics displays universal features that stem from similarities in the underlying molecules and structures in the hearts of different species. But the universality can also be considered from the context of nonlinear dynamics. Nonlinear dynamical processes of wave initiation, wave propagation and wave collision prevail over diverse organisms and experimental preparations. Concepts such as period-doubling bifurcations, Cantor sets, and circle maps arise naturally. Application of these concepts provides a physical perspective to the classification of cardiac arrhythmias by cardiologists. Determining the factors that facilitate or impede the persistence of cardiac arrhythmias offer potential directions for improving therapy. I will illustrate these ideas with examples derived from theory, experiment and clinical data with emphasis on paroxysmal rhythms that start and stop suddenly. I will mention several different cardiac arrhythmias including "palpitations", heart block, atrial fibrillation, ventricular tachycardia. The talk may be personally relevant if you (or a close friend or relative) have experienced one of these common arrhythmias.

Session G37 DCMP: Disorder-Driven Transitions in Dirac Materials and Related Systems 605 - Leo Radzihovsky, University of Colorado, Boulder - Tag(s): Invited
11:15AM G37.00001: High-dimensional disorder-driven phenomena in nodal semimetals and systems with long-range hopping [Invited] SERGEY SYZRANOV (Presenter), University of California, Santa Cruz — Systems of non-interacting electrons are believed widely to exhibit only one type of disorder-driven transitions: the Anderson localisation transition. It has been suggested, however, that systems with the power-law quasiparticle dispersion $k^\alpha$ in high dimensions $d>2\alpha$, exemplified by 3D Weyl and Dirac semimetals, may exhibit transitions in a different universality class, as well as unconventional energy-level statistics, Lifshitz tails and ballistic-transport properties. In this talk, I will review existing results on the non-Anderson transitions and other unconventional disorder-driven phenomena in nodal semimetals and related systems (quantum kicked rotors, arrays of ultracold ions, 1D and 2D plasmonic systems, etc.). Also, I will demonstrate that the field theories of disordered nodal semimetals with $\alpha<d$ can be mapped exactly onto those of systems with long-range hopping of quasiparticles, where hopping decays with distance $r$ slower than $1/r^d$ (trapped ultracold ions, spins in solids, nitrogen defects in diamonds, etc.). This duality allows to describe the properties of each of these two classes of systems using the results established for the other class and, in particular, establishes the existence of unconventional disorder-driven transitions in systems with long-range hopping.

11:51AM G37.00002: Disordered Weyl Semimetals: From Lattice Models to the Continuum [Invited] JED PIXLEY (Presenter), Rutgers University, New Brunswick — We will discuss numerical studies of disordered Weyl semimetals focusing on the effects of rare regions at low energy. We will review our work on lattice models of Weyl semimetals which demonstrates the existence of rare region induced non-perturbative eigenstates, an exponentially small but non-zero density of states at the Weyl node, an exponentially large quasiparticle lifetime, and an avoided quantum critical point. We will then present our recent study of a single Weyl cone in the presence of short-range disorder. To numerically handle the continuum we represent the Hamiltonian in a "mixed" way between real and momentum space so that we are able to invoke fast Fourier transforms to take advantage of efficient numerical routines (such as Lanczos and the kernel polynomial method) that rely on sparse matrix-vector multiplications. As a result, we can reach sufficiently large system sizes that are comparable to our lattice model calculations. We will report results on the nature of rare regions and the density of states as a function of the strength of disorder and the ultra violet cut off, as well as compare and contrast single-node and multi-node results. In all of the cases studied, we will demonstrate that the putative semimetal to diffusive transition is rounded into a cross over.

1:03PM G37.00004: Nodal points of Weyl semimetals survive the presence of moderate disorder [Invited] MICHAEL BUCHHOLD (Presenter), Caltech, SEBASTIAN DIEHL, ALEX ALTLAND, University of Cologne — This talk addresses the physics of individual three-dimensional Weyl nodes subject to a moderate concentration of disorder. Previous analysis indicates the presence of a quantum phase transition below which disorder becomes irrelevant and the integrity of sharp nodal points of vanishing spectral density is preserved in this system. This statement appears to be at variance with the inevitable presence of statistically rare fluctuations which cannot be considered as weak and must have strong influence on the system's spectrum, no matter how small the average concentration. We here reconcile the two pictures by demonstrating that rare fluctuation potentials in the Weyl system generate a peculiar type of resonances which carry spectral density in any neighborhood of zero energy, but never at zero. In this way, the vanishing of the DoS for weak disorder survives the inclusion of rare events. We demonstrate this feature by considering three different models of disorder, each emphasizing specific aspects of the problem: a simplistic box potential model, a model with Gaussian distributed disorder, and one with a finite number of s-wave scatterers.

1:39PM G37.00005: Spectrum-wide quantum criticality at the surface of class AIII topological phases: An "energy stack" of integer quantum Hall plateau transitions* [Invited] BJOERN SBIERSKI (Presenter), University of California, Berkeley, JONAS KARCHER, Karlsruhe Institute of Technology, MATTHEW S. FOSTER, Department of Physics and Astronomy and Rice Center for Quantum Materials, Rice University — In the absence of spin-orbit coupling, the conventional dogma of Anderson localization asserts that all states localize in two dimensions, with a glaring exception: the quantum Hall plateau transition (QHPT). In that case, the localization length diverges and interference-induced quantum-critical spatial fluctuations appear at all length scales. Normally QHPT states occur only at isolated energies; accessing them therefore requires fine-tuning of the electron density or magnetic field. In this paper we show that QHPT states can be realized throughout an energy continuum, i.e. as an "energy stack" of critical states wherein each state in the stack exhibits QHPT phenomenology. The stacking occurs without fine-tuning at the surface of a class AIII topological phase, where it is protected by U(1) and (anomalous) chiral or time-reversal symmetries. Spectrum-wide criticality is diagnosed by comparing numerics to universal results for the longitudinal Landauer conductance and wave function multifractality at the QHPT. Results are obtained from an effective 2D surface field theory and from a bulk 3D lattice model. We demonstrate that the stacking of quantum-critical QHPT states is a robust phenomenon that occurs for AIII topological phases with both odd and even winding numbers. The latter conclusion may have important implications for the still poorly-understood logarithmic conformal field theory believed to describe the QHPT.

Tuesday, March 3, 2020 11:15 AM - 2:15 PM
11:15AM G38.00001: Towards Effective, Inclusive Mentorship* [Invited]  THE COMMITTEE ON EFFECTIVE MENTORING IN STEMM, MARIA LUND DAHLBERG (Presenter), The Board on Higher Education and Workforce, The National Academies of Sciences, Engineering, and Medicine — Mentorship has always served an essential role in the process of turning students into science, technology, engineering, mathematics, and medicine (STEMM) professionals. Yet despite the central role that mentorship plays in STEMM culture, mentorship rarely receives the focused attention, evaluation, and recognition of other aspects of the professional development process like teaching and research. There is, however, well-document evidence, theories, and practical implementation strategies that you can use to develop intentional, inclusive, effective mentoring relationships. This talk will review some of the key findings and recommendations from the National Academies consensus study report on The Science of Effective Mentorship in STEMM [1] and the accompanying online guide [2]. It will provide insights into the elements and stages of mentorship and review possible tools to use in your mentoring relationships. It will discuss some principles of institutional culture change and how they relate to supporting a culture of effective, inclusive mentorship.

Sloan Foundation (#G-2017-9885), Burroughs Wellcome Fund (#1017761), and by a grant from the Gulf Research Program of the National Academies of Sciences, Engineering, and Medicine under award number 3-Nov2017-01.
11:51AM G38.00002: Challenges Facing Women in Physics* [Invited] ANNE MARIE PORTER (Presenter), American Institute of Physics — Although the number of women has increased over time, women continue to be underrepresented in the physics field. According to 2018 survey data from the Statistical Research Center at the American Institute of Physics (AIP), women earned 22% of physics bachelor’s degrees, 20% of physics doctoral degrees, and were 19% of faculty members employed in physics departments. Our survey findings also showed that women experience more challenges during their physics career. Based on results from the 2011 PhD Plus 10 survey of mid-career physicists, women earned a significantly lower salary than men, and women more often reported that gender bias and family obligations were barriers during their career. We found that similar challenges were shared by women in physics around the world. The 2018 Global Survey on Gender Gaps in the Sciences surveyed physicists in 159 unique countries, and women were significantly more likely to report negative relationships with their graduate advisors, slower career progression, and experiences with gender discrimination and sexual harassment. These findings can be used to better understand and improve the experiences of women in the physics community.

*The 2018 Global Survey on Gender Gaps in the Sciences was funded by the International Council for Science (ICSU).

12:27PM G38.00003: Mental health challenges for early career physicists [Invited] ANDREA WELSH (Presenter), Georgia Inst of Tech — In the past few years, more studies about poor mental health in academia have been conducted and found that PhD students are almost 3 times as likely to develop mental health problems than then general population. While studies have not been conducted yet on postdoctoral researchers, anecdotal evidence has shown similar concern about mental health on blogs such as Chronically Academic, and others. Topics often linked with poor mental health are work-life balance, job demands, long work hours, supervisor’s leadership, and financial concerns. Many of these stressors are often exacerbated for those with an underrepresented identity with the addition of factors such as stereotype threat, imposter syndrome, or microaggressions. I will discuss the challenges that lead to poor mental health for early career physicists as well as some possible solutions that can be implemented by individuals and the community.

1:03PM G38.00004: Physics abroad, physics at home: a trans perspective on building supportive physics communities [Invited] SAVANNAH GARMON (Presenter), Osaka Prefecture Univ — I will discuss some of my experiences as a trans woman and research physicist who transitioned during her career, which will serve as a backdrop to an exploration of ideas on building stronger and more supportive physics communities, especially for early-career folks. This will include some ideas on better support for postdocs, who may be vulnerable to experiences of isolation and other issues. I will also discuss some outcomes and recommendations from the 2016 report by the APS ad hoc committee on LGBT issues in physics.

1:39PM G38.00005: Monica J Plisch Invited Talk [Invited] —

Tuesday, March 3, 2020 11:15 AM - 2:15 PM
11:15AM G39.00001: Reproducibility, precision and accuracy in $GW$ calculations [Invited]
MICHEL VAN SETTEN (Presenter), IMEC — For many years, computational limits have forced $GW$ calculations to employ approximations without the possibility to systematically evaluate their validity. In such a situation, the search for accuracy and precision can become very challenging, up to the point where one risks sacrificing precision for the sake of accuracy. With increased computational resources, this situation is changing but performing fully converged none approximated $GW$ for solids is still a big challenge. For finite size systems, however, calculations can be more tractable.

In this contribution I summarize the results of the $GW100$ project. The $GW100$ set is a benchmark set of the ionization potentials and electron affinities of 100 molecules computed using the $GW$ method using different independent $GW$ codes and different $GW$ methodologies. The quasi-particle energies of the HOMO and LUMO orbitals are calculated for the $GW100$ set at various levels of approximations. The use of different codes allows for a quantitative comparison of the type of basis set (plane wave or local orbital), handling of unoccupied states, the treatment of core and valence electrons (all electron or pseudopotentials), the treatment of the frequency dependence of the self-energy (full frequency or more approximate plasmon-pole models), and the algorithm for solving the quasi-particle equation.

At present 12 different codes have contributed to the project resulting in over 80 data sets. At $G0W0@PBE$ level very tightly converged results obtained with very different codes, including fully analytic $GW$, answer the question on precision. A comparison of seven different levels of self-consistency in $GW$ to reference values calculated at CCSD(T) level of theory answers the question on accuracy.
11:51AM G39.00002: Solving the Bethe-Salpeter Equation on a Subspace: Approximations and Consequences for Band-Edge and Core-Level Excitons in Quasi Low-dimensional Materials*  DIANA QIU (Presenter), Yale University, FELIPE H. DA JORNADA, Materials Science, Stanford University, STEVEN LOUIE, Physics, University of California, Berkeley and Lawrence Berkeley National Lab — It is known that environment can dramatically renormalize the quasiparticle energy gap and exciton binding energies in quasi low-dimensional materials, but the effect of environmental screening on the energy splitting of the spin-singlet and spin-triplet exciton states is less explored. The renormalization of the exciton binding energy arises from additional environmental screening of the attractive direct Coulomb term in the kernel of the Bethe-Salpeter equation (BSE). The repulsive exchange interaction responsible for the singlet-triplet slitting is in principle unscreened, though it has been argued that in practical calculations using a subspace of the full Hilbert space the exchange interaction should be modified and effectively screened by states outside of the chosen subspace, the “S” approximation. We explore the accuracy of the S approximation for different systems, including molecules, heterostructures and core level excitations. We show, additionally, that the S approximation is actually exact in the limit of small exciton binding energies provided that a screening consistent with the Tamm-Dancoff approximation is employed.

*This work was supported by C2SEPEM, which is funded by the U.S. DOE, Office of Science, Basic Energy Sciences, under Contract No. DE-AC02-05CH11231.

12:03PM G39.00003: Pyrene-Stabilized Acenes as Intermolecular Singlet Fission Candidates: Importance of Exciton Wave-Function Convergence  XINGYU ALFRED LIU (Presenter), RITHWIK TOM, XIAOPENG WANG, Carnegie Mellon University, BOHDAN SCHATSCHNEIDER, Cal-Poly Pomona, NOA MAROM, Carnegie Mellon University — Singlet fission (SF) is the conversion of a singlet exciton into two triplet excitons. SF could increase the efficiency of organic solar cells by harvesting two carriers from one photon. Polyacene crystals, such as tetracene and pentacene, have shown outstanding SF performance. However, their instability prevents them from being utilized in SF-based photovoltaic devices. In search of practical SF chromophores, we use many-body perturbation theory with the GW approximation and Bethe-Salpeter equation to study the excitonic properties of pyrene-stabilized acenes. We propose a criterion to determine the convergence of exciton wave-functions with respect to the fine k-point grid used in the BerkeleyGW code. An open-source Python code is presented to perform exciton wave-function convergence checks and streamline the double-Bader analysis of exciton character. We find that the singlet excitons in pyrene-stabilized acenes have a higher degree of charge transfer character than in the corresponding acenes. The pyrene-fused tetracene and pentacene derivatives exhibit comparable excitation energies to their corresponding acenes, making them potential SF candidates. The pyrene-stabilized anthracene derivative is considered as a possible candidate for triplet-triplet annihilation (TTA).
12:15PM G39.00004: An energetics perspective on why there are so few triplet-triplet annihilation emitters  XIAOPENG WANG, RITHWIK TOM, XINGYU ALFRED LIU, NOA MAROM (Presenter), Carnegie Mellon University — The efficiency of organic solar cells may be increased by utilizing photons with energies below the band gap of the absorber. This may be enabled by upconversion of low energy photons into high energy photons via triplet-triplet annihilation (TTA). The quantum yield of TTA is often low due to competing processes. The singlet pathway where a high-energy photon is emitted has a 1/9 probability according to the Clebsch-Gordon rules. The quintet pathway is typically too high in energy to be accessible, leaving the triplet pathway as the main competing process. Using many-body perturbation theory in the GW approximation and the Bethe–Salpeter equation, we calculate the energy release in both the singlet and triplet pathways in 61 chromophores of different chemical families. We find that in most cases the triplet pathway is open and has a larger energy release than the singlet pathway. Thus, the energetics perspective explains why there are so few TTA emitters and their low quantum yields.

12:27PM G39.00005: Analysis of Excitons in Stacked Perylene Diimide Derivatives*  KASIDET JING TRERAYAPIWAT (Presenter), Department of Chemistry, Boston University, ALIYA MUKAZHANOVA, Division of Materials Science and Engineering, Boston University, SAHAR SHARIFZADEH, Department of Electrical and Computer Engineering, Boston University — π-stacked organic molecules are tunable light-absorbing materials that are promising for many optoelectronic applications; thus, it is necessary to understand how both inter- and intra-molecular interactions influence optical excitations. We use first-principles time-dependent density functional theory (TDDFT) to study the nature of these interactions in functionalized perylene diimide oligomers stacked on a DNA-like backbone. Taking a Franck-Condon Herzburg-Teller approach to vibronic coupling, and sampling of ground state vibrations via molecular dynamics, we obtain an ensemble of excited-states that may occur. By analyzing ~100 dimer and trimer structures, we elucidate the parameters that correlate with the nature of the excited-state. Charge transfer (CT) character analysis shows that the degree of CT-like character in a bright state correlates with the strength of electronic transition and with its inter-molecular vibrations. Furthermore, we determine that displacement and rotation between monomers leads to reordering of direct excitations. Such a finding is important for technologies such as singlet fission photovoltaics where the CT excitation character is directly related to performance.

First-principles $G_0W_0$ calculations for ferrocene, anthracene and porphyrin* MASOUD MANSOURI (Presenter), Centro de Física de Materiales-MPC (CSIC-UPV/EHU), PETER KOVAL, Donostia International Physics Center (DIPC), DANIEL SANCHEZ-PORTAL, Centro de Física de Materiales-MPC (CSIC-UPV/EHU) — Hedin's GW approximation is well-known as a powerful method in the material science community because of its high quality and relatively low computational cost. In this study, we evaluate the performance of the $G_0W_0$ approximation for the charged quasi-particle excitation energies of three gas-phase molecules of interest for organic electronics, including ferrocene, porphyrin and anthracene. Moreover, we assess the undesired starting-point dependence in this method by benchmarking the ionization energies obtained from $G_0W_0$ on top of the spin-resolved Hartree-Fock and Kohn-Sham methods. The merit of dynamic effective GW self-energy leads to significant improvement of ionization energies compared to mean-field calculations and deviations less than 0.4 eV as compared to experiment. The calculations are carried out by the use of numerical atomic orbitals and contour deformation technique along with an iterative procedure to deal with the energy dependency of GW self-energy and full matrix elements of the dynamically screened Coulomb interaction.

Exciton temperature dependence dictated by localization in organic semiconductors* ANTONIOS ALVERTIS (Presenter), RICHARD H. FRIEND, AKSHAY RAO, Univ of Cambridge, ALEX W. CHIN, Sorbonne University, BARTOMEU MONSERRAT, Univ of Cambridge — The response of organic semiconductors in optoelectronic devices is dominated by room temperature excitons. However, exciton calculations of organic crystals at finite temperature can be challenging, due to the need to combine the effects of exciton-phonon coupling and thermal expansion. Here we overcome this challenge by employing a combination of Green's function methods for the electronic structure, and non-perturbative finite difference methods for the interaction with the lattice. We apply our methodology to the acene series of molecular crystals and find that different localization ranges of excitons lead to different responses to exciton-phonon coupling and thermal expansion. As a result, the energies of singlet and triplet excitons have different temperature dependencies, as do the singlet energies between the different materials. We expect that the combination of exciton-phonon coupling and thermal expansion, together with their interplay with the exciton localization range, provides a general mechanism for understanding the temperature dependence of exciton energies in molecular crystals.

**1:03PM G39.00008: Probing energy transfer design principles in photosynthetic light harvesting systems with predictive electronic structure calculations**  
CAROLINE MCKEON (Presenter), SAMIA M HAMED, University of California, Berkeley, CHENCHEN SONG, Lawrence Berkeley National Laboratory, JEFFREY B NEATON, University of California, Berkeley — A thorough theoretical understanding of photosynthetic light-harvesting systems is critical to our ability to mimic their unparalleled energy transduction efficiency in synthetic contexts. Here, we present a workflow for calculating optical absorption spectra of chromophore monomers and dimers within the Franck-Condon approximation, using classical molecular dynamics simulations, and time-dependent density functional theory. We apply our approach to Sulforhodamine B (SRB) and AlexaFluor488 chromophore monomers and dimers and compare our results with complementary experimental absorption spectra. We discuss how conformation, the presence of counter-ions, solvation models, and choice of functional influence the predicted absorption spectra. We discuss progress towards identifying key factors in the high quantum efficiencies found exclusively in natural photosynthetic systems. This work is supported by the Department of Energy.

*This work is supported by the Department of Energy and computational resources are provided by the Molecular Graphics Facility at University of California, Berkeley.

**1:15PM G39.00009: Exciton coherence times and diffusion constants in molecular crystals from exciton-phonon coupling with an ab initio GW-BSE approach**  
JONAH HABER (Presenter), Physics, University of California, Berkeley, FELIPE DA JORNADA, Materials Science and Engineering, Stanford University, SIVAN REFAELY-ABRAMSON, Department of Materials and Interfaces, Weizmann Institute of Science, GABRIEL ANTONIUS, Département de Chimie, Biochimie et Physique, Université du Québec à Trois-Rivières, Trois-Rivières, STEVEN LOUIE, JEFFREY B NEATON, Physics, University of California, Berkeley — Predictive theories of exciton dynamics are of growing importance as increasingly complex materials, with strong electron-hole interactions, are used in device physics applications. For instance, in organic photovoltaics, an important part of energy conversion processes involves the diffusion of a photo-excited exciton to donor-acceptor interfaces where charge separation can occur. To quantitatively understand exciton dynamics, a microscopic theory of exciton-phonon interactions is required. Here, we describe an ab initio framework for computing exciton-phonon matrix elements, using density functional perturbation theory in conjunction with many-body perturbation theory within the GW plus Bethe-Salpeter equation (BSE) approach. We apply this formalism to crystalline tetracene, a prototypical organic semiconductor with strong electron-hole interactions. We compare and contrast how low-lying spin singlet and triplet excitons couple to the phonon field. We perturbatively compute phonon-limited exciton coherence times throughout the Brillouin zone and report exciton diffusion constants, evaluated using the relaxation time approximation. In all cases, we compare with experimental measurements, where available.

**1:27PM G39.00010: Effects of dynamical lattice screening on excitonic and optical properties of polar compounds**

JOSHUA LEVEILLEE (Presenter), XIAO ZHANG, ANDRE SCHLEIFE, University of Illinois at Urbana-Champaign — The Bethe-Salpeter equation (BSE) framework is very common for predicting optical and excitonic properties in materials. Typically, only high-frequency electronic dielectric screening is considered in the screened electron-hole Coulomb interaction. In materials hosting polar phonon modes that induce macroscopic electric fields, there is an additional dynamical lattice screening effect. To describe this contribution, we use the Shindo approximation and the Fröhlich model to predict exciton binding energies in NaCl, MgO, AlN, and GaN. Dynamical lattice screening exerts a small influence on the excitonic properties of the high band gap materials NaCl and MgO. In AlN, the predicted exciton binding energy reduces from 145 to 112 meV. In GaN, dynamical lattice screening drastically reduces the exciton binding energy from 52 to 30 meV, in good agreement with experiments. The optical spectra for all compounds are predicted to be in good agreement with experimental spectra under the inclusion of effective dynamical lattice screening, and we find that it is a critical contributor to the screened electron-hole interaction in polar materials with low exciton binding energies and high longitudinal optical phonon frequencies.

TOMMASO FRANCESE (Presenter), University of Chicago, FRANCOIS GYGI, University of California Davis, GIULIA GALLI, University of Chicago — Thermally activated delayed fluorescence compounds (TADFs) are a class of purely organic light emitting diodes\[1\] based on reverse intersystem crossing processes. Despite the successful synthesis of blue/green TADF compounds, the search for efficient orange-red fluorescent TADFs remains an open problem. NAI-DMAC\[2\] \([C_{37}H_{32}N_2O_2]\) is one of the few orange-red light emitters with an external quantum efficiency of ~ 30%. Here we present a first principle study of NAI-DMAC both in the dilute and solid state limit. We carried out First-Principles Molecular Dynamics simulations with the Qbox code (http://qboxcode.org) at different temperatures and computed ground to excited state transitions by employing range-separated hybrid functionals\[3\], as well as the SCAN functional\[4\]. We present results for the energy difference between singlet and triplet excited states (\(\Delta E_{ST}\)), and we discuss how \(\Delta E_{ST}\) is related to structural differences in the ground and excited states, in particular to the dihedral angle between the donor and acceptor moieties.

1:51PM G39.00012: Predictive and Tractable GW Approach for Energy Level Alignment at Organic-Inorganic Interfaces with Significant Charge Transfer*  
NICHOLAS LIN QUAN CHENG (Presenter), FENGYUAN XUAN, SU YING QUEK, Natl Univ of Singapore — The energy level alignment (ELA) at organic-inorganic interfaces is critical for determining charge injection barriers in organic and molecular electronic devices. Many-body perturbation theory in the GW approximation enables the quantitative prediction of ELA in many systems, but can be computationally challenging for large interfaces. We have recently developed an approach [1] to perform GW calculations on large interface systems, which involves the expansion of the polarizability (chi) matrix from a unit cell to the supercell, the addition of chi from the two subsystems, and the use of wavefunctions from the Full interface to compute the self-energies. This XAF-GW method has been shown to work even in the presence of interface hybridization to form bonding and antibonding orbitals. Here, we show that the XAF-GW method fails in some cases with significant interface charge transfer. We modify the XAF-GW approach to specifically account for charge transfer effects, and obtain good agreement between the modified XAF-GW method and a regular full GW calculation for F4TCNQ on bilayer graphene. We further discuss the application of our new approach to other experimentally relevant systems.

2:03PM G39.00013: Electronic structure of semiconductor nanoparticles from stochastic evaluation of imaginary-time path integral: nonrelativistic U(1) lattice gauge theory in the Kohn-Sham basis  
ANDREI KRYJEVSKI (Presenter), North Dakota State Univ — In the Kohn-Sham orbital basis imaginary-time path integral for electrons in a semiconductor nanoparticle has a mild fermion sign problem and is, therefore, amenable to evaluation by the standard stochastic methods. Utilizing output from the density functional theory simulations with Perdew, Burke and Ernzerhof exchange-correlation functional we compute imaginary-time electron propagators in several silicon hydrogen-passivated nanocrystals, such as Si_{35}H_{36}, Si_{87}H_{76} and Si_{147}H_{100}, and extract energies of low-lying electron and hole levels. Our quasiparticle gap predictions agree with the results of recent G\textsubscript{0}W\textsubscript{0} calculations from M. Govoni, G. Galli, “Large Scale GW Calculations”, J. Chem. Theory Comp., 11 (2015).

Session G40 DCOMP DMP: Matter in Extreme Environments I: Advanced Experiments 705 - Xiaoyu Wang - Tag(s): Focus
Despite being the subject of numerous shock compression studies, the behavior of silicon under dynamic loading is vigorously debated [1-4]. The few studies that combine shock compression and X-ray diffraction have exclusively focused on "normal" X-ray geometry whereby X-rays are collected along the shock propagation direction, consequently sampling numerous strain states at once, and hence greatly complicating both phase identification and studies of phase transition kinetics.[5] Here, we present a novel setup to perform in situ X-ray diffraction studies perpendicular to the shock propagation direction at the Matter in Extreme Conditions end station at Linac Coherent Light Source, SLAC. Combining the extremely bright, micro-focused X-ray beam available at the LCLS with a nanosecond laser driver, we unambiguously characterize of the complex multi-wave shock response in silicon for the first time. We further combine this platform with simultaneous imaging with diffraction from shock compressed germanium.

11:51AM G40.00002: Laser shock induced insulator-metal transition in quasi-one dimensional single-component radical

YONG HU (Presenter), SHENQIANG REN, State Univ of NY - Buffalo — Laser shock is a relatively new surface treatment for high pressure study[1]. The shock waves can create over one hundred GPa transient shock pressure[2]. Here we found the laser shock induced revisable insulator-metal transition in single-component radical, K-TCNQ[3], where the effect of antiferromagnetic spin ordering causes insulating behavior. The manipulation of spin exchange interaction with external laser shock wave, electric field and magnetic field is accompanied by insulator to metal transition, gigantic magnetoelectric and magneto capacitance effects. One dimensional systems therefore provide a new area to search for conducting magnetoelectric media.

12:03PM G40.00003: Overview of High Pressure Collaborative Access Team (HPCAT) facility at the Advanced Photon Source at Argonne National Laboratory

NENAD VELISAVLJEVIC (Presenter), Lawrence Livermore Natl Lab, MADDURY SOMAYAZULU, HPCAT, APS, X-ray Science Division Argonne National Laboratory — HPCAT is a dedicated facility for high pressure research and is located within the Advanced Photon Source. Goal of HPCAT is to develop and implement synchrotron-based x-ray techniques that are coupled with diamond anvil cell, portable large volume press, and other platforms for studying materials at extreme pressure-temperature conditions.

Comprised of four simultaneously operational beamlines, HPCAT is the largest dedicated high-pressure synchrotron-based facility in the world and provides broad range of cutting-edge x-ray techniques, as well as complementary high-pressure support equipment. Over the years numerous high-pressure x-ray diffraction, spectroscopy, and imaging techniques have been developed and established for high pressure research through a robust national laboratory and university partnership, and broad general user operation.

Currently, HPCAT has two insertion device beamlines, one for diffraction and the other for spectroscopy, and two bending magnet beamlines, one for general purpose and the other for white-beam application. Our presentation will provide overview of HPCAT and recent experimental techniques being developed.

*HPCAT operations are supported by DOE-NNSA's Office of Experimental Sciences.
12:15PM G40.00004: Crystal Structure and Reflectivity of Laser Ramp-Compressed Sodium*

[Invited] DANAE POLSIN (Presenter), XUCHEN GONG, LINDA CRANDALL, MARGARET F HUFF, THOMAS BOEHLY, GILBERT W COLLINS, JAMES R RYGG, University of Rochester, JON HENRY EGGERT, AMY JENEI, MARIUS MILLOT, Lawrence Livermore National Laboratory, MALCOLM I McMAHON, University of Edinburgh — Extreme compression can alter the free-electron behavior of “simple” metals such as sodium. At pressures exceeding 200 GPa, Na was observed to become transparent to visible light under static compression. First-principles calculations suggest this is caused by a transformation to an electride phase where electrons are localized in interstitial positions. Laser-driven ramp compression is used to compress Na into an unexplored pressure regime to investigate the crystalline structure, reflectivity, and melting behavior. X-ray diffraction is used to constrain the crystalline structure and detect melting. Optical reflectivity measurements at 532 nm are used to detect a transition to the observed insulating electride phase. We show the highest-pressure solid x-ray diffraction and reflectivity data on Na to date. The results indicate the Na phase diagram is more complicated than predicted by zero-temperature DFT.

12:51PM G40.00005: Neutron Scattering Research on Quantum Materials under Pressure*

ANTONIO DOS SANTOS (Presenter), Oak Ridge National Lab — Quantum Materials are characterized by an extreme sensitivity to weak external perturbations (H, E, P). Among these, pressure is unique in that, even in a moderate range, it induces structural changes energetically equivalent to thousands of K. In addition, samples subjected to pressure do not suffer from chemical segregation or disorder, characteristic of chemical manipulation. In this context, neutron scattering, with its ability to inspect simultaneously the lattice and spin degrees of freedom, while not depositing any energy, is uniquely suitable for the study of quantum systems. Instruments at modern neutron sources, such as the spallation neutron source, are now fitted with custom made pressure devices, that extend the realm of the possible in neutron scattering of the quantum world. Indeed, the range of pressure, temperature and field available, allow faster measurements on smaller samples. Here we will present the current suite of instrumentation available to research of quantum materials at the SNS, including new developments in instrumentation and pressure devices. These advances will be illustrated with science examples that benefited from these new capabilities.

**1:03PM G40.00006: Magnetic Structure of the High-Pressure Phases of Holmium**

CHRISTOPHER PERREAULT (Presenter), YOGESH VOHRA, Department of Physics, Univ of Alabama - Birmingham, ANTONIO MOREIRA DOS SANTOS, JAMIE MOLAISON, Neutron Scattering Division, Oak Ridge National Laboratory — The magnetic phases in rare earth metals are well established under ambient pressure conditions, however, little is known about the magnetic ordering in their corresponding high pressure crystalline modifications. Holmium (Ho) was studied in a large-volume diamond anvil cell at the Spallation Neutron Source to 20 GPa and 10 K. The ambient pressure hexagonal close packed phase (hcp) of holmium shows two magnetic transitions below 10 GPa one to Antiferromagnetic (AFM) incommensurate phase and another to a Ferromagnetic (FM) phase. At pressures above 10 GPa, Ho transforms to the alpha-Samarium (α-Sm) phase which shows only one transition marked by appearance of a magnetic peak at 3 Å below 20 K that is more intense than the nuclear peaks. This magnetic order remains even when pressure is increased past 19 GPa where the sample again transforms, this time to the double hexagonal close packed (dhcp) phase. The magnetic ordering temperature increases with pressure from below 20 K at 15 GPa to around 25 K at 20 GPa. The magnetic phase diagram of Ho is presented to 20 GPa and 10 K.

**1:15PM G40.00007: Lattice Dynamics of Highly Porous Materials**  
MATTHEW RYDER (Presenter), Oak Ridge National Lab — Highly porous materials such as MOFs, COFs and HOFs have been shown to have promising electronic and dielectric properties. However, high levels of porosity often couple with low structural stability. Therefore, the collective lattice dynamics reveal a diversity of valuable information relating to the structural flexibility and the mechanistic origins of anomalous mechanical phenomena. Spectroscopic techniques such as inelastic neutron scattering (INS), in conjunction with DFT, are used to study the phonon mode dynamics, including those related to gate opening and breathing, trampoline-like mechanisms and molecular rotors reminiscent of negative thermal expansion (NTE), and buckling of 2D layers. The work has also revealed the effect of external stimuli (pressure and temperature) and shown stimuli-induced phase transitions and amorphization.

8. CrystEngComm, 18, 4303 (2016)  
Mechanochemical activation by high-energy milling has become a widely used method for solid state synthesis, and alternative to high-temperature processes. It has been successfully used for synthesis of crystalline and amorphous alloys, intermetallic compounds, metastable phases, nanomaterials and metal-ceramic composites. Mechanochemical synthesis utilizes high-energy impact phenomena to initiate chemical reactions or structural phase transitions. The peak impact pressures which the individual sample particles experience vary depending on the type of mill, milling speed, as well as size, shape and density of the attritor components, but can reach 20 GPa, while the temperature typically remains below 100°C. Remarkably, this is achieved with significant sample quantities (grams), over a short period of time, and very inexpensively. Whereas mechanisms and kinetics of solid-state reactions induced by temperature or static pressure are fairly well understood, transformations of materials under continuous impact in a milling assembly remain largely unexplored and are based almost exclusively on ex situ studies. During the mechanical activation particles undergo heavy deformation and experience significant strains. This results in formation of a variety of crystal defects such as dislocations, vacancies, stacking faults and increased number of particle boundaries, making the milled material energetically less stable. An on-going project at the PX² synchrotron beamline will adapt the in situ real-time X-ray diffraction monitoring of structural and chemical changes during the milling process. This presentation will also introduce a new project to develop more economical mechanochemical paths towards synthesis of the cubic phase of boron nitride.

*Funding from ONR MI/HBC program and COMPRES under NSF Cooperative Agreement EAR-1661511 is gratefully acknowledged.

Session G41 GMAG: Magnetic Characterization and Imaging 707 - Cosmin Radu, Lake Shore Cryotronics (United States) - Tag(s): Focus
11:15AM G41.00001: Optical characterization of in-plain spin texture in 10-nm-scale Neel-type magnetic domain wall

DONGHA KIM (Presenter), KAB-JIN KIM, MIN-KYO SEO, KAIST — We present that dark-field longitudinal magneto-optical Kerr effect (MOKE) microscopy can visualize the in-plain spin texture of the subwavelength-scale Neel-type magnetic domain wall. Conventional MOKE microscopy has never resolved the spin texture at the nanoscale due to not only the optical diffraction limit but also extremely small magneto-optic (MO) susceptibility. The dark-field illumination isolates the MOKE signal of the domain wall from those of the magnetic domains effectively with a high signal-to-background ratio. Also, we employed a perfect optical absorption multilayer to vanish the non-MO signals dramatically and boost the measurement efficiency. We examined the Neel-type magnetic domain wall of the Pt/Co/Pt/Ta film and measured its MO scattering width to be ~9.14 pm, experimentally. The intensity of the longitudinal MOKE signal from the domain wall depends on the orientation of in-plane magnetization relative to the azimuthal angle of incidence. Angle-dependent, precise measurement of the longitudinal MOKE scattering enables us to identify spatial magnetization distribution along the 10-nm-scale magnetic domain wall. We expect our work will offer a new possibility in research on complex in-plane spin textures such as vertical Bloch lines and skyrmions.

11:27AM G41.00002: Microsphere-assisted super-resolution magneto-optic imaging

MICHAEL VOGEL (Presenter), Argonne Natl Lab, ARTHUR HENDRIKS, Department of Applied Physics, Eindhoven University of Technology, SUZANNE TE VELTHUIS, AXEL HOFFMANN, Argonne Natl Lab — The diffraction limit [1] is a fundamental barrier in optical imaging. It can be surpassed by the photonic nanojet phenomenon, generated by a lens-like dielectric micro-object [2]. Microspheres have been demonstrated as a powerful platform to challenge the diffraction limit by creating a virtual image with enhanced resolution and magnification [3,4]. Here we report on wide-field MOKE (Magneto-Optical Kerr effect) measurements harnessing this resolution enhancement. In-plane and perpendicular magnetized domains, probed with the longitudinal and polar Kerr effects, respectively, are imaged at increase spatial resolution. Our findings may serve as a way to combine the advantages of fast time resolution and versatile sample environment of optical measurements with smaller length scales.

*Work at Argonne was supported by the US-DOE, Office of Science, MSED. Use of the Center for Nanoscale Materials was supported by the US-DOE, Office of Science, BES, under contract no. DE-AC02-06CH11357.
Magnetic Resonance Imaging* YOUNG JIN KIM (Presenter), IGOR M SAVUKOV, Los Alamos Natl Lab — Magnetic resonance imaging (MRI) in the ultra-low field (ULF) regime is a promising method for anatomical imaging with multiple advantages over conventional several-Tesla MRI. The leading high-sensitivity multichannel ULF MRI was realized only with multichannel superconducting quantum interference devices (SQUIDs); however, the need for cryogenic infrastructure is a serious drawback. We aim to develop an alternative, more practical ULF MRI based on a high-sensitivity multichannel atomic magnetometers (AMs) and multiple flux transformers (FTs). AMs are currently the most sensitive non-cryogenic magnetic-field sensors. Our approach represents the first ULF MRI implementation using the novel technique, which has many innovative features such as acceleration of MRI, a large array of sensors based on a single large atomic vapor cell, reducing the cost of sensors ~10 times, and flexible design based on FTs. In this talk, we will describe the basic principle and the design of our ULF MRI system.

*We acknowledge the support of the U.S. Department of Energy through the LANL Laboratory Directed Research Development program for this work
Ionically-controlled phase separation in cobaltite heterostructures

[Invited] GEOFFERY RIPPY, LACEY L TRINH, ALEXANDER MICHAEL KANE, ALEKSEY IONIN, MICAHEL LEE, University of California, Davis, RAJESH V CHOPDEKAR, Lawrence Berkeley National Laboratory, JOYCE CHRISTIANSEN-SALAMEH, University of California, Davis, DUSTIN GILBERT, University of Tennessee, ALEXANDER GRUTTER, NIST Center for Neutron Research, PEYTON MURRAY, University of California, Davis, MARTIN HOLT, ZHONGHOU CAI, Argonne National Laboratory, KAI LIU, Georgetown University, YAYOI TAKAMURA, ROOPALI KUKREJA (Presenter), University of California, Davis — Complex oxide heterostructures provide access to emergent functional and structural phases which are not present in the bulk constituent materials. Controlling ionic distribution and stoichiometry in complex oxide heterostructures has been utilized to significantly alter and tune the electronic, magnetic, and structural properties. Recently, deposition of a strong oxygen getter on top of an oxide thin film has emerged as a novel way to tailor oxygen stoichiometry and nanoscale functional properties. However, the role played by nanoscale morphology, i.e. phase separation and defects in these oxide thin films and heterostructures remains largely unknown. In this talk, I will focus on Gd/\text{La}_{0.67}\text{Sr}_{0.33}\text{CoO}_3 (LSCO) heterostructures due to the high oxygen ion conductivity, as well as the coupled magnetic and electronic properties of LSCO, which are strongly dependent on the oxygen stoichiometry. This combination of properties enable the ionic control of the functional properties of LSCO thin films through the presence of oxygen getter layers such as Gd. We utilize x-ray nanodiffraction to directly image the nanoscale morphology of LSCO thin films as they are progressively transformed from the equilibrium perovskite phase to the metastable brownmillerite (BM) phase with increasing Gd thickness. Our studies show the coexistence of perovskite and BM phases with a critical oxygen vacancy concentration threshold which leads to the formation of extended BM filaments. Strain maps reveal that the perovskite phase changes from compressive to tensile strain on opposite sides of a BM filament. Our studies provide an unprecedented nanoscale survey of the phase separation in the cobaltites and shed light on the formation of the metastable BM phase.

"Magnetic Etch-a-Sketch" using the 1st-order phase transition in FeRh*

ISAIAH GRAY (Presenter), School of Applied and Engineering Physics, Cornell University, ANTONIO B MEI, Department of Materials Science and Engineering, Cornell University, YONGJIAN TANG, Department of Physics, Cornell University, JÜRGEN SCHUBERT, Peter Grünberg Institute (PGI-9) and Jara-Fundamentals of Future Information Technology, Forschungszentrum Jülich, DON WERDER, Cornell Center for Materials Research, Cornell University, JASON M BARTELL, Department of Materials Science and Engineering, Massachusetts Institute of Technology, DANIEL RALPH, Department of Physics, Cornell University, GREGORY FUCHS, School of Applied and Engineering Physics, Cornell University, DARRELL SCHLOM, Department of Materials Science and Engineering, Cornell University — We demonstrate a novel approach for room-temperature rewritable magnetic patterning using the 1st-order phase transition from antiferromagnet (AF) to ferromagnet (FM) in FeRh. We employ epitaxial Fe$_{0.52}$Rh$_{0.48}$ films designed such that both phases are metastable at room temperature. Starting with the film in a uniform AF state, we write arbitrary patterns of FM phase using a focused pulsed laser with ~650 nm resolution. We image the FM patterns with anomalous Nernst microscopy and show that they are stable under magnetic field – at least up to 3 kOe – as well as elevated temperature up to ~315 K. The FM patterns can be written using a single picosecond laser pulse per pixel and can be fully erased by cooling the film below room temperature.

**12:39PM G41.00006: Novel sample preparation and detection method for magnetic resonance force imaging of electron spins**

MICHAEL BOUCHER (Presenter), JOHN A MAROHN, Cornell University — Magnetic resonance force microscopy (MRFM) is a technique that opens up the possibility of extremely sensitive detection and imaging of electron spins, with sensitivity capable of detecting a single radical. In our experiment, we detect a change in magnetization of nitroxide radical probes as a shift in the frequency of a magnet-tipped cantilever. We discuss recent developments that have allowed us to overcome difficulties with this measurement. One difficulty is frequency noise from sample dielectric fluctuations interacting with charges on the cantilever tip. We have found that we can reduce this noise by applying a 10 nm metal coating over the sample. However, deposition of this metallic coating produces a “dead layer” in which nitroxide labels are no longer active. We show a new sample preparation technique which applies this coating without exposing sample radicals during metal deposition. Another difficulty is that the motion of the cantilever magnet causes a change in the resonance frequency of spins during the microwave pulses, which leads to image blurring and reduction in sensitivity. We show ways to “pause” cantilever motion during microwave application to prevent blurring and improve sensitivity.

*We acknowledge funding from the Army Research Office Grant W911NF1710247*

**12:51PM G41.00007: NV$^-$ center magnetometry using Bayesian statistics**

SERGEY DUSHENKO (Presenter), KAPILDEB AMBAL, University of Maryland, College Park/National Institute of Standards and Technology, ROBERT MCMICHAEL, National Institute of Standards and Technology — In magnetometry using NV$^-$ centers, we demonstrate order-of-magnitude speed up with Bayesian experimental design as compared to conventional frequency-swept measurements. The NV$^-$ center is a quantum defect with spin 1 and coherence time up to several milliseconds at room temperature. Zeeman splitting of NV$^-$ energy levels allows detection of the magnetic field via photoluminescence. It is an excellent platform for magnetometry with potential spatial resolution down to few nanometers and demonstrated sensitivity down to nT/Hz$^{1/2}$.

We compare conventional magnetic field measurement of fluorescence under pre-determined sweeps of microwave frequency with the measurement using a Bayesian statistics methodology. In the Bayesian experimental design, the frequency of each measurement is determined in real-time from utility predictions based on the accumulated experimental data. We report order of magnitude increase in the precision of magnetic field and hyperfine splitting determination for the same measurement time in the Bayesian scheme, compared with the conventional scheme.

1:03PM G41.00008: Imaging nanoscale magnetization using scanning-probe magneto-thermal microscopy*  
CHI ZHANG (Presenter), JASON M BARTELL, JONATHAN KARSCH, ISAIAH GRAY, GREGORY FUCHS, Cornell University — High resolution, time-resolved magnetic microscopy is crucial for understanding novel magnetic phenomenon such as skyrmions, spinwaves, and domain walls. Currently, achieving 10-100 nanometer spatial resolution with 10-100 picosecond temporal resolution is beyond the reach of table-top techniques. To break free of the far-field diffraction limit, we have developed a near-field magnetic microscope based on magneto-thermo interactions: the time-resolved anomalous Nernst effect and the time-resolved longitudinal spin Seebeck effect. Our technique involves scanning a sharp gold tip within a near-field optical excitation. The resulting tip-sample interaction creates a nanoscale thermal gradient for magneto-thermal microscopy, and its extension to imaging an applied current density. We study the characteristics of near-field thermal excitation with a picosecond laser and demonstrate magnetic imaging of a multi-domain state. We present sub-100 nm spatial resolution from imaging current density around a nano-constriction. Our results suggest a new approach to nanoscale spatiotemporal magnetic microscopy in an accessible, table-top form to aid in the development of high-speed magnetic devices.

1:15PM G41.00009: Multi-axis cavity optomechanical torque characterization of magnetic microstructures and the contribution of the Einstein-de Haas effect  
JOSEPH LOSBY (Presenter), GHAZAL HAJISALEM, Univ of Calgary, KAYTE MORI, Physics, University of Alberta, GUSTAVO DE OLIVEIRA LUIZ, Univ of Calgary, VINCENT SAUER, MARK R FREEMAN, Physics, University of Alberta, PAUL BARCLAY, Univ of Calgary — Significant new functionality is reported for torsion mechanical tools aimed at full magnetic characterizations of both spin statics and dynamics in micro- and nanostructures. Specifically, multiple torque directions utilizing higher order mechanical modes are monitored, as is essential for study of anisotropic three-dimensional structures. The approach is demonstrated through application to shape and microstructural disorder-induced magnetic anisotropies in lithographically patterned permalloy, and will have utility for the determination of important magnetic thin-film and multilayer properties including interface anisotropy and exchange bias.

With the extension of torque magnetometry measurements into radio frequencies, the contribution of the Einstein-de Haas (EdH) effect can become comparable to the conventional magnetic cross-product signal. Through sensitive optomechanical detection of higher order mechanical modes, the torques owing to the EdH effect are elucidated, and offer a new method for exploring high frequency magnetic susceptibility in anisotropic structures.
Nano-engineered magnetic materials are of great interest for tuning magnetic interactions and because of their potential applications for next-generation spintronic devices. Nanoscale 3D magnetization textures such as inverse nickel metallaticates can be fabricated by infiltrating close-packed silica nanospheres with nickel. Such structures can support many distinct magnetic phases and topologies, leading to a new class of nanostructured magnetic metamaterials. Despite recent success in theoretical predicting and fabricating these materials, 3D characterization of their structure and properties remains very challenging due to the lack of suitable microscopy tools. We developed a new 3D nanoscale magnetic imaging capability that combines x-ray magnetic circular dichroism, ptychographic imaging, and vector tomography. Using this new magnetic vector ptycho-tomography method on a synchrotron beamline, we imaged a nickel magnetic metallatice sample to unveil the underlying structure and spin texture.

*We gratefully acknowledge support for this work by STROBE: A National Science Foundation Science & Technology Center, under Grant No. DMR 1548924.
1:39PM G41.00011: Scaling of domain cascades in stripe and skyrmion phases*  ARNAB SINGH, Saha Institute of Nuclear Physics, JAMES LEE (Presenter), Sonoma State University, KARINA E. AVILA, University of Illinois, Urbana-Champaign, YUAN CHEN, Lawrence Berkeley National Laboratory, SERGIO MONTOYA, ERIC FULLERTON, University of California, San Diego, PETER FISCHER, Lawrence Berkeley National Laboratory, KARIN ANDREA DAHMEN, University of Illinois, Urbana-Champaign, STEPHEN DOUGLAS KEVAN, Lawrence Berkeley National Laboratory, MILAN K. SANYAL, Saha Institute of Nuclear Physics, SUJOY ROY, Lawrence Berkeley National Laboratory — The origin of deterministic macroscopic properties often lies in microscopic stochastic motion. Magnetic fluctuations that manifest as domain avalanches and chaotic magnetization jumps exemplify such stochastic motion and have been studied in great detail. Here we report Fourier space studies of avalanches in a system exhibiting competing magnetic stripe and skyrmion phase using a soft X-ray speckle metrology technique. We demonstrate the existence of phase boundaries and underlying critical points in the stripe and skyrmion phases. We found that distinct scaling and universality classes are associated with these domain topologies. The magnitude and frequency of abrupt magnetic domain jumps observed in the stripe phase are dramatically reduced in the skyrmion phase. Our results provide an incisive way to probe and understand phase stability in systems exhibiting complex spin topologies.

1:51PM G41.00012: Ultra-Short-Period Undulators for the Next Generation X-ray Free Electron Lasers*  BERKIN GÜREL (Presenter), Faculty of Engineering and Natural Sciences, Sabanci University, OMER POLAT, Faculty of Engineering and Natural Sciences, Bahcesehir University, NILAY GUNDUZ AKDOGAN, Faculty of Engineering, Piri Reis University, OZAN AKDOGAN, Faculty of Engineering and Natural Sciences, Bahcesehir University — There is a growing interest on the compact XFELs to be used in applications such as medical science (surgery, fat removal), material science and military. In order to build a compact XFEL, constructing an undulator with sub-millimeter period ($\lambda_u$) is mandatory. Many problems arise due to miniaturization of undulators; such as keeping the magnetic field high while still having a considerable gap to minimize beam scraping. In this work, RADIA program has been employed for the modeling of sub millimeter period undulators ($20 \, \mu m < \lambda_u < 400 \, \mu m$) with three different magnet configuration; namely Up-Down ($\uparrow\downarrow\uparrow\downarrow\ldots$), Halbach (Wiggler) ($\uparrow\downarrow\uparrow\downarrow\leftarrow\uparrow\ldots$) and Hybrid ($\rightarrow\uparrow\leftarrow\downarrow\rightarrow\ldots$). Effects of sub-millimeter undulator period and gap on the magnetic field pattern of the undulator have been discussed.

11:15AM G42.00001: Topological Magnetic-Spin Structures in Two-Dimensional Van Der Waals Cr$_2$Ge$_2$Te$_6^*$

MYUNG-GEUN HAN (Presenter), JOSEPH GARLOW, YU LIU, Brookhaven National Laboratory, HUIQIN ZHANG, Department of Electrical and System Engineering, University of Pennsylvania, DONALD DIMARZIO, MARK KNIGHT, NG Next, Northrop Grumman Corporation, CEDOMIR PETROVIC, Brookhaven National Laboratory, DEEP JARIWALA, Department of Electrical and System Engineering, University of Pennsylvania, YIMEI ZHU, Brookhaven National Laboratory — Long-range ferromagnetic order down to atomic layers provides an important degree of freedom in engineering two-dimensional (2D) materials and their heterostructure devices for spintronics, valleytronics and magnetic tunnel junction switches. Using direct imaging by cryo-Lorentz transmission electron microscopy we report that topologically nontrivial magnetic-spin states, skyrmionic bubbles, can be realized in exfoliated insulating 2D van der Waals Cr$_2$Ge$_2$Te$_6$. Due to the competition between dipolar interactions and uniaxial magnetic anisotropy, hexagonally-packed nanoscale bubble lattices emerge in the $ab$ plane by field cooling. Despite a range of topological spin textures arising due to pair formation and annihilation of Bloch lines, bubble lattices with single chirality are prevalent. Our observation of topologically-nontrivial homochiral skyrmionic bubbles in exfoliated vdW materials provides a new avenue for novel quantum states in atomically-thin insulators for magneto-electronic and quantum devices.

11:27AM G42.00002: Multiple ferromagnetic transitions and structural distortion in the van
der Waals ferromagnet VI₃ at ambient and finite pressures*  ELENA GATI (Presenter), YUJI
INAGAKI, Iowa State University, Ames Laboratory, TAI KONG, ROBERT J. CAVA, Princeton University, YUJI
FURUKAWA, SERGEY L. BUD’KO, PAUL C CANFIELD, Iowa State University, Ames Laboratory —
Magnetic van-der-Waals (vdW) materials are considered as promising candidate systems to
realize low-dimensional ferromagnetism in semiconductors. Here, we present a thermodynamic
(specific heat and magnetization) and microscopic NMR study on bulk single crystals of the
recently discovered ferromagnetic vdW material VI₃ at ambient and finite pressures [1]. Our
results show that VI₃ undergoes a structural transition, which is subsequently followed by two
ferromagnetic transitions at ambient pressure, giving rise to two distinct magnetically-ordered V
sites for low temperatures. Upon increasing pressure, the two magnetic transitions merge at p ~
0.6 GPa, and for even higher pressures (p ~ 1.25 GPa) merge with the structural transition. From
these observations, we infer that the magnetic structure in bulk single crystals of VI₃ is complex,
with magnetoelastic coupling being of significant importance.

11:39AM G42.00003: First principles Calculation of Dzyaloshinskii–Moriya interaction in 2D
magnetic van der Waals heterostructures   KAI HUANG (Presenter), DING-FU SHAO, EVGENY Y
TSYMBAL, University of Nebraska - Lincoln — Magnetic skyrmions are nanoscale spin textures
promising for next-generation spintronic applications. Recent studies have demonstrated that
skyrmions can be generated at the interface between a ferromagnetic layer and a nonmagnetic
heavy-metal-based layer due to a large Dzyaloshinskii–Moriya interaction (DMI) induced by
broken inversion symmetry and strong spin-orbit coupling. This usually requires multilayer
heterostructures with sizable thickness, which limit the nanoscale application. Recent discoveries
of two-dimensional (2D) magnets and the related van der Waals heterostructures offer the
possibility for skyrmions to emerge at the atomic scale layer thickness. Here, we predict the
emergence of a large DMI in bilayer magnetic van der Waals heterostructures composed of a 2D
ferromagnetic metal Fe₃GeTe₂ monolayer and a nonmagnetic monolayer. Based on first-
principles density functional theory calculations, we find that the DMI, the exchange coupling,
and the magnetic anisotropy of the magnetic van der Waals heterostructures can be modulated
by the interfacial proximity effect, leading to the tunable skyrmion behaviors. Our work indicates
the 2D magnetic van der Waals heterostructures are promising platforms for the skyrmion-based
spintronics.
11:51AM G42.00004: Realization of very large Dzyaloshinskii-Moriya interaction and skyrmion states in two-dimensional Janus manganese dichalcogenides* JINGHUA LIANG
(Presenter), Ningbo Institute of Materials Technology and Engineering, Chinese Academy of Sciences, WEIWEI WANG, HAIFENG DU, High Magnetic Field Laboratory, Chinese Academy of Sciences and University of Science and Technology of China, MAIRBEK CHSHIEV, Univ. Grenoble Alpes, CEA, CNRS, Spintec, ALBERT FERT, Unité Mixte de Physique, CNRS, Thales, University Paris-Sud, University Paris-Saclay, HONGXIN YANG, Ningbo Institute of Materials Technology and Engineering, Chinese Academy of Sciences — The Dzyaloshinskii-Moriya interaction (DMI), which only exists in noncentrosymmetric systems, is responsible for the formation of exotic chiral magnetic states. However, it is absent in most theoretically predicted and experimentally confirmed two-dimensional (2D) magnetic thin films so far. In this report, we perform first-principles calculations to demonstrate that significant DMI can be obtained in a series of Janus monolayers of manganese dichalcogenides MnXY (X/Y = S, Se, Te, X ≠ Y) in which the difference between X and Y on the opposites sides of Mn breaks the inversion symmetry. In particular, the DMI amplitudes of MnSeTe and MnSTe are comparable to those of state-of-the-art ferromagnet/heavy metal (FM/HM) heterostructures. Moreover, by performing Monte Carlo simulations, we find that the MnSeTe and MnSTe monolayers can host stable skyrmion states with the application of a moderate external magnetic field. The present results pave the way for new device concepts utilizing chiral magnetic structures in specially designed 2D ferromagnetic materials.

*We acknowledge the from the NNSF of China (11874059), Zhejiang Province NNSF of China (LR19A040002), and Horizon 2020 Research and Innovation Programme under grant agreement no. 785219 (Graphene Flagship).

12:03PM G42.00005: Topological Spin Textures in Janus Monolayers of Chromium Trihalides Cr(I,X)₃* CHANGSONG XU (Presenter), Univ of Arkansas-Fayetteville, JUNSHENG FENG, School of Physics and Materials Engineering, Hefei Normal University, YOUSRA NAHAS, SERGEI PROHORENKO, Univ of Arkansas-Fayetteville, HONGJUN XIANG, Physics, Fudan University, LAURENT BELLAICHE, Univ of Arkansas-Fayetteville — Topological magnetic states are promising for ultra-dense memory and logic devices. Recent progresses in two-dimensional magnets encourage the idea to realize topological states, such as skrmions and merons, in freestanding monolayers. However, monolayers such as CrI₃ lack Dzyaloshinskii-Moriya interactions (DMI) and thus do not naturally exhibit skyrmions/merons but rather a ferromagnetic state. Here we propose the fabrication of Cr(I,X)₃ Janus monolayers, in which the Cr atoms are covalently bonded to the underlying I ions and top-layer Br or Cl atoms. By performing first-principles calculations and Monte-Carlo simulations, we identify strong enough DMI, which leads to not only helical cycloid phases, but also to topologically nontrivial states, such as the intrinsic domain wall skyrmions in Cr(I,Br)₃ and the magnetic-field-induced bimerons in Cr(I,Cl)₃. Microscopic origins of such spin textures are revealed as well.

12:15PM G42.00006: Electrical excitation of superfluid- and string-like domain wall modes in layered van der Waal antiferromagnets*  MOHAMMAD MUSHFIQUR RAHMAN (Presenter), AVINASH RUSTAGI, Electrical and Computer Engineering, Purdue University, YAROSLAV TSERKOVNYAK, Physics & Astronomy, University of California, Los Angeles, PRAMEY UPADHYAYA, Electrical and Computer Engineering, Purdue University — Efficient excitation of magnons (collective spin excitation in magnetically ordered materials) has been a limiting factor in designing low-dissipation magnonic devices. The recent emergence of low-dimensional van der Waal magnets [such as CrI3] with demonstrated electrical control of magnetic order [Nature Mat. 17, 406 (2018)] opens up new opportunities in the field of magnonics. Motivated by these developments, we theoretically demonstrate the electrical excitation of superfluid- and string-like modes harbored by the antiferromagnetically coupled domain walls of bilayer CrI3. Furthermore, we show that dc magnetic fields provide a handle for selectively exciting the mode of choice.

*We acknowledge NSF grant ECCS 1810494

12:27PM G42.00007: Merons in Monolayer CrCl₃*  XIAOBO LU (Presenter), RUIXIANG FEI, LI YANG, Washington University, St. Louis — Noncollinear spin textures in low-dimensional magnetic systems such as skyrmions, magnetic bobbles and merons have been studied for decades with their extraordinary properties derived from their chirality and topological nature. Here, using first principles and Monte Carlo simulations, we propose that monolayer chromium chloride (CrCl₃) can be a promising candidate to observe paired magnetic vortex type and antivortex type topological defects, which are so-called merons. Through this paper, we demonstrate the existence of vortex and antivortex type meron pairings within the low temperature range (below 5K). Moreover, higher-order combinations of those meron pairs which are similar to the “quadrupole” excitations are also identified. Finally, including the in-plane and out-of-plane external magnetic field, we show the robustness of merons’ pairing and a rich phase space to tune the hybridizations between the ferromagnetism and meron excitations.

*The work at WUSTL are supported by the National Science Foundation (NSF) CAREER Grant No. DMR-1455346 and the Air Force Office of Scientific Research (AFOSR) grant No. FA9550-17-1-0304. The computational resources have been provided by the Stampede of TeraGrid at the Texas Advanced Computing Center (TACC) through XSEDE.
12:39PM G42.00008: Anomalous spin-Hall effect in 2D Cr-based materials* YURI DAHNOVSKY, ANDREI S. ZADOROZHNYYI (Presenter), Univ of Wyoming — We study the THE in various systems on 2D magnetic materials (CrI$_3$, CrCl$_3$, and CrBr$_3$). From the estimations a skyrmion size is about 30-40 nm. The computations of a spin Hall effect and magnetoresistance require the calculations of the nonequilibrium distribution function, which we will determine from the kinetic Boltzmann equation. The distribution function describes by a 4 × 4 matrix because of different spin projections and the spin-dependent momenta of conducting electrons. The matrix elements contain various parameters such as effective masses, exchange constants, etc., that will be found from the first principle calculations. The reason why such system exhibit topological Hall effect is because the scattering transition probability matrix has an antisymmetric part with respect to the scattering angle. The scattering asymmetry acts as an effective magnetic field, which sign can be either the same for both spin projections of an incident electron, hence leading to a topological charge Hall effect, or opposite for different electron spin projections, leading to the topological spin Hall effect.

*We acknowledge a grant (No. DE-SC0020074 from the US Department of Energy

12:51PM G42.00009: Skyrmions in TMD-based antiferromagnetic triangular lattices* ALDO RAELIARJAONA (Presenter), WUZHANG FANG, University of Nebraska - Lincoln, PO-HAO CHANG, Physics, University of Texas at El Paso, KIRILL BELASHCHENKO, ALEXEY KOVALEV, University of Nebraska - Lincoln — We study the adsorption of magnetic transition metal atoms (Cr, Mn, Fe, and Co) on top of a TMDs such as MoS2 or WSe2, where the transition metal atoms form a triangular lattice. We conducted Monte Carlo simulations and analytical studies to obtain and characterize the magnetic ground state and determine the phase diagram for systems with AFM triangular lattice. The Heisenberg exchange parameters, single-ion anisotropy constants, and Dzyaloshinskii-Moriya vectors were extracted from first-principles density functional calculations. We found that without external magnetic field spirals are the most stable textures. Furthermore, we demonstrate the possibility of stabilizing antiferromagnetic skyrmion lattices living on 3 sublattices in such system under the influence of an external magnetic field.

*This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award No. DE-SC0014189.
Magnetically coupled nanomagnets have many potential applications including non-volatile memories, logic gates and sensors. In order to realize functional 2-D networks of coupled nanoscale magnetic elements such as those used for nanomagnet logic [1] and artificial spin ice [2], it is desirable to engineer effective lateral magnetic couplings in a controllable way. Up to now, this has been achieved by exploiting the long-range dipolar interaction. However, the dipolar interaction is non-local and scales inversely with the magnet volume, so limiting its use in applications involving nanometer sized structures and thin films. In this work, we demonstrate an alternative method to control the lateral coupling between adjacent magnetic nanostructures [3] based on the interfacial Dzyaloshinskii-Moriya interaction (DMI). In particular, we have patterned regions with in-plane (IP) and out-of-plane (OOP) magnetic anisotropy in a magnetic element using selective oxidation of Pt/Co/Al films, and the magnetization in the OOP and IP parts of the islands are chirally coupled via DMI arising from the Pt underlayer, giving either $\downarrow \rightarrow$ or $\uparrow \leftarrow$ configurations.

We have exploited this concept for various applications. For example, we have created stable synthetic lateral antiferromagnets, skyrmions with different numbers of IP rings and artificial spin ices based on a square lattice and kagome lattice. In addition, we have demonstrated field-free current-induced switching between multistate magnetic configurations in the chirally coupled thin-film nanomagnets via spin-orbit torques. Our work therefore provides a platform to design tailor-made arrays of correlated nanomagnets with a future perspective to achieve all-electric control of planar logic gates and memory devices.

**1:39PM G42.00011: Tuning Magnetic Order with Iron Intercalation in Transition Metal Dichalcogenides**  
CAOLAN JOHN (Presenter), Physics, Massachusetts Institute of Technology, SPENCER DOYLE, Physics, Harvard University, ERAN MANIV, JAMES ANALYTIS, Physics, University of California, Berkeley — The transition metal dichalcogenides are a class of two-dimensional materials currently under intense research due to their attractive electronic properties. Through the process of intercalation, magnetic atoms can be inserted between the layers of these materials to introduce long range magnetic order, enabling exploration of magnetism in these systems. I will present magnetization and thermodynamic measurements that indicate antiferromagnetic order in iron intercalated NbS$_2$. Crucially, we can use intercalation to control the strength of an emergent spin glass state below intercalation values of $x = 1/3$ in Fe$_x$NbS$_2$. The cooperation between this glassy phase and the antiferromagnetic order allow for the generation of substantial bias fields in the system.

*Caolan John was supported by the Haas Scholars Program and by the Gordon and Betty Moore Foundation's EPIQS Initiative through Grant GBMF4374

**1:51PM G42.00012: Electrical switching in a magnetically intercalated transition metal dichalcogenide**  
ERAN MANIV (Presenter), NITYAN NAIR, CAOLAN JOHN, SPENCER DOYLE, JOSEPH ORENSTEIN, JAMES ANALYTIS, physics, University of California, Berkeley — Advances in controlling the correlated behavior of transition metal dichalcogenides have opened a new frontier of many-body physics in two dimensions. A field where these materials have yet to make a deep impact is antiferromagnetic spintronics – a relatively new research direction promising technologies with fast switching times, insensitivity to magnetic perturbations, and reduced crosstalk. Here, we present measurements on the intercalated TMD Fe$_{1/3}$NbS$_2$ which exhibits antiferromagnetic ordering below 42K. We find that remarkably low current densities of order $10^4$ A/cm$^2$ can reorient the magnetic order, which can be detected through changes in the sample resistance, demonstrating its use as an electronically-accessible antiferromagnetic switch. Fe$_{1/3}$NbS$_2$ is part of a larger family of magnetically intercalated TMDs, some of which may exhibit switching at room temperature, forming a platform from which to build tunable antiferromagnetic spintron devices.

2:03PM G42.00013: Evidence for a pressure-induced gapped spin-liquid ground state in a coupled ladder antiferromagnet \( \text{C}_9\text{H}_{18}\text{N}_2\text{CuBr}_4 \)†

TAO HONG (Presenter), Oak Ridge National Lab, TAO YING, Harbin Institute of Technology, QING HUANG, University of Tennessee, Knoxville, SACHITH DISSANAYAKE, Duke University, YIMING QIU, National Institute of Standards and Technology, MARK M TURNBULL, Clark University, ANDREY PODLESNYAK, YAN WU, HUIBO CAO, DAVID TENNANT, Oak Ridge National Lab, KAI SCHMIDT, Universität Erlangen-Nürnberg, STEFAN WESSEL, RWTH Aachen University — Here we present a comprehensive neutron scattering study on a spin-1/2 coupled ladder antiferromagnet \( \text{C}_9\text{H}_{18}\text{N}_2\text{CuBr}_4 \) (DLCB for short) under applied hydrostatic pressure. In DLCB, the inter-ladder coupling is sufficiently strong to drive the system to the long-range antiferromagnetic ordering phase below \( T_N=2 \) K [1]. Analysis of the spin Hamiltonian suggests that DLCB is close to the quantum critical point in two dimensions at ambient pressure and zero field [2]. Single-crystal neutron diffraction measurements under pressure suggest that the magnetic order breaks down above a critical pressure \( P_c \sim 1.0 \) GPa. By contrasting with quantum Monte Carlo calculations of the dynamic structure factor, the follow-up inelastic neutron scattering study above \( P_c \) reveals evidence of a gapped spin-liquid phase with the \( Z_2 \) topological order, characterized by excitation spectra of fully gapped visons and deconfined spinons.

Session G43 DCOMP DAMOP DCMP: Precision Many-Body Physics IV: Novel Methods and Algorithms 702 - Evgeny Kozik, Kings Coll - Tag(s): Focus
11:15AM G43.00001: The variational and diagrammatic quantum Monte Carlo approach to the many-electron problem* [Invited] KUN CHEN (Presenter), KRISTJAN HAULE, Rutgers University, New Brunswick — Two of the most influential ideas developed by Richard Feynman are the Feynman diagram technique and his variational approach. Here we show that combining both, and introducing a diagrammatic quantum Monte Carlo method, results in a powerful and accurate solver to the generic solid state problem, in which a macroscopic number of electrons interact by the long-range Coulomb repulsion. We apply it to the quintessential problem of solid state, the uniform electron gas, which is at the heart of the density functional theory success in describing real materials, yet it has not been adequately solved for over 90 years. Our method allows us to calculate numerically exact momentum and frequency resolved spin and charge response functions. This method can be applied to a number of moderately interacting electron systems, including models of realistic metallic and semiconducting solids.

*This work is supported by the Simons Collaboration on the Many Electron Problem and NSF DMR-1709229.

11:51AM G43.00002: Modern diagrammatic many body techniques.* [Invited] RICCARDO ROSSI (Presenter), Simons Foundation, FEDOR SIMKOVIC, MICHEL FERRERO, Ecole Polytechnique — In this talk I will discuss recent progress on the development of unbiased diagrammatic techniques for strongly-correlated many-body systems. The formalism we have developed allows to elegantly and efficiently encode the fundamental structure of quantum-many theory using renormalized expansions as the building block. Within this framework it is easy to incorporate, for instance, well-established many-body approximations like Dynamical Mean Field Theory as the starting point of a perturbative expansion. In particular, I will present state-of-the-art results in two and three dimensional Fermi-Hubbard models away from half filling in the non-perturbative regime.

*Simons Foundation Many Electron Collaboration.

12:27PM G43.00003: Faster-than-the-Clock Quantum Monte Carlo* FEDOR SIMKOVIC (Presenter), MICHEL FERRERO, CPHT, Ecole Polytechnique, RICCARDO ROSSI, CCQ, Flatiron Institute — In this talk we present a way to naturally merge and extend Monte Carlo acceleration techniques with the sampling of set functions, which can be viewed as the partition function of a bosonic system. The algorithm is particularly suited for the Connected Determinant Diagrammatic Monte Carlo algorithm (CDet) as well as its extensions and generalizations. Our proposed algorithm is rejection-free and allows for variance and autocorrelation time reduction by making use of the exponential information contained in the full set structure. Finally, we present numerical results for the two-dimensional Hubbard model obtained with this technique.

*Simons Collaboration on the Many Electron Problem
12:39PM G43.00004: A light weight regularization for wave function parameter gradients in quantum Monte Carlo  SHIVESH PATHAK (Presenter), LUCAS WAGNER, University of Illinois at Urbana-Champaign — The parameter derivative of the expectation value of the energy is a key ingredient in variational quantum Monte Carlo (VMC) wave function optimization methods. A naive Monte Carlo estimate of this derivative suffers from an infinite variance which inhibits the efficiency of optimization methods which rely on a stable estimate of the derivative. In this work we derive a simple regularization of the naive estimator which is easy to implement and has a negligible bias. This regularization is trivial to implement in a standard VMC code without sampling complex distributions and it can be extrapolated to zero bias without extra computation.

12:51PM G43.00005: Measuring Rényi Entanglement Entropies in Lattice Worm Algorithm Quantum Monte Carlo*  EMANUEL CASIANO-DIAZ (Presenter), Univ of Vermont, CHRIS M HERDMAN, Physics, Middlebury College, ADRIAN DEL MAESTRO, Univ of Vermont — In this talk we report on an extension of lattice worm algorithm quantum Monte Carlo that allows for the exact simulation of interacting bosons at zero temperature. We will discuss the implementation of the SWAP technique within the lattice path integral framework that provides access to novel estimators, including the Rényi entanglement entropies without complete knowledge of the density matrix. This technology can be used to probe the scaling of entanglement between spatial subregions and may be useful in understanding the quantum information encoded in ultracold lattice gases that can be probed via a quantum gas microscope.

*This work was supported in part by the NSF under Grant No. DMR-1553991. Computations were performed on the Vermont Advanced Computer core supported in part by NSF Grant No. OAC-1827314.

1:03PM G43.00006: Diagrammatic Monte Carlo for Molecules  JIA LI (Presenter), MARKUS WALLERBERGER, EMANUEL GULL, Univ of Michigan - Ann Arbor — Electron correlations in chemical systems give rise to a wide range of interesting physical properties. Although traditional mean-field quantum chemical algorithms can reliably calculate ground state observables in many cases, finite temperature and spectral properties are only accessible with explicit inclusion of electron correlations. Diagrammatic Monte Carlo (DiagMC), which expands the physical observable in terms of connected Feynman diagrams and samples the resulting series stochastically, is a powerful technique for studying electron correlations and does not suffer from numerical sign problem which worsens with increasing system size. Recent developments in DiagMC algorithms have greatly improved their numerical efficiency. In this talk, I aim to introduce our DiagMC implementation for multi-orbital systems, and present our results when it is applied to realistic molecular systems.
1:15PM G43.00007: Hybridizing Pseudo-Hamiltonians and Non-local Pseudopotentials in Diffusion Monte Carlo*  
JARON KROGEL (Presenter), FERNANDO REBOREDO, Oak Ridge National Lab — Projector quantum Monte Carlo (QMC) methods are among the most accurate many body techniques to query the properties of the electronic ground state. Due to computational efficiency, non-local pseudopotentials (NLPPs) are used in QMC for all but light elements. This comes at the price of localization approximations (LAs) that can degrade total accuracy. An alternate pseudo-Hamiltonian (PH) approach that does not require LA was considered early in the QMC history of core pseudization [PRL 62 2088 (1989)], but was not adopted as producing adequate potentials was difficult. In this work, we explore the hybridization of NLPPs and PHs in an attempt to reduce the non-local components. For 3d transition metals we show that hybrid PHs can be as accurate as NLPPs, but with a much smaller non-local part. We find that a simple approach to partitioning scattering channels between the NLPP and PH components does not lead to a reduction of localization error, but instead aligns the behavior of the prevailing locality and T-moves approximations. Reasons for this behavior and possible avenues for direct minimization of localization error are discussed.

1:27PM G43.00008: Excitations with Diffusion Monte Carlo: a bottom-up approach.*  
FERNANDO REBOREDO (Presenter), Oak Ridge National Lab — The applications of diffusion Monte Carlo (DMC) have been largely focused on properties of the ground state. As a result, high quality methods to obtain and optimize the ground-state trial wavefunctions are available. However, since much of the phenomena in Solid State Physics is governed by low energy excitations, attempts to extend DMC for the calculations of excited states properties are also documented in the literature. Most of those attempts focus on the direct calculation of excitations. In this talk we will discuss an alternative approach: how to extract excited state properties as an observable of the many-body ground state evaluated within a standard DMC method. The theory will be tested in a model system and compared with exact solutions. The potential limitations of this indirect approach for large systems of interest for real material problems will be discussed.

*Research supported by the Materials Science and Engineering Division, Basic Energy Sciences, Department of Energy.

1:39PM G43.00009: Diagrammatic Monte Carlo for real materials*  
SAM AZADI (Presenter), Physics, King's College London, ARKADIY DAVYDOV, Physics, University of Zurich, EVGENY KOZIK, Physics, King's College London — We present a systematic method for reaching beyond the GW approximation by Diagrammatic Monte Carlo (DiagMC) for first-principle simulations of real materials. DiagMC is used to provide an efficient estimation of higher-order self-energy and polarisability diagrams to achieve a controlled solution for ab initio Hamiltonians.

*This work is supported by the Simons Foundation as a part of the Simons Collaboration on the Many Electron Problem.
1:51PM G43.00010: Evaluation of arbitrary Feynman graphs via algorithmic methods.*
JAMES P. F. LEBLANC (Presenter), Physics, Memorial U. of Newfoundland — Feynman diagrammatics is a powerful tool for the study of correlated electron systems. However, the formulation of diagrams in terms of Matsubara frequencies is not well suited to numerical computations due to an intrinsic inability to evaluate the unbounded Matsubara frequency integrals. In this talk we present an algorithm for fully symbolic evaluation of arbitrary Feynman diagrams that overcomes this issue, and many others. Further, from this perspective of analytics we identify a procedure for high order diagrams which allows for the optimal reduction of the sign problem. This is accomplished via invariant transformations that allow us to group diagrams whose integrands are analytically equal or analytically cancel.

2:03PM G43.00011: Diagrammatic Monte Carlo for attractively interacting fermions*
GABRIELE SPADA, Laboratoire Kastler Brossel, Ecole Normale Supérieure, RICCARDO ROSSI, Center for Computational Quantum Physics, Flatiron Institute, TAKAHIRO OHGOE, Department of Applied Physics, Waseda University, FEDOR SIMKOVIC, MICHEL FERRERO, Centre de Physique Théorique, Ecole Polytechnique, KRIS VAN HOUCKE, Laboratoire de Physique de l'ENS, Ecole Normale Supérieure, FÉLIX WERNER (Presenter), Laboratoire Kastler Brossel, Ecole Normale Supérieure — A major long-standing goal is the precise computation of properties of interacting many-fermion systems. By evaluating connected Feynman diagrams, the diagrammatic Monte Carlo approach works directly for infinite system size. Thanks to efficient Monte Carlo algorithms, one can reach high enough orders to observe convergence up to a small error bar, provided the diagrammatic series is sufficiently well behaved, if necessary after applying a divergent-series resummation procedure. A crucial ingredient is to use dressed propagators or vertices as building blocks of the diagrams, and to expand around an appropriate starting point. The functional integral formalism allows to justify the validity of such reorganized expansions and their resummability, even for a zero convergence radius. I will present results for two cases of experimental relevance: The normal phase of the unitary Fermi gas, and the superfluid phase of the attractive Hubbard model.

Session G44 DCOMP: Van Der Waals Interactions in Molecules, Materials, and Complex Environments II 704 - Robert Distasio, Cornell University - Tag(s): Focus
**11:15AM G44.00001: The Role of Correlation Effects in Non-Valence Anions** [Invited]
KENNETH JORDAN (Presenter), SHIV UPADHYAY, ARAILYM KAIRALAPOVA, Univ of Pittsburgh — Non-valence anions are especially challenging for traditional electronic structure methods due to the need to use very large basis sets and to include high-order electron correlation effects. The most widely studied class of non-valence anions are dipole-bound anions for which the excess electron binds in the Hartree-Fock approximation provided a sufficiently flexible basis set is used. Even more challenging are non-valence correlation bound (NVCB) anions for which the excess electron does not bind in the absence of dispersion-like correlation effects between the excess electron and the electrons of the molecule or cluster. In my talk, ab initio and model Hamiltonian approaches for characterizing correlation effects in dipole-bound and NVCB anions will be analyzed. Although those anions have very extended charge distributions, we find that the dominant correlation contributions to the electron binding energies are shorter-range in nature than is generally believed.

**11:51AM G44.00002: Attracting Opposites: Promiscuous Ion-π Binding in the DNA Nucleobases**
BRIAN ERNST (Presenter), KA UN LAO, ANDREW G. SULLIVAN, ROBERT DISTASIO, Cornell University — Ion-π interactions between the face of a molecular π-system and a cation or anion are among the strongest non-covalent interactions known, with applications throughout biochemistry and structural biology, host-guest chemistry, as well as enzyme kinetics and organocatalysis. In this work, we perform a detailed theoretical case study of ion-π interactions in the DNA/RNA nucleobases by first demonstrating that these π-systems are promiscuous ion-π binders with the versatility to bind both cations (Li⁺/Na⁺) and anions (F⁻/Cl⁻). Using a novel SAPT-based energy decomposition analysis, we uncover the different physicochemical driving forces underlying the formation of cation- and anion-π complexes, as well as the crucial role played by charge penetration effects in anion-π systems. In doing so, a unified view of these rather distinct non-covalent binding motifs emerges with the finding that both cation- and anion-π complexes are strongly stabilized by an essentially ring-independent potential that can only be overcome by substantially unfavorable electrostatics. Interestingly, the analysis presented herein demonstrates that π-systems have an inherent propensity to bind both cations and anions, thereby implying that promiscuous ion-π binding should be quite common in nature.
12:03PM G44.00003: NENCI-2020: A Large Benchmark Non-Equilibrium Non-Covalent Interaction Database with Emphasis on the Repulsive Wall  ZACHARY SPARROW (Presenter), BRIAN ERNST, PAUL JOO, KA UN LAO, ROBERT DISTASIO, Cornell University — In this work, we present NENCI-2020: a benchmark database of non-equilibrium non-covalent interaction energies for a large and diverse set of intermolecular complexes. NENCI-2020 contains ~8,000 interaction energies computed with CCSD(T)/CBS, and includes 7 non-equilibrium intermolecular distances (spanning 0.7-1.1x the equilibrium separation) and 8 non-equilibrium angles (per distance) for ~150 complexes. Using SAPT2+, we demonstrate that NENCI-2020 contains a diverse array of intermolecular binding motifs, making this database well suited for testing and developing next-generation force fields, density functional theory (DFT) approximations, quantum chemical (QC) methods, and machine-learning based approaches. This is followed by a critical assessment of ~75 dispersion/van der Waals-corrected DFT and QC methods, in which we find that most approaches can describe interaction energies for equilibrium and farther-than-equilibrium configurations with chemical accuracy (i.e., to within 1 kcal/mol). More importantly, we find that nearly all methods suffer from a rapid and systematic increase in error as the intermolecular distances become small, thereby suggesting that more work will be needed to describe intermolecular potential energy surfaces with uniform accuracy.

12:15PM G44.00004: Ab initio evaluation of complexation energies for cyclodextrin–drug inclusion complexes  KENJI OQMHULA (Presenter), KENTA HONGO, RYO MAEZONO, TOM ICHIBHA, Japan Adv Inst of Sci and Tech — Within the framework of density functional theory (DFT), an appropriate incorporation of van der Waals (vdW) into the exchange correlation (XC) functional is important to accurately predict complexation energies of noncovalent systems. This point has not been widely verified in large host-drug systems. Here we benchmarked various DFT to evaluate complexation energies of host-guest complexes, three types of β-cyclodextrins and plumbagin (known as anti-cancer drug). We modeled these systems as follows: (1) DFT geometry optimization of individual guest and hosts, (2) their docking conformation search based on genetic algorithm with semi-empirical simulations, and (3) DFT geometry optimization of the docking system. Then single-point energy calculations were performed to evaluate complexation energies. Furthermore, we applied DMC (diffuse Monte Carlo) to validate the DFT results. We found M06-2X-D3 and CAM-B3LYP-D3 give almost the same energies for all the cases and they are both consistent with DMC within the error bar. From these results, we concluded that a proper incorporation of vdw and long-range exchange corrections into XC functionals is essential for describing the cyclodextrin-plumbagin systems.
Many-body dispersion effects and plasmonic correlations in the catalytic synchronization of a DNA-enzyme complex  MATTEO GORI (Presenter), Quantum Biology Laboratory, Howard University, Washington, DC, MARTIN STOEHR, ALEXANDRE TKATCHENKO, Physics and Materials Science Research Unit, University of Luxembourg, PHILIP KURIAN, Quantum Biology Laboratory, Howard University, Washington, DC — Long-range van der Waals dispersion forces could play a significant role in explaining the action of certain restriction enzymes inducing DNA double-strand breaks [J. Theor. Biol. 2016, 391, 102-112]. In particular, dipolar interactions among spatially separated nucleotides and enzymatic molecular subunits may be responsible for long-range synchronization of quantum electronic density fluctuations. Zero-point modes of such plasmon-like oscillations may promote double-strand breakage, in lieu of external chemical energy from ATP. Our analysis of Many-Body Dispersion (MBD) effects in the catalytic behavior of EcoRI, a sequence-specific DNA-targeting enzyme used widely in genomic science, offers clues for more refined investigations of the collective electron fluctuations (plasmon) in complex (bio)molecular systems [Chem. Soc. Rev. 2019, 48, 4118]. We present analysis of these MBD eigenmodes applied to EcoRI at different steps along the catalytic trajectory, including entropic measures of the degree of collectivity of each mode (i.e., its vectorial distribution in the atomic site basis) and other quantum information metrics, to understand the delocalization properties in Hilbert space and their implications for distant “plasmonic allostery” in 3+1-dimensional physical space.
Inversion Symmetry Breaking Probed by X-ray Absorption Spectroscopy in H-bonded Organic Ferroelectric Crystal

FUJIE TANG (Presenter), Department of Physics, Temple University, XUANYUAN JIANG, Department of Physics and Astronomy, University of Nebraska, HSIN-YU KO, Department of Chemistry, Princeton University, JIANHANG XU, Department of Physics, Temple University, MEHMET TOPSAKAL, Center for Functional Nanomaterials, Brookhaven National Laboratory, GUANHUA HAO, Department of Physics and Astronomy, University of Nebraska, ALPHA T. N’DIAYE, Advanced Light Source, Lawrence Berkeley National Laboratory, PETER A DOWBEN, Department of Physics and Astronomy, University of Nebraska, DEYU LU, Center for Functional Nanomaterials, Brookhaven National Laboratory, XIAOSHAN XU, Department of Physics and Astronomy, University of Nebraska, XIFAN WU, Department of Physics, Temple University — Molecular ferroelectrics (FE) based on ordering hydrogen bonds have potentially high electric polarization and ordering temperature compared with the conventional oxide FE materials. In particular, croconic acid (C5O5H2) with FE polarization of 30 μC/cm², plays a prototype of ferroelectric organic molecular solid, whose electric polarization is generated by proton transfer. We carry out X-ray absorption spectroscopy experiment at oxygen K-edge in croconic acid crystal. The experimental spectrum is well reproduced by the electron-hole excitation theory simulations from configuration generated by ab initio molecular dynamics simulation. When inversion symmetry is broken in ferroelectric state, the hydrogen bonding environment on the two bonded molecules become inequivalent. Such a difference is sensitively probed by the bound excitation in the pre-edge, which are strongly localized on the excited molecules. Our analysis shows that a satellite peak in the pre-edge will emerge at higher excitation energy which serves as a clear signature of ferroelectricity in the material.

This work was primarily supported by National Science Foundation through Awards No. DMR-1552287.

van der Waals Phonons in Molecular Crystals

SOMAYEH KHAZAEI (Presenter), ALEXANDRE TKATCHENKO, University of Luxembourg Limpertsberg — Low-frequency terahertz (THz) vibrations are ubiquitous in molecular materials throughout chemistry and biology [e.g. PRL 113, 055701; PRL 119, 097404]. Such delocalized vibrations play a key role in many phenomena, including entropic stabilization of molecular crystal polymorphs, protein folding, and signaling. However, our understanding of mechanisms behind THz vibrations in molecular materials is far from complete. Here we study a range of molecular crystals with DFT including many-body treatment of van der Waals (vdW) dispersion interactions (DFT+MBD). We find that THz vibrations are very sensitive to the correct treatment of electrostatic effects in DFT and explicit quantum-mechanical treatment of vdW interactions. We discuss a way to categorize vibrational modes in the THz range and show that these vibrations are crucial to achieve a better understanding of molecular materials.
First-principles studies of small molecule absorption kinetics in diamine-appended metal-organic frameworks

ALEX SMITH (Presenter), University of California, Berkeley, JEFFREY B NEATON, University of California, Berkeley; Molecular Foundry, Lawrence Berkeley National Laboratory; Kavli Energy Nanosciences Institute at Berkeley — Recently, a family of diamine-appended metal-organic frameworks (MOFs) has demonstrated selective and tunable adsorption via novel reversible non-Langmuir stepped isotherms, making them promising for carbon capture applications. Here, we use first principles van der Waals-corrected density functional theory calculations, as well as molecular dynamics and computations of NMR chemical shifts, to understand the structure, kinetics, and selectivity associated with the stepped isotherms in environments relevant to flue gas conditions. We compare binding energies with experiments, and predict intermediate and final structures to understand the measured isotherms. We focus on the role that SO2, a component of flue gas, plays in degrading MOF CO2 adsorption through studying SO2 binding energies and how SO2 disrupts the kinetics of CO2 adsorption. This work is supported by DOE, and computational resources are provided by NERSC.

Long-range Correlation Energy in the Interaction of Molecules with Surfaces

ALINA UMERBEKOVA (Presenter), MICHELE PAVANELLO, Rutgers University, Newark — By exploiting the fluctuation-dissipation theorem of DFT and a formally exact decomposition of the density-density linear response function evaluated at imaginary frequency, subsystem Density Functional Theory makes an excellent platform for developing non-local long-range correlation energy functionals [1,2]. We present a computational protocol to extract embedded C6 coefficients for molecules surrounded by complex environments from a real-time subsystem TDDFT simulation [3]. The C6 coefficients fully account for environmental screening effects through the many-body response [4]. We showcase a pilot calculation of the C6 coefficient of Benzene adsorbed on monolayer MoS2 and we show a surface enhancement of the van der Waals interaction between two benzene molecules nearby a MoS2 surface of 11 meV compared to the interaction estimated from C6 coefficients derived from isolated benzene molecules.

1:27PM G44.00010: Reproducibility of Molecular Adsorption Potential Energy Surfaces

LUKAS HÖRMANN (Presenter), ANDREAS JEINDL, OLIVER T. HOFMANN, Institute of Solid State Physics, Graz University of Technology — The adsorption of molecules on surfaces depends on a variety of mechanisms: Covalent bonds, charge transfer and van-der-Waals (vdW) interactions shape the potential energy surface (PES), making it key to understanding molecule-substrate interfaces. To describe these interfaces with density functional theory, one can choose from many different exchange correlation functionals and vdW correction schemes. To explore how robust the PES is in relation to the choice of method, we present a benchmark of common local, semi-local and non-local functionals in combination with various vdW corrections for perylenetetracarboxylic dianhydride (PTCDA) on Ag(111), one of the most frequently studied system.

Using only about 50 DFT calculations as input data, an in-house developed Gaussian process regression algorithm generates PESs with DFT accuracy. This allows us to analyze the PES's features, such as positions and energies of minima and saddle points, in detail. Comparing the results from different exchange correlation functionals allows us to identify trends and differences between the approaches. Finally, we compare key features, such as local minima, with experimental data to determine a “quality seal” for the different functionals and vdW corrections.

Session G45 DCOMP DCP: Modeling the electrochemical interface and aqueous solutions II 706 - Luana Pedroza, Univ Federal do ABC - Tag(s): Focus
First-principles electrochemistry with grand-canonical DFT and continuum-solvation methods

RAVISHANKAR SUNDARARAMAN (Presenter), Materials Science and Engineering, Rensselaer Polytechnic Institute — First-principles calculations combining density-functional theory (DFT) and continuum solvation models have been highly successful in enabling the theoretical design of liquid-phase catalyst materials. The application of such methods to heterogeneous catalysis in electrochemical solid-liquid interfaces has however been far more challenging for two reasons. First, conventional continuum solvation methods designed for finite molecular systems are not readily applicable to solid-liquid interfaces with metal or oxide surfaces. Second, processes at these interfaces continuously exchange electrons with the electrode, which makes the charge states of the surface difficult to determine.

I will present recent developments in continuum solvation methods that enable simultaneously accurate treatment of solid surfaces and molecules in electrochemical interfaces. Additionally, by automatically equilibrating charge at a fixed electrochemical potential, new 'grand-canonical DFT' algorithms and software (JDFTx) facilitate realistic description of processes in these interfaces. Together, these methods enable first-principles prediction of electro- and photo-catalysis mechanisms for energy conversion, and of the surface structures and dynamics in battery materials. With clean prototypical electrochemical measurements as a benchmark, I will outline the present capabilities, pending challenges and necessary future developments in first-principles electrochemistry.

The nanoscopic structure of Pt-water electrified interface under applied potential

CLOTILDE CUCINOTTA (Presenter), Imperial College London — In this talk I will introduce some issues connected with the simulation of electrified interfaces at the nanoscale focusing in particular on modelling the effect of an applied potential to an electrochemical cell. I will present a new methodology to model charged electrodes and highlight some recent progress in the simulation of the double layer of the fundamental Pt-water interface and its response to changes of potential applied to the cell. We reveal that the metal/surface charging cannot be described using a traditional simple capacitor model and that the double layer nanoscopic structure, mass density and charge distribution, strongly depend on the applied potential.

*EP/P033555/1 Towards a Parameter-Free Theory for Electrochemical Phenomena at the Nanoscale (NanoEC)
In this presentation, we will discuss how a combination of ab-initio simulations and in-situ characterizations could be used to access to such information and how one could reduce uncertainty in interpreting the experimental data. The key is to use ab-initio simulations as link between multiple observables that are not linearly dependent each other, which may be used to avoid a misinterpretation due to accidental agreement on one observable. We will show the examples based on oxidation of III-V semiconductor surfaces induced by water and oxygen.

12:15PM G45.00004: Activating 2D materials for hydrogen evolution reaction (HER) by electron doping*  NAIRWIT KARODAK (Presenter), OLIVIERO ANDREUSSI, Physics, University of North Texas — The two-dimensional materials have emerged as an effective electrocatalysts for Hydrogen evolution reaction in the recent few decades.[1] However, the database of such materials is limited so far mostly to family of transition metal dichalcogenides and MXenes. Moreover, majority of these need prior activation by defect engineering or elemental doping. In this presentation, we show an electron doping pathway to enhance the electro-catalytic efficiency of two-dimensional material surfaces towards HER. A high-throughput computational scheme has been employed, starting from a large computational database of the easily exfoliable compounds.[2] By exploiting continuum embedded density functional theory and Grand Potential Simulation techniques, we studied the H⁺ electrosorption reaction thermodynamics and the aqueous stability of the 2D materials at different applied potentials and pH.[3,4] Our results allow to identify some promising materials, which show potential catalytic activity and considerable stability at reducing potentials and acidic pH.

12:27PM G45.00005: Probing Pseudocapacitive response of MXene electrodes for energy storage from first principles*  FRANCISCO MARQUES DOS SANTOS VIEIRA (Presenter), Pennsylvania State University, YASUAKI OKADA, Murata Manufacturing, NATHAN D KEILBART, JAMES GOFF, Pennsylvania State University, KOSUKE SHIRATSUYU, Murata Manufacturing, ISMAILA DABO, Pennsylvania State University — Pseudocapacitive devices are able to store and release electrical energy by virtue of the rapid and reversible redox reactions which occur at the electrode surfaces. The family of transition metal carbides and nitrides, MXenes, show promise as pseudocapacitive electrodes. As the performance, power and energy densities, of the pseudocapacitive device is predicated on the quantity of lithium-ion adsorption onto the surface of the MXene, we are interested in the effects of MXene composition and solution properties on this phenomenon. We perform voltage-dependent cluster expansions to study reversible lithium-ion adsorption in realistic environments. The cluster expansions are fit with semi-local density functional calculations in implicit solvent. Preliminary results show that lithium-ion pseudocapacitance is sensitive to the dielectric constant of the solution and extent of surface electrification through electrochemical double layer capacitance. Our results also suggest that solvents with higher lithium reduction potentials that stabilize the lithium-ions in solution can extend the potential window of the pseudocapacitive electrode.

*MuRata Manufacturing
12:39PM G45.00006: Understanding water/silicon carbide interfaces using first principle simulations

FILIPPO SAVAZZI (Presenter), GIANCARLO CICERO, Dipartimento di Scienza Applicata e Tecnologia, Politecnico di Torino, MARCO GOVONI, Materials Science Division, Argonne National Laboratory, GIULIA GALLI, Pritzker School of Molecular Engineering, University of Chicago — Interfaces between water and solid surfaces are key to many technological applications, including electrochemical devices, the fabrication of membranes for water purification and sensors for biomedical devices. Here we consider a bio-compatible material, SiC, of interest for biosensing and electrochemistry applications. We investigated the interaction of water with its hydrophobic and hydrophilic interfaces using first principles molecular dynamics and the Qbox code (http://qboxcode.org/). We report results on band offsets between the solid and the liquid and their dependence on the atomistic structure of the interface, which in turn is related to the hydrophobic or hydrophilic character of the solid termination. In addition, we will discuss the effect of an external applied electric field at the interface, to understand how the interface properties are modified under typical electrode working conditions.

*Part of this work was supported as part of the Advanced Materials for Energy-Water Systems (AMEWS) Center, an Energy Frontier Research Center funded by DOE/BES.

12:51PM G45.00007: Continuum models to handle electrolyte solutions effects in first-principles simulations of materials

OLIVIERO ANDREUSSI (Presenter), Department of Physics, University of North Texas — Continuum models of solvation have played a crucial role in quantum chemistry simulations and are now starting to be popular for the computational characterization of solvated, possibly electrified, interfaces. Recent advances in the field opened the possibility of modeling heterogeneous catalysis and electrochemistry in a first-principles-based framework, where the multiscale nature of the developed approaches provides a significant reduction of the computational burden while retaining a good accuracy. Nonetheless, extending continuum approaches to condensed-matter simulations present non-trivial issues, related to the complexity of the electrostatic problem in charged 2D interfaces and to the open structure of many crystalline substrates. Here we will present some of our recently proposed approaches to overcome these limitations, in particular focusing on a hierarchy of methods to describe the electrochemical diffuse layer. Moreover, handling environment effects through continuum embedding allows us to exploit a rigorous grand canonical approach to study the thermodynamic properties of electrochemical interfaces, thus overcoming some limitations of the computational-hydrogen electrode technique. Applications to noble metal (electro-)catalysis and beyond will be presented.
1:03PM G45.00008: Engineering Trimetallic Core-shell Nanoclusters for CO₂ Electro-reduction at Low Overpotentials  RAFIA AHMAD (Presenter), King Abdullah Univ of Sci & Tech (KAUST) — Storing energy in chemical bonds and finding an electrochemical catalyst to reduce CO₂ to hydrocarbon fuels such as CH₄ would provide an ideal solution for discontinuous renewable energy sources. Commercially used pure copper catalysts are known to possess the best Faradaic yield capacity (up to 50%) for CO₂ conversion to CH₄, however these require large overpotentials to perform this transformation. Using density functional theory (DFT), we tailor TMₓNi₁₃₋ₓ@Cu₄₂ (TM = 3d transition metals; x = 3, 6, and 9) nanoclusters to catalyze CO₂ electro-reduction to CH₄ with lower overpotentials than commercial catalysts. Among these, Sc₅(6)Ni₈(7)@Cu₄₂ possess unprecedented low overpotentials, ~0.17 V below standard potential value (SPV). The given core compositions ensure the optimal position of d-band center of Cu, which is required for better interaction with π orbital of CHO than with CO. This results in better stabilization of CHO, giving exergonic CO reduction. Estimated statistical coverage of CHO exceeds CO by 60% at ambient conditions on Sc₅Ni₈@Cu₄₂, ensuring CO₂ conversion to high end fuel CH₄ without CO poisoning. The energetics of the reaction pathway and the overpotential values are relatively unchanged with the inclusion of implicit aqueous solvent.

1:15PM G45.00009: Adsorption of small gas molecules on a single Pt atom supported by pristine graphene: diffusion Monte Carlo study  JEONGHWAN AHN (Presenter), IUE GYUN HONG, KonKuk Univ, HYEONDEOK SHIN, ANOUAR BENALI, Computational Science Division, Argonne National Laboratory, YONGKYUNG KWON, KonKuk Univ — We have used diffusion Monte Carlo (DMC) method to study adsorption of small gas molecules on a single Pt atom supported by pristine graphene. Firstly, we obtain Pt-graphene binding energy curves as a function of the vertical distance between Pt and graphene for three different adsorption sites (bridge, on-top, hollow), from which the equilibrium binding energies and distances are determined. Our DMC results are compared with DFT results based on several different density functionals, which reveals that PBE and rVV10 results show good agreement with our DMC results for both equilibrium energies and distances. For molecular adsorption on the Pt-graphene complex, we observe significant overestimation in DFT binding energies compared to the DMC ones. In the case of O₂ adsorption, the spin degrees of freedom are considered along with geometries. While DFT predicts the lowest-energy structure of a spin-triplet side-on configuration where the molecular axis of O₂ is parallel to the graphene sheet, DMC finds that the spin-singlet side-on configuration with the molecular axis being slightly tilted toward graphene is the lowest-energy state. The DMC calculations are currently in progress to examine diffusion path of O₂ and catalytic performance of Pt-graphene complexes.
1:27PM G45.00010: Morphological stability of electrodeposition through a viscoelastic coating*  PAUL RUDNICKI (Presenter), XIAN KONG, JIAN QIN, Stanford Univ — Lithium metal anodes, the key component of several emerging lightweight, energy-dense battery chemistries, continue to suffer from serious safety and cycle life concerns due to dendritic lithium growths. A promising approach toward dendrite suppression is to insert a viscoelastic polymeric interphase between the anode and the separator. Good coating layers have been empirically found to exhibit instantaneous elastic response and adaptability to volume change, but no mechanistic understanding was established. We develop a continuum model to study the effects of a polymer coating on the morphological dendritic instability by explicitly incorporating the viscoelastic response and the dielectric permittivity of the polymer. The effects of charging current density and overpotential during cycling are explored, and the coating properties and battery operation conditions for stable, uniform lithium growth and long cycle life are discussed.

Graduate Research Fellowship under Grant No. DGE-1656518, the Assistant Secretary for Energy Efficiency and Renewable Energy, Office of Vehicle Technologies of the U.S. D.O.E. through the Battery500 Consortium, the 3M Non-Tenured Faculty Award, and the Hellman Scholar Award.

1:39PM G45.00011: Field-Aware Interfaces in Continuum Solvation  MATTHEW TRUSCOTT (Presenter), OLIVIERO ANDREUSSI, Univ of North Texas — The continuum embedding approach has seen a rapid influx of interest from the condensed matter community in recent years. We present here a number of additions to the modelling of continuum interfaces that aim to provide an implicit consideration of charged species and compounds with highly polarized regions in an effort to further expand on the capabilities of continuum models, especially in the treatment of electrochemical interfaces. These advances follow recent approaches of using the electric field as an effective proxy for the localized charge surrounding a specific region. This “field-aware” approach is applied to the recently proposed soft-sphere continuum solvation (SSCS) method, wherein the radius of each soft-sphere composing the interface is readjusted as a function of the field flux through its surface, as well as the self-consistent continuum solvation (SCCS) method, whose interface definition is modified by the normal component of the electric field. In both cases, a complex dependence of the interface function on both the electronic and ionic degrees of freedom of the solute is introduced. Analytic derivatives of the new interface are thus implemented during optimization procedures (SCF and geometry optimization).

Session G46 GMAG DMP: Pyrochlores II: Spin Liquids  708 - Oleg Tchernyshyov, Johns Hopkins University - Tag(s): Focus
Dynamics of a pyrochlore quantum spin liquid NaCaNi$_2$F$_7$*

SHU ZHANG (Presenter), Physics, University of California, Los Angeles, HITEME CHANGLANI, Florida State University, KEMP PLUMB, Brown University, OLEG TCHERNYSHYOV, Johns Hopkins University, RODERICH MOESSNER, Max-Planck Institute for the Physics of Complex Systems — The Heisenberg antiferromagnet on a pyrochlore lattice is a well-known model realizing a classical spin-liquid state at low temperatures [1]. Much less is known about the quantum version of this model. The spin-1 pyrochlore material NaCaNi$_2$F$_7$ is well described by a weakly perturbed Heisenberg Hamiltonian [2]. It shows no magnetic order down to extremely low temperatures, making it a prime candidate for a three-dimensional quantum spin liquid. Inelastic neutron scattering has revealed a lack of magnetic Bragg peaks and a broad continuum of excitations incompatible with a conventional magnetically ordered state. We combine analytical theory and numerical approaches to elucidate the nature of this enigmatic spin-liquid state [3]. The three approaches---molecular dynamics simulations, stochastic dynamical theory and linear spin wave theory---reproduce remarkably well the energy and momentum dependence of the experimental inelastic neutron scattering intensity with the exception of the lowest energies. Our study offers the following picture of spin dynamics in this system. This frustrated magnet is slowly moving through a (very large) manifold of degenerate ground states lacking long-range order. This slow motion is driven by medium- and high-energy spin waves with Bose statistics. We discuss two surprising aspects and their implications for quantum spin liquids in general: the complete lack of sharp quasiparticle excitations in momentum space and the success of the linear spin wave theory. Similar conclusions have been reached independently about a $S=3/2$ "pyrochlore" antiferromagnet MgCr$_2$O$_4$ [4].

*Supported by the Institute for Quantum Matter under DOE EFRC grant DE-SC0019331.
11:51AM G46.00002: Magnetic field dependence of magnetic correlations in a pyrochlore Heisenberg antiferromagnet  ALBERTO DE LA TORRE (Presenter), Brown University, JASON W. KRIZAN, Princeton University, GUANGYONG XU, NIST, ROBERT J. CAVA, Princeton University, KEMP PLUMB, Brown University — Recent neutron experiments on the S=1 pyrochlore NaCaNi$_2$F$_7$ [1] revealed a dynamic structure factor exhibiting pinch points and a continuum of high energy magnetic excitations. These signatures point towards a magnetic ground-state which can be described by an almost ideal Heisenberg antiferromagnet on the pyrochlore lattice. Although a highly degenerate ground state its expected at low temperatures, disorder freezes the spin degrees of freedom so that a specific spin configuration is preferred [2]. How disorder induces a frozen spin state in this Coulomb phase [3] remains to be fully understood. We present here a set of neutron scattering measurements in NaCaNi$_2$F$_7$ as a function of external magnetic field. Above a threshold field, $H > 2$ T, a long-range ordered magnetic field polarized phase emerges. I will discuss the magnetic field and temperature evolution of magnetic correlations in NaCaNi$_2$F$_7$ through this polarized phase.

12:03PM G46.00003: Ultrasound Velocity Measurements in Bond-Disordered Pyrochlore Magnet NaCaCo$_2$F$_7$  TADADATAKA WATANABE (Presenter), HIROYA KATO, Nihon Univ - Tokyo, YOSHIKAKI HARA, Nat Inst Tech Ibaraki Col, JASON W. KRIZAN, ROBERT J. CAVA, Princeton Univ — Pyrochlore cobalt fluoride NaCaCo$_2$F$_7$ is a geometrically frustrated magnet, which exhibits spin freezing below $T_f \sim 2.4$ K while the Weiss temperature is $\theta_W \sim -140$ K. The spin-freezing behavior in this compound is considered to be due to the presence of bond randomness which is generated by the random occupation of Na$^+$ and Ca$^{2+}$ ions on the pyrochlore A sites. We perform ultrasound velocity measurements in a single crystal of NaCaCo$_2$F$_7$. Temperature ($T$) dependence of the bulk modulus $C_B = (C_{11} + 2C_{12})/3$ exhibits Curie-type $-1/T$ softening upon cooling below $\sim 20$ K down to $T_f$, which should be a precursor to the lattice distortion at $T_f$. And this softening is suppressed by the application of magnetic field, indicating that the spin freezing is driven by the spin-lattice coupling. For the bond-disordered frustrated NaCaCo$_2$F$_7$, the softening in the breathing elastic mode of $C_B$ above $T_f$ suggests that the spin freezing, or the release of frustration is a result of the enhancement of the bond randomness driven by the spin-lattice coupling.
12:15PM G46.00004: Low energy excitations in Tb$_2$Ti$_2$O$_7$ with [111] magnetic field*  XINSHU ZHANG (Presenter), SEYED KOOHPAYEH, PETER ARMITAGE, Johns Hopkins University — The pyrochlore magnet Tb$_2$Ti$_2$O$_7$ has shown exotic magnetic properties and has been considered to be a quantum spin liquid. Although Tb$_2$Ti$_2$O$_7$ has been studied for decades, low energy experiments with magnetic field along [111] are rare. We perform time-domain terahertz spectroscopy on high quality Tb$_2$Ti$_2$O$_7$ crystal to study the crystal field excitations as a function of magnetic field with very high resolution. The excitations behaves significantly different below and above a critical field, indicating a phase transition around 2.5 T. We also observed the discrepancy between two polarization channels. Our work provides insight into this very intriguing material.

12:27PM G46.00005: THz spectroscopy study of the rare-earth pyrochlore Tb$_2$Ti$_2$O$_7$* KIRILL AMELIN (Presenter), TOOMAS ROOM, URMAS NAGEL, National Institute of Chemical Physics and Biophysics, EVAN CONSTABLE, Institute of Solid State Physics, TU Wien, ZHE WANG, Institute of Physics II, University of Cologne, YANN ALEXANIAN, JULIEN ROBERT, RAFIK BALLOU, SOPHIE DEBRION, Institut Néel, CNRS — Tb$_2$Ti$_2$O$_7$ is unique rare-earth pyrochlore in that it does not exhibit theoretically predicted long-range magnetic order down to the lowest measured temperatures below 100 mK. Instead, a fluctuating spin-liquid state with short-range correlations persists, while strong spin-lattice coupling occurs. As a manifestation of this coupling, the two lowest crystal electric field (CEF) level doublets separated by approximately 1.5 meV = 0.42 THz have been shown to couple to a transverse acoustic phonon. Such a vibronic process is accompanied by hybrid magnetoelastic excitations, which have been previously detected by neutron scattering and THz spectroscopy.

We measured absorption of THz radiation in a single crystal at the temperatures 3 K and 60 K combined with magnetic fields up to $B = 15$ T applied along the local [111] axis. The $B$ dependence of the crystal field excitations gives us the opportunity to accurately describe the CEF spectrum including the vibronic process, and to see how it is transformed by a static magnetic field.

12:39PM G46.00006: Probing Multipolar Quantum Spin Liquids in non-Kramers Pyrochlore Materials with Magnetostriction.* ADARSH PATRI, University of Toronto, MASASHI HOSOI (Presenter), University of Tokyo, SUNGBIN LEE, Korea Advanced Institute of Science and Technology, YONG-BAEK KIM, University of Toronto — Quantum spin liquids (QSLs) and Multipolar ordered states (MPOs) both share the property of being notoriously difficult to detect with conventional probes. Recently, lattice-based techniques are proposed as novel probes to detect MPOs. Motivated by this success, we investigate the possibility of detecting QSL when it arises from interacting multipolar moments. In this talk, we theoretically propose that spin-lattice coupling can be used as a powerful tool to probe such multipolar QSL phases.

12:51PM G46.00007: Half-moon quantum spin liquid in a spin-1/2 J₁-J₂-J₃a Heisenberg antiferromagnet on the pyrochlore lattice PRATYAY GHOSH, Paul Scherrer Institut, TOBIAS MÜLLER, University of Wuerzburg, JOHANNES REUTHER, Physics Department, Freie Universitaet Berlin, RONNY THOMALE, University of Wuerzburg, MICHEL J P GINGRAS, University of Waterloo, YASIR IQBAL (Presenter), Indian Institute of Technology Madras — We investigate the quantum Heisenberg model on the pyrochlore lattice for spin-1/2 in the presence of antiferromagnetic nearest-neighbor J₁, second nearest-neighbor J₂, and third nearest-neighbor J₃a exchange interactions. By employing the pseudofermion functional renormalization group method, we find, that the quantum Coulomb spin liquid of the J₁ only model is robust along the line J=J₂=J₃a up till J/J₁~0.22, thus extending its classical region of stability. Similarly, for J/J₁>0.22, we find an absence of long-range magnetic order down to T=J₁/100, however, the bowtie features now give way to half-moons as seen in the static spin susceptibility profile, thus pointing to the realization of a ‘half-moon’ quantum spin liquid. At the point J/J₁=1/2, which features a sub-extensively degenerate classical ground-state manifold, we show that quantum fluctuations fail to break this degeneracy stabilizing a quantum spin liquid. In stark contrast to this finding, in the corresponding classical model, thermal fluctuations are known to select a collinear antiferromagnetically ordered state via the order-by-disorder mechanism. Hence, we present a rare scenario wherein thermal and quantum fluctuations act differently.
Experimental signatures of a three-dimensional quantum spin liquid in effective spin-1/2 Ce$_2$Zr$_2$O$_7$ pyrochlore* [Invited]  BIN GAO (Presenter), TONG CHEN, DAVID W TAM, CHIEN-LUNG HUANG, Rice Univ, KALYAN SASMAL, University of California, San Diego, DEVASHIBHAI ADROJA, ISIS Facility, STFC Rutherford-Appleton Laboratory, FENG YE, HUIBO CAO, GABRIELE SALA, MATTHEW STONE, Neutron Scattering Division, Oak Ridge National Laboratory, CHRISTOPHER BAINES, JOEL BARKER, Laboratory for Muon-Spin Spectroscopy, Paul Scherrer Institut, HAOKU HU, Rice Univ, JAE-HO CHUNG, Department of Physics, Korea University, XUANGHAN XU, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, MANIVANNAN NALLAIYAN, STEFANO SPAGNA, Quantum Design Inc., M BRIAN MAPLE, University of California, San Diego, ANDRIY NEVIDOMSKYY, EMILIA MOROSAN, Rice Univ, GANG CHEN, Department of Physics and Center of Theoretical and Computational Physics, The University of Hong Kong, PENGCHENG DAI, Rice Univ — A quantum spin liquid (QSL) is an exotic state of matter where unpaired electrons’ spins, although being entangled, do not show magnetic order even at the zero-temperature. Because such a state may be important to the microscopic origin of high-transition temperature superconductivity and useful for quantum computation, the experimental realization of QSL is a long-sought goal in condensed matter physics. Although neutron scattering experiments on the two-dimensional QSL candidates ZnCu$_3$(OD)$_6$Cl$_2$ and YbMgGaO$_4$ have found evidence for the hallmark of a QSL at very low temperature - a continuum of magnetic excitations, the presence of site disorder complicates the interpretation of the data. Recently, the three-dimensional (3D) Ce$^{3+}$ pyrochlore lattice Ce$_2$Sn$_2$O$_7$ has been suggested as a clean, effective spin-1/2 QSL candidate, but the evidence of a spin excitation continuum is missing due to the lack of single crystals. Here we use alternating current magnetic susceptibility, thermodynamic, muon spin relaxation ($\mu$SR), and neutron scattering experiments on single crystals of Ce$_2$Zr$_2$O$_7$, a compound isostructural to Ce$_2$Sn$_2$O$_7$, to demonstrate the absence of magnetic ordering/spin-glass down to 20 mK and the presence of a spin excitation continuum at 35 mK. With no evidence of oxygen deficiency and chemical disorder seen by diffuse scattering measurements and neutron diffraction, Ce$_2$Zr$_2$O$_7$ may be a 3D pyrochlore lattice QSL material with minimum magnetic and nonmagnetic chemical disorder.

Interplay between magnetic exchange, multipolar interactions and virtual crystal field fluctuations in non-Kramers pyrochlore magnets

WEN JIN (Presenter), MICHEL J P GINGRAS, University of Waterloo, HALLAS ALANNAH, University of British Columbia, JONATHAN GAUDET, Johns Hopkins University, BRUCE D. GAULIN, McMaster University — It has been shown that multipolar degrees of freedom can play a vital role in causing exotic phases in pyrochlore magnets, such as octupoles in Kramers Nd$^{3+}$ or Ce$^{3+}$ ions and quadrupoles in non-Kramers Pr$^{3+}$ and Tb$^{3+}$ ions. Terbium-based pyrochlores are peculiar for hosting virtual crystal field excitation (VCFE) due to the small energy separation between the two low-lying crystal electric field doublets. Here we consider a two-doublets system with magnetic bilinear exchange and electric quadrupole-quadrupole interaction. Via a mean field approach, we show that the proposed model exhibits complex dipolar and quadrupolar phases. Different dipolar order parameters coexist due to VCFE, which also leads to a “parasitic” ferroquadrupolar order accompanying the dominant antiferroquadrupolar order. We find for a set of model parameters locating the system near the dipolar/quadrupolar phase boundary that, upon cooling, such system may undergo a two-step thermal transition into the ultimate low-temperature dipolar phase with an intermediated quadrupolar ordered state. We also propose a range of acceptable parameters for the Tb$_2$Ge$_2$O$_7$ pyrochlore that allows us to reproduce some of the main inelastic neutron scattering features.
1:51PM G46.00010: Crystal Field Excitations in Raman Spectra of Pr-based Pyrochlores*

YUANYUAN XU (Presenter), Department of Physics and Astronomy, Johns Hopkins University, TAKUMI OHTSUKI, The Institute for Solid State Physics, The University of Tokyo, HUIYUAN MAN, Department of Physics, Stanford University, NAN TANG, The Institute for Solid State Physics, The University of Tokyo, SANTU BAIDYA, Department of Physics and Astronomy, Rutgers University, HONGBIN ZHANG, Institut für Materialwissenschaft, Technische Universität Darmstadt, SATORU NAKATSUJI, The Institute for Solid State Physics, The University of Tokyo, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University, NATALIA DRICHKO, Department of Physics and Astronomy, Johns Hopkins University — Interplay of strong electron correlations and spin-orbit coupling leads to exotic magnetic phases in rare earth pyrochlores. Here we present a study of Pr$_2$Ir$_2$O$_7$ and Pr$_2$Zr$_2$O$_7$, which show magnetic interactions but no ordering down to low temperatures [1-3]. We performed low temperature Raman scattering spectroscopy study of Pr$_2$Ir$_2$O$_7$ and Pr$_2$Zr$_2$O$_7$ single crystals to probe crystal field excitations and phonons. A comparison of crystal field excitations in these two materials reveals a splitting in the Pr$^{3+}$ crystal field doublet at 57 meV in Pr$_2$Zr$_2$O$_7$, possibly originating from the magneto-elastic coupling induced vibronic state. An anomalous broadening of this crystal field excitation is observed in Pr$_2$Ir$_2$O$_7$. A comparison of phonon spectrum to the density functional theory calculations demonstrates an anomalous broadening/splitting of the $E_g$ phonon mode corresponding to the Ir-O-Ir (Zr-O-Zr) bending. We discuss relevance of our findings to magnetic properties of these materials.

*Supported by the Institute for Quantum Matter under DOE EFRC grant DE-SC0019331

2:03PM G46.00011: Probing Emergent Excitations in Pr$_2$Hf$_2$O$_7$ with Thermal Conductivity

JENNIFER REID (Presenter), SHAUN FROUDE-POWERS, University of Waterloo, ALEXANDROS SAMARTZIS, BELLA A C I LAKE, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, ROBERT HILL, University of Waterloo — Pr$_2$Hf$_2$O$_7$ (PHO) is a quantum spin ice candidate with a non-Kramers doublet ground state that displays evidence of dynamic spin ice behaviour [1][2]. We report thermal conductivity measurements of single crystal samples of PHO as a function of temperature between 50 mK and 50 K and magnetic field up to 12 T. A combination of high magnetic field measurements and measurements of different sized samples are used to identify the lattice contribution. We interpret our results considering current theoretical predictions for exotic excitations in quantum spin liquids, such as emergent photons, magnetic monopoles and visons [3].

Tuesday, March 3, 2020 11:15 AM - 2:15 PM
Non-magnetic Origin of Spin Hall Magnetoresistance in Pt films and Epitaxial NiO/Pt bilayers  

ALEXANDRA CHURIKOVA (Presenter), DAVID BONO, BRIAN NELTNER, Massachusetts Institute of Technology MIT, LARRY SCIPIONI, ADAM SHEPARD, PVD Products, Inc., ANGELA WITTMANN, FELIX BUETTNER, Massachusetts Institute of Technology MIT, TY NEWHOUSE-ILLIGE, JAMES GREER, PVD Products, Inc., GEOFFREY BEACH, Massachusetts Institute of Technology MIT  

— Recently, electrical control of the magnetic order in antiferromagnetic insulators (AFIs) with a Pt overlayer as a spin current source has been a subject of great interest [1-4], as it allows for ultra-low power control of the magnetic order. However, the detection and nature of purely AFI magnetoresistive switching remains elusive [5-6]. Here, we show that the Pt signal has a strong bias due to the device-dependent current distribution and subsequent electromigration. We determine the effect of current density and magnetic layer thickness on the spin Hall magnetoresistance magnitude and signal shape of both Pt films and NiO(111)/Pt bilayers grown on sapphire substrate. The signal in both materials has a strong temperature dependence, and an exponential dependence on current, indicating the presence of thermally activated mechanisms. We suggest that more sophisticated techniques that directly probe the magnetic order are required to infer information about the AF magnetic state in such systems.

11:27AM G47.00002: Anisotropic Magnetoresistance and Nontrivial Spin Magnetoresistance in Pt/α-Fe₂O₃ Bilayers*  
SISHENG YU (Presenter), YANG CHENG, ADAM S AHMED, MENG LIN ZHU, JIN WOO HWANG, FENG YUAN YANG, Ohio State Univ - Columbus — Recently antiferromagnetic insulators (AFM) play an import role in spintronic research including the spin superfluid and long distance spin transport. However, magnetic proximity effect (MPE) has not been conclusively observed in antiferromagnet based systems. In this work, we observed anomalous Hall effect and anisotropic magnetoresistance in angular dependent magnetoresistance (ADMR) measurements in Pt on antiferromagnetic (AF) α-Fe₂O₃ (0001) epitaxial thin films at 10 K, which provide evidence for the MPE[1]. The Néel order of α-Fe₂O₃ and the induced magnetization in Pt show a unique ADMR compared with all other FM and AF systems. A macrospin response model is established and can explain the AF spin configuration and all main ADMR features in the Pt/α-Fe₂O₃ bilayers.

11:39AM G47.00003: Magnetic anisotropy in a single crystal antiferromagnetic thin film*  
SAIMA SIDDIQUI (Presenter), University of Illinois at Urbana-Champaign, JOHN PEARSON, Argonne National Laboratory, AXEL HOFFMANN, University of Illinois at Urbana-Champaign — Antiferromagnetic (AF) materials promise to show magnetization dynamics, including switching, at ultra-high frequency and thus are of immense interest for next generation memory and logic applications. Besides, spin waves in AF insulators propagate very efficiently. However, electrically reading the states of the AF materials is not easy. Recently, spin Hall magnetoresistance (SMR) has been identified as one of the promising ways to access the surface states of the AF insulators. In this work, we deposit α-Fe₂O₃ (200 nm)/Pt (6 nm) on (11-20) Al₂O₃. We measure SMR of Pt Hall bar on Fe₂O₃. Below Morin transition temperature, we observe positive and negative magnetoresistance in the Pt/Fe₂O₃ bilayers depending on the direction of the electrical currents at the spin flop transition. This identifies that SMR can clearly determine the anisotropy of thin film AF insulators. We will show the detail study of the dependence of magnetoresistance on angular fields at different temperatures. Our study reveals important physical phenomena in AF Fe₂O₃ thin film.

11:51AM G47.00004: Néel vector switching in enhanced-\(T_N\) magnetoelectric thin films* 
ATHER MAHMOOD (Presenter), WILL ECHTENKAMP, JUNLEI WANG, CHRISTIAN BINEK, University of Nebraska - Lincoln — Controlling magnetism by electrical means is a key challenge in the field of spintronics and essential for energy efficient devices in computing. Voltage-controlled switching of magnetization is manifested through boundary magnetization in \(\text{Cr}_2\text{O}_3\) and promises non-volatile spintronic memory and logic devices. In pure \(\text{Cr}_2\text{O}_3\), switching of the state variable takes place through magnetoelectric reversal of the Néel vector but the operation is limited to \(T< 307\) K. In contrast, in B-doped \(\text{Cr}_2\text{O}_3\), toggling of antiferromagnetic states is demonstrated in zero magnetic field between 300 and 400K. Various mechanisms including concentration dependent \(T_N\)-enhancement, voltage-controlled anisotropy, spin-canting, and a Néel spin orbit torque are simultaneously activated. Our results demonstrate that B-doping turns magnetoelectric \(\text{Cr}_2\text{O}_3\) into a high-\(T_N\) multi-functional material with electrically switchable Néel vector enabling CMOS compatible ultra-low power antiferromagnetic spintronics which operates in zero magnetic field.

*This work was supported in part by the MURI program, by nCORE, a subsidiary of the SRC, by AMML and NSF, and by MRSEC. The research was performed in part in the Nebraska Nanoscale Facility, and NCMN which are supported by the NSF and the Nebraska Research Initiative.

12:03PM G47.00005: Voltage Controlled Anisotropy in Boron-doped \(\text{Cr}_2\text{O}_3\) thin films*  
WILL ECHTENKAMP (Presenter), Ather Mahood, Christian Binek, University of Nebraska - Lincoln — Voltage controlled magnetization is a promising route for next-generation low-energy magnetic recording and logic devices. Utilizing magnetoelectric chromia (\(\text{Cr}_2\text{O}_3\)) based heterostructures, electric control of ferromagnetic exchange bias has been achieved up to the bulk Néel temperature of 307 K. Recently, it has been shown the Néel temperature of chromia can be increased to 400 K by boron doping. Moreover, boron doping could also introduce spin canting and enhance voltage controlled anisotropy which has been predicted in pure chromia, transforming B-doped chromia into a high-\(T_N\) multi-functional material. Here the spin flop transition of chromia is investigated and inferences about the crystal anisotropy are drawn. Utilizing low-temperature spin-flop magnetic measurements in B-doped chromia thin films, voltage controlled anisotropy is investigated for the first time in these films, with significant implications for future spintronic devices.

*This work was supported in part by the MURI program, by nCORE, a subsidiary of the SRC, by AMML and NSF, and by MRSEC. The research was performed in part in the Nebraska Nanoscale Facility, and NCMN which are supported by the NSF and the Nebraska Research Initiative.
12:15PM G47.00006: Antiferromagnetic Domain Dynamics in Nickelate Heterostructures
SANGJAE LEE (Presenter), JUAN JIANG, Yale University, GILBERTO F L FABBRIS, CLAUDIO MAZZOLI, Brookhaven National Laboratory, ANKIT DISA, Yale University, MARK DEAN, Brookhaven National Laboratory, FREDERICK J WALKER, CHARLES H AHN, Yale University — Understanding the energetics of the antiferromagnetic (AF) domains and the timescale of their fluctuations in a magnetic material are important for its application in spin-based electronics. NdNiO₃ (NNO) undergoes an AF transition at ~150K, and thus it serves as an oxide platform to study and engineer its AF ground state. We investigate how dimensional confinement leads to phase fluctuations in atomically layered (NdNiO₃)ₘ/(NdAlO₃)ₙ heterostructures through x-ray photon correlation spectroscopy (XPCS). The speckle patterns arising from coherent x-ray scattering provide the information on long- and short- ranged correlations for different heterostructures with varying thickness of nickelate layers, m, and aluminate layers, n. We find that the dynamics of the AF domain boundaries are dramatically enhanced as the dimensionality of the NNO layers are reduced, approaching the 2D limit. The dynamics of AF domain fluctuations in the heterostructure can be further tailored by tuning the interlayer coupling of nickelate layers. Our study demonstrates a path to characterize any long-range orders in quantum materials under dimensional effect and enables us to control AF domain configurations in oxide heterostructures.
12:27PM G47.00007: Spin transport in antiferromagnetic insulators: progress and challenges [Invited]  DAZHI HOU (Presenter), Hefei National Laboratory for Physical Sciences at the Microscale (HFNL), University of Science and Technology, China, ZHIYONG QIU, Dalian University of Technology, Dalian, China, JOSEPH BARKER, School of Physics and Astronomy, University of Leeds, KEI YAMAMOTO, Japan Atomic Energy Agency, OLENA GOMONAY, Institute of physics, Johannes Gutenberg Universität Mainz, Mainz, Germany, EIJI SAITOH, University of Tokyo — Spin transport is the key process for the operation of spin-based devices, which has been the focus of the spintronics research in the last two decades. Conductive materials such as semiconductors and metals, in which the spin transport relies on electron diffusion, were employed as the channels for spin transport in most studies. Due to the absence of conduction electron, insulators were excluded from the candidates for spin current channel before 2010. However, since the demonstration of the spin transmission through ferromagnetic insulator, it was realized that insulators with magnetic ordering can also serve as channels for spin transport[1]. In this talk I would like to introduce our recent progress of spin transport in antiferromagnetic insulators, e.g., the observations of temperature dependence of spin transmission, and spin current switching[2,3]. I would like to discuss the challenges for developing the functionality of antiferromagnetic insulator as well[4].

1:03PM G47.00008: Spin Transport in Multiferroic BiFeO$_3$ thin films*  HONGRUI ZHANG (Presenter), XIAOXI HUANG, YEN-LIN HUANG, RAMAMOORTHY RAMESH, Department of Materials Science and Engineering, University of California, Berkeley — Creation, detection, manipulation of spin current are the core issues in the spintronics field. In general, spin current can be manipulated by tuning charge current. BiFeO$_3$ is a multiferroic material, which has a strong magneto-electric coupling. We study spin-current transmission in La-doped BiFeO$_3$ (LBFO) thin films by using a trilayer device that sandwiches a LBFO thin film between a magnetic CoFe and a strong spin orbit coupling SrRuO$_3$ layer. Spin current transmission in LBFO thin films can be controlled by the electric field and La-doping concentration through changing antiferromagnetic spin orientation. The control of pure spin current by multiferroic materials may provide a new route towards next-generation electronics.

*This work is supported by an ARO-MURI
1:15PM G47.00009: Unleashing antiferromagnetic fluctuations for charge and spin responses of pseudo-spin-half square-lattice  LIN HAO (Presenter), JUNYI YANG, HAN ZHANG, University of Tennessee, Knoxville, DEREK MEYERS, Brookhaven National Laboratory, HIDEAMARU SUWA, ZHENTAO WANG, University of Tennessee, Knoxville, MARK DEAN, Brookhaven National Laboratory, CRISTIAN BATISTA, JIAN LIU, University of Tennessee, Knoxville — While manipulation of antiferromagnetic (AFM) order arises to the forefront of spintronics, it is a long-standing fundamental problem lying at the heart of correlated electron physics. Here we will present a series of exciting findings in pseudo-spin-half square-lattice systems, which are implemented as artificial layered iridates [(SrIrO$_3$)$_1$/SrTiO$_3$]$_m$ to engage with a staggered magnetic field effect (STMF) due to strong spin-orbit interaction. By tuning the SrTiO$_3$ spacer, the AFM structure of the Mott insulating state can be engineered [Phys. Rev. Lett. 119, 027204 (2017)]. With $m = 1$, the STMF leads to an intriguing positive anomalous magnetoresistance that probes the AFM susceptibility, because of the strong interplay between charge and longitudinal spin fluctuations [Nat. Commun. Accepted (2019)]. Upon driving the AFM structure to the two-dimensional limit at $m = 2$, while the ordering temperature is significantly reduced by strong critical fluctuations, the STMF allows an external field of only a thousandth of the superexchange interaction to greatly suppress the AFM fluctuations and enable a giant response of the AFM order [Nat. Phys. 14, 806 (2018)].

1:27PM G47.00010: Intrinsic Exchange Bias in Epitaxial CoFe2O4 thin film* DETIAN YANG (Presenter), XIAOSHAN XU, YU YUN, Physics & Astronomy, University of Nebraska-Lincoln — Exchange bias (EB), traditionally known as an interface phenomenon between ferro- or ferrimagnetic (FM) materials and antiferromagnetic (AFM) materials, has been successfully applied in magnetic storage and spintronic devices. Recently, surprising “intrinsic” EB (IEB) effects without a nominal AFM layer have drawn much attention. To ascertain the mechanism of IEB, we grew CoFe2O4 thin films epitaxially on sapphire (0001) substrates by pulsed laser deposition and studied its magnetometry by superconducting quantum interference device. In this single film, magnetization loops indicate the coexistence of a soft and a hard FM component, while the observed EB effect ---their clear shifts from the origin, suggest the existence of another AFM component. Analyses based on Preisach model demonstrate that only the hard FM component contributes to the EB. Thickness and temperature dependent EB and coercivity signatures are also extracted from these triple-component hysteresis loops. Our experiment suggests a potential application of adjustable EB and provide new platforms to study the elusive mechanism of intrinsic EB.

1:39PM G47.00011: Fabrication of GeNi$_2$O$_4$, GeCu$_2$O$_4$, and MgCr$_2$O$_4$ Epitaxial Thin Films*
FANGDI WEN (Presenter), DENIS VASIUKOV, MIKHAIL KAREEV, XIAORAN LIU, LIANG WU, Rutgers University, New Brunswick, PADRAIC SHAFER, ELKE ARENHOLTZ, Lawrence Berkeley National Laboratory, Advanced Light Source, JAK CHAKHALIAN, Rutgers University, New Brunswick — In the AB$_2$O$_4$ spinel system with B site magnetic, a rich variety of magnetic and orbital frustration has been observed. Highlighted phenomena like spin-liquid phase and field-induced novel phase transitions were seen in these single-crystal systems extensively. Here we report on the first growth of the (001)-oriented GeNi$_2$O$_4$, (001)-oriented GeCu$_2$O$_4$ and (111)-oriented MgCr$_2$O$_4$. All fabricated films were characterized by X-ray diffraction and X-ray photoelectron spectroscopies confirming both crystalline epitaxy and chemical stoichiometry. Synchrotron-based X-ray absorption spectroscopies were also carried out to prove the correct electronic state. The availability of single-crystalline thin films can pave the road to understand the magnetic ordering of differently-oriented spinels in an ultra-thin limit.

*This work was supported by the Gordon and Betty Moore Foundation's EPIQS Initiative through Grant No. GBMF4534, and by the Department of Energy under Grant No. DESC0012375. 1:51PM G47.00012: Designing complex exchange interaction pathways in spinel films using entropy stabilization*
THOMAS ZAC WARD (Presenter), ALESSANDRO MAZZA, Oak Ridge National Laboratory, BRIANNA MUSICO, University of Tennessee, ELIZABETH SKOROPATA, YOGESH SHARMA, WENRUI ZHANG, Oak Ridge National Laboratory — Magnetic behaviors in AB$_2$O$_4$ spinels are dictated by the magnetic exchange interactions within and between the tetrahedral and octahedral sublattices. Functionality is then tied directly to the distribution and type of cations present within the unit cell. We will present our recent work developing entropic stabilization to synthesize single-crystal high entropy spinel oxide films of the AB$_2$O$_4$ type, where the cation sites are populated by 5 or more elements. We will describe how cation selection can be used to modify the type and strength of exchange interactions present in the crystal lattice. Lab-scale magnetic and structural characterization combined with beamline-based x-ray spectroscopy and neutron diffraction demonstrate the presence of highly tunable and varied magnetic responses; including: room temperature ferrimagnetic insulating states, surface-stabilized spin textures, tunable compensation points, and extraordinarily high strain-induced magnetic anisotropy.

*This work was supported by the Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.
2:03PM G47.00013: Tunable electronic and magnetic properties in Eu$_{1-x}$La$_x$TiO$_3$ (0< x <1) 
HYUNGKI SHIN (Presenter), Department of Physics, University of British Columbia, BRUCE DAVIDSON, FENGMIAO LI, CHONG LIU, Quantum material institute, University of British Columbia, RONNY SUTARTO, Canadian Light Source, KE ZOU, Department of Physics, University of British Columbia — We explore the magnetic transitions and electronic structures of strained Eu$_{1-x}$La$_x$TiO$_3$ (0<x<1) grown by oxide molecular beam epitaxy (MBE). In bulk, undoped EuTiO$_3$ (Ti$^{4+}$) is insulating and antiferromagnetic with a Néel temperature of ~ 5.5 K, while LaTiO$_3$ (Ti$^{3+}$) is a Mott insulator with a Néel temperature of ~ 160K. Previous experiments of doping EuTiO$_3$ or LaTiO$_3$ thin films show novel emergent states, such as ferromagnetism, skyrmions, and metal-insulator transition. We show the studies of high-quality thin films of Eu$_{1-x}$La$_x$TiO$_3$ from x = 0 to x = 1. With a different ratio of Eu$^{2+}$/La$^{3+}$, we observe a series of transitions in the films. We will complete the phase diagram of this system.

Tuesday, March 3, 2020 11:15 AM - 2:15 PM

Session G48 DCMP: Superconductivity in Low Dimensional Systems II

11:15AM G48.00001: Dimensionality of the Zeeman energy in conductors* RICHARD KLEMM (Presenter), AIYING ZHAO, Physics, Univ of Central Florida, QIANG GU, Physics, University of Science and Technology Beijing, TIMOTHY HAUGAN, Wright-Patterson Air Force Base, US Air Force Research Laboratory — The Dirac equation is extended for a relativistic electron or hole in an orthorhombically-anisotropic conduction band with effective masses $m_j$ for j=1,2,3 with geometric mean $m_g=(m_1m_2m_3)^{1/3}$. Its covariance is established with general proper and improper Lorentz transformations. The non-relativistic Hamiltonian is evaluated to order $1/(mc^2)^4$, where $mc^2$ is it's Einstein rest energy. For the magnetic induction $B$ in the crystallographic direction $\hat{e}_j$, the Zeeman $g$ factor is $2m(m_j/m_g^3)^{1/2}$. While propagating in a monolayer two-dimensional conduction band, $g$ is much less than 2 for $B$ parallel to the monolayer, as observed recently in superconducting monolayer NbSe$_2$, $B_{c2,||}$ of which appears to violate the `"Pauli limit" by a order of magnitude. In one-dimensional chain conductors of atomic thickness, $g$ is small for all $B$ directions while the particle is in its conduction band. The precise form for the quantum spin Hall energy is also found for a particle in a two-dimensional metal.

Controlling the charge dispersion of a nearly-open superconducting island

ARNO BARGERBOS (Presenter), WILLEMIJN UILHOORN, QuTech, Delft University of Technology, BERNARD VAN HECK, CHUNG-KAI YANG, Quantum Lab Delft, Microsoft, PETER KROGSTRUP, Quantum Materials Lab Copenhagen, Microsoft, LEO P KOUWENHOVEN, GIJS DE LANGE, ANGELA KOU, Quantum Lab Delft, Microsoft — Isolation from the environment determines the extent to which charge is confined on an island, which manifests experimentally through Coulomb oscillations such as charge dispersion. In superconducting circuits, the link to the environment has typically been formed from tunnel junctions. If instead a transparent ballistic junction forms the link between the superconducting island and the environment, Coulomb oscillations are predicted to suppress far more rapidly than for tunnel junctions due to imaginary-time Landau-Zener tunneling. Here we investigate the charge dispersion of a nanowire transmon hosting a quantum dot in the junction. We observe rapid suppression of the charge dispersion consistent with the scaling law resulting from diabatic transitions between Andreev bound states. We also observe greatly improved qubit coherence times at the point of highest charge dispersion suppression. Our observations further our fundamental understanding of charging effects in superconductors and suggests novel approaches for building charge-insensitive qubits.

This work has been supported by funding from the Dutch Research Council (NWO) and the Microsoft Quantum initiative.

Calorimetric Observation of Magnetic-Field-Induced High-Field FFLO Superconducting Phase in λ-(BETS)$_2$GaCl$_4$

NATHANAEL FORTUNE (Presenter), Physics, Smith College, ANDREAS RYDH, Physics, Stockholm University, JOYCE ELLEN PALMER-FORTUNE, Physics, Smith College, CHARLES C AGOSTA, Physics, Clark University, AKIKO KOBAYASHI, Chemistry, Nihon University — When an external magnetic field is applied parallel to the conducting layers in quasi-2D organic superconductors, a phase transition to a new, high-field, superconducting state with a spatially modulated superconducting order parameter can occur at the Clogston-Chandrasekhar paramagnetic limit $H_p$, as first predicted by Fulde, Ferrell, Larkin, and Ovchinnikov (FFLO). Candidate FFLO phases have been identified through NMR, RF penetration depth, magnetic torque, and transport measurements in a number of organic superconductors; in the case of the archetypal 2D organic superconductor κ-(BEDT-TTF)$_2$Cu(NCS)$_2$, corroborating evidence has been provided by the calorimetric observation of a first order phase transition at $H_p$ into a new high-field, higher-entropy superconducting phase. This evidence has been lacking, however, in other candidate FFLO systems. We report here low-temperature specific heat measurements in a second expected FFLO organic superconductor: λ-(BETS)$_2$GaCl$_4$. For field-angles within 0.5° of plane-parallel, we observe an enhancement of the upper critical field superconducting phase boundary $H_{c2}(T)$, a calorimetric signature of pancake vortex formation with decreasing field at $H_p$, and a field-induced phase transition between the upper and lower superconducting states.
11:51AM G48.00004: Anomalous Metallic Phase in Tunable Destructive Superconductors*
SAULIUS VAITIEKENAS (Presenter), PETER KROGSTRUP, CHARLES MARCUS, Center for Quantum Devices and Microsoft Quantum Lab--Copenhagen, Niels Bohr Institute, University of Copenhagen — The Little-Parks effect---a flux-dependent modulation of the transition temperature in multiply connected superconductors---results from the quantization of fluxoid through holes in superconductors. In hollow superconducting cylinders with diameter smaller than the superconducting coherence length, flux-induced supercurrents can give rise to the destructive Little-Parks effect, characterized by repeated reentrant quantum phase transitions between superconducting and metallic phases. Here, we use axial and transverse magnetic fields to control the crossover between the conventional and destructive Little-Parks regimes in nanowires with an epitaxial Al shell fully surrounding InAs core. The observed dependence on flux, transverse field, temperature, and current bias is in excellent agreement with theory. Near the crossover between the conventional and destructive regimes, an anomalous metal phase is found. The anomalous metallic phase is characterized by a field-controllable, temperature-independent resistivity between adjacent superconducting lobes.

12:03PM G48.00005: Study of 2D superconductivity at oxide interfaces by microwave resonators  YILDIZ SAGLAM (Presenter), EDOUARD LESNE, DANIEL BOTHNER, FELIX SCHMIDT, Delft University of Technology, MARC GABAY, Paris-Saclay University, ANDREA CAVIGLIA, GARY STEELE, Delft University of Technology — The emergent two-dimensional electron system (2DES) formed at the interface between LaAlO3 (LAO) and SrTiO3 (STO) insulating oxides has been a subject of great interest in condensed matter physics during the last decade. Recently, (111)-oriented LAO/STO interfaces have been shown to exhibit an electronic correlation driven reconstruction of its band structure and a two-dimensional superconducting (SC) ground state, both tunable by electrostatic field-effect. Superconducting coplanar waveguide (SCPW) resonators are tools of exquisite sensitivity for probing low energy excitations in quantum materials, due to their intrinsic low ohmic losses and high-quality factors, highly relevant to quantum technology platforms. Here, in order to study the superconducting state at the LAO/STO(111) interface, we designed embedded SCPW resonators whose microwave resonance frequency can be tuned by electrostatic gating, manifesting a change of the 2DES’ superfluid density through a large change of its kinetic inductance. This allows us to map the SC phase diagram in a detection scheme that goes beyond traditional resistive measurements. Our work highlights the potential of such an approach to the fundamental study of superconductivity in complex materials.
12:15PM G48.00006: Ising superconductors: the interplay of magnetic field, triplet channels and disorder*  
DAVID MÖCKLI (Presenter), MAXIM KHODAS, The Racah Institute of Physics, The Hebrew University of Jerusalem — We study the superconducting instability in disordered non-centrosymmetric monolayers with intrinsic Ising spin-orbit coupling (SOC) subjected to an in-plane Zeeman magnetic field. The pairing interaction contains the channels allowed by crystal symmetry, such that in general, the pairing state is a mixture of singlet and triplet Cooper pairs. The joint action of SOC and Zeeman field selects a specific in-plane \( \mathbf{d} \)-vector triplet component to couple with the singlets, which gains robustness against disorder through the coupling. The out-of-plane \( \mathbf{d} \)-vector component, that in the clean case is immune to both the Zeeman field and SOC is obliterated by a small impurity scattering rate. We formulate the quasi-classical theory of Ising superconductors and solve the linearized Eilenberger equations to obtain the pair-breaking equations that determine the Zeeman field - temperature dependence of the continuous superconducting transition. Our discussion emphasizes how the Zeeman field, SOC and disorder affect the different superconducting order parameters, and we show how the spin-fields inevitably induce odd-frequency pairing correlations.

GAURAV CHAUDHARY (Presenter), ZHIQIANG WANG, KATHRYN LEVIN, University of Chicago — In this talk we discuss the signatures of the pseudogap effects seen in transport studies of superconducting magic angle twisted bilayer graphene (MATBG). They should be viewed as rather natural; quite generally pseudogap phenomena are widely observed in very thin superconducting films of conventional materials such as Pb and TiN, high \( T_c \) cuprate superconductors and in interfacial superconductors. The pseudogap regime is characterized by two distinct temperature scales corresponding to the onset of phase coherence, i.e. \( T_{BKT} \) and the onset of pairing, i.e. \( T^* \). Here we develop the pairing fluctuation theory of the Berezinskii-Kosterlitz-Thouless (BKT) transition for the MATBG, demonstrating how pseudogap effects are enhanced in two dimensional superconductors. Moreover, they do not require anomalously strong attractive pairing mechanisms as proposed for the 3D cuprates. Using our theory along with the transport estimates for the pairing onset temperature \( T^* \), we quantify the expected strength of the pairing and fluctuations for the MATBG superconductors. Finally, we propose new tunneling based experiments from one two dimensional system to another, which can further probe the pseudogap phenomena.
12:39PM G48.00008: Quantum transport of atomically thin $1T_d$-MoTe$_2$  XIRUI WANG (Presenter), KENJI YASUDA, Massachusetts Institute of Technology MIT, DANIEL A RHODES, Columbia University, TAKEHITO SUZUKI, Massachusetts Institute of Technology MIT, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, JOSEPH G CHECKELSKY, Massachusetts Institute of Technology MIT, JAMES C HONE, Columbia University, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology MIT — There has been growing interest in the study of crystalline 2D superconductors, especially those with low carrier densities with gate tunability. Recently, it is reported that monolayer $1T_d$-MoTe$_2$ exhibits superconductivity with transition temperature of 8 K [1], much enhanced from the bulk whose $T_c = 0.1$ K [2], and higher than the isostructural monolayer $1T_d$-WTe$_2$ with its $T_c = 0.7$ K [3,4]. Whereas monolayer MoTe$_2$ is inversion-symmetric, inversion-symmetry is broken in bilayer MoTe$_2$ due to the stacking arrangement, which can change the superconducting properties. Here we will report the quantum transport properties of bilayer and monolayer MoTe$_2$, for a better understanding of its superconductivity, and pursuing topologically non-trivial state in this platform.

12:51PM G48.00009: Strong pairing in two dimensions: Pseudogaps, domes, and other implications*  KATHRYN LEVIN (Presenter), James Franck Institute, University of Chicago, XIAOYU WANG, National High Magnetic Field Laboratory, QIJIN CHEN, University of Science and Technology of China — The recent interest in superconductivity of strongly correlated 2D materials is driven by exciting discoveries of novel superconductors such as magic-angle twisted bilayer graphene (MATBG), FeSe monolayers and transition metal dichalcogenides. These are generally thought to be distinct from BCS-Eliashberg superconductors, and can be argued, from the Uemura plot, to be intermediate between BCS and Bose-Einstein condensation (BCS-BEC). In this talk we compute the Berezinskii-Kosterlitz-Thouless (BKT) transition temperature $T_{BKT}$ and pairing onset $T^*$ as a function of pairing interaction strength $g$ and of density using this crossover theory. Rather than solving directly for the phase stiffness parameter we follow the literature on atomic Bose systems (which is based on a Quantum Monte Carlo analysis) and which constrains the total phase space density at the transition. Our results for $T_{BKT}$ compare favorably with Fermi gas experiments and yield the expected BCS and BEC asymptotes for a film with lattice dispersion. Given the measured $T_{BKT}$, we provide estimates for the pairing gap and for $T^*$ in concrete systems such as MATBG.

In situ mutual inductance measurement of superconducting atomic films: Si(111)-√7 × √3-In and monolayer FeSe on SrTiO₃  
MING-CHAO DUAN (Presenter), YANFU WU, GANG YAO, CANHUA LIU, JINFENG JIA, Shanghai jiao Tong Univ — Many of the novel 2D superconducting films with highly crystalline structure and atomic thickness, fabricated in ultrahigh vacuum chambers, are highly vulnerable to air exposure, making it difficult to measure intrinsic superconducting properties such as zero resistance and perfect diamagnetism with ex situ experimental techniques. To realize vacuum-based measurements, we developed a multifunctional scanning tunneling microscope. The conventional STM probe in the microscope can be switched, under vacuum conditions, to a two-coil probe that can detect whether a material exclude magnetic flux. By using this in situ mutual inductance technique, for the first time, we succeeded in detecting the intrinsic diamagnetic response in both two-atomic-layer indium film on a Si(111) surface and monolayer FeSe films on SrTiO₃. The Si(111)-√7 × √3-In films is expected as a conventional superconductor according to previous STM study. Our diamagnetic measurements verify that the low-temperature variation of penetration depth in Si(111)-√7 × √3-In films follows the BCS theory in the dirty limit. On the other hand, the behavior of monolayer FeSe films on SrTiO₃ in the external magnetic field indicates a vortex melting picture.

Multi-carrier states in the Peierls electron-phonon model  
ALBERTO NOCERA (Presenter), University of British Columbia, JOHN SOUS, Departments of Physics and Chemistry, Columbia University, MONA BERCIU, University of British Columbia — Motivated by the discovery of light polarons and bipolarons in the Peierls electron-phonon model on a one dimensional lattice [1], we numerically study few-carrier states (up to six) using the density matrix renormalization group method. Our results show that a bipolaron liquid is a stable ground state in a wide range of phonon frequencies and electron-phonon interaction strengths. More interestingly, we provide numerical evidence that this homogeneous multi-carrier state for a sufficiently large electron-phonon coupling strength becomes unstable in favor of a multi-polaron complex suggestive of phase separation. We provide analytical arguments in support of our numerics based on an effective multi-body interaction between electrons mediated by phonons [2]. We finally show preliminary results for the case of two coupled chains and discuss the implications of the results for two dimensional systems.

1:27PM G48.00012: Bi$_2$Sr$_2$CaCu$_2$O$_8$ single crystal exfoliation, characterization, and manipulation*  PEDRO MERCADO LOZANO (Presenter), QIANG LI, Condensed Matter Physics and Material Science Division, Brookhaven National Laboratory, YOUNG JAE SHIN, Center for Functional Nanomaterials, Brookhaven National Laboratory, GENDA GU, Condensed Matter Physics and Material Science Division, Brookhaven National Laboratory — Bi$_2$Sr$_2$CaCu$_2$O$_8$ (BSCCO) is a high T$_c$ cuprate superconductor whose layered crystal structure allows the study of thickness dependence of its superconducting properties down to mono-layer. We developed a process to manipulate and analyze BSCCO single crystal and bi-crystal junctions at different film thickness. First, thickness characterization was performed through profile extraction with atomic force microscopy (AFM). A transfer stage was then used to isolate individual flakes of varying thickness in order to study their magnetic response on a SQUID magnetometer. Thin films of less than 100 nm were found to maintain their superconducting properties, which can be inferred from the observation of Meissner effect on the samples. Finally, by using the transfer stage, different layers of BSCCO were rotated around the c-axis and stacked on top of each other. These manipulations enable the study of superconducting properties of bi-crystal junction as a function of the twist angle and the layer thickness.

1:39PM G48.00013: An unexpected charge doping mechanism for quasi-one-dimensional ACr$_3$As$_3$ superconductors  KEITH TADDEI (Presenter), LIURUKARA D SANJEEWA, Oak Ridge National Lab, BING-HUA LEI, YUHAO FU, University of Missouri, QIANG ZHENG, Oak Ridge National Lab, DAVID SINGH, University of Missouri, ATHENA S. SEFAT, CLARINA RELOJ DELA CRUZ, Oak Ridge National Lab — In the race to find topological materials, superconductivity has found renewed interest as potential hosts of Majorana Fermions. However, realizing such states is non-trivial requiring for instance Cooper pairs with finite orbital-momentum or Dirac-like dispersions in the normal state. Recently, a new family of quasi-1D superconductors $A_{1.2}$Cr$_3$As$_3$ ($A$= Alkali metal) was discovered which is interesting in these regards for realizing spin-triplet superconductivity and having Dirac-like crossings near $E_F$. However, its study has been hampered due to extreme air sensitivity and an inability to charge dope. Here, we report results of diffraction studies and DFT work on KCr$_3$As$_3$ which solve both these problems. We show that the reported growth technique inherently intercalates H into the quasi-1D CrAs tubes and that the H acts as an electron donor. Furthermore, we reveal that the reported discrepancy in sample behavior (with some superconducting and others spin-glasses) is actually due to the amount of H. This work suggests a new stoichiometry KH$_{1-x}$Cr$_3$As$_3$, which is air stable and provides a charge doping mechanism. This allows for tuning between frustrated magnetism and superconductivity in a quasi-1D material as well as a potential route to reach the predicted Dirac points.
1:51PM G48.00014: Textured one-dimensional superconducting nanostructures*  
ROBERT LYNN, KRISTINE UNG, LEO V SEMENTILLI, NINA MARKOVIC (Presenter), Goucher College — We have fabricated one-dimensional superconducting nanostructures with precisely controlled texture. The fabrication method that combines nanoscale shadow mask deposition with in situ controlled etching allows nanoscale features to be drawn directly onto the substrate. By controlling the speed with which the shadow mask is translated over the substrate, we can vary the thickness of the nanostructure as it is being deposited. The thickness modulation allows us to control the shape of the superconducting wavefunction in these nanostructured wires, which can be detected in electrical transport measurements at low temperatures and in magnetic field.

2:03PM G48.00015: New Method for Identifying the FFLO State in λ-(BETS)$_2$GaCl$_4$ Using Sample Rotation*  
BRETT LARAMEE (Presenter), RAJU GHIMIRE, CALVIN BALES, Clark University, WILLIAM A CONIGLIO, National High Magnetic Field Laboratory, CHARLES C AGOSTA, Clark University, JOHN A SCHLUETER, National Science Foundation, AKIKO KOBAYASHI, Nihon University — The FFLO state is a state of inhomogeneous superconductivity that exists at high magnetic fields. In specific crystals, the point where Cooper pairs begin to break due to paramagnetic effects, $H_p$, happens before reaching the ultimate critical field, $H_{c2}$. We will present rf penetration depth measurements on the quasi-2D layered organic superconductor λ-(BETS)$_2$GaCl$_4$ (BETS) using a tunnel diode oscillator. The quasi-2D structure of BETS makes features such as $H_{c2}$, the FFLO phase transition, and vortex effects like the lock-in effect highly sensitive to the angle that the conduction planes make with the external field. By rotating the sample in a constant external magnetic field, we can locate points on the FFLO phase line that are not easily identifiable via field sweeps. In addition, we will visualize the FFLO phase transitions in BETS by showing a Field−Angle phase diagram at very low temperature (60 mK). With the addition of this new technique, we have begun constructing a full 3D Field−Angle−Temperature phase diagram of the FFLO state.

*We acknowledge funding from NSF DMR-1905950.

11:15AM G49.00001: Quantum Synchronization and Superconductivity  JONATHAN CURTIS (Presenter), VICTOR GALITSKI, University of Maryland, College Park — Synchronization is a phenomenon whereby weak interactions between oscillators enables a macroscopic phase coherence to develop. While this phenomenon is well known in the context of classical dynamical systems, its extension to quantum oscillators has been relatively un-explored. In this talk we will consider a model where the quantum oscillators are realized by a local superconducting order parameter. We will then study under what circumstances interactions lead to synchronization of the phase, enhancing the phase coherence and superconductivity of the sample.

11:27AM G49.00002: Theory of the nonlinear susceptibility of layered superconductors: application to strontium ruthenate*  FEI CHEN (Presenter), DAMJAN PELC, MARTIN GREVEN, RAFAEL FERNANDES, University of Minnesota — Probing superconducting fluctuations (SF) in unconventional superconductors is essential to elucidate their nature. Much work has been done to elucidate the contributions from SF to the conductivity and the linear susceptibility, disentangling them from normal state contributions can be challenging. An alternative that has been recently explored is to measure the nonlinear susceptibility via third-order magnetic response, which is believed to be dominated by SF above $T_c$. Here, we present a phenomenological theoretical model for the nonlinear susceptibility of layered superconductors. Our model, based on the Lawrence-Doniach functional, predicts power-law behaviors in distinct temperature and magnetic field regimes. Comparison with data from conventional BCS superconductors reveals an excellent agreement between theory and experiment. The same does not happen, however, for oxide superconductors, such as the strontium ruthenate $\text{Sr}_2\text{RuO}_4$ [D Pelc et al., Nat. Commun. 10, 2729 (2019)]. We show that inclusion of disorder can capture some of the experimental features. Finally, we discuss the limitations and possible extensions of our model.

11:39AM G49.00003: Current induced Non equilibrium states In NbTi superconducting Bridge

KHALIL HARRABI (Presenter), King Fahd Univ KFUPM, JEAN PAUL MANEVAL, Physics Department, ENS, Paris, France, LPA —

We report on the discrimination between dissipative states in NbTi superconducting filament on polished crystalline Al2O3 using current driven pulse technique. A current pulse larger than the depairing current ($I_c$) initiates a dissipation in a localized spot. The non-equilibrium state described by the two dissipative mechanism pinpointed as hot spot or phase slip center. A voltage underlines the collapse of the superconductivity show up after a certain delay time $t_d$. We found that the hostspot occurs at low temperature, the phase slip center close to the transition temperature, and proved that a hot spot is ignited by a phase slip center. The thermal relaxation time was ratiocinated from fitting the experimental data with the Time-Dependent Ginzburg-Landau (TDGL) theory due to M. Tinkham at low and high temperature.

*K.H gratefully acknowledges the support of the King Fahd University of Petroleum and Minerals, Saudi Arabia, under the SB181006 DSR project.

11:51AM G49.00004: Photo-Manipulation of Superconductivity in an Extended Hubbard Model

WEI-CHIH CHEN (Presenter), Department of Physics, University of Alabama at Birmingham, YAO WANG, Department of Physics, Harvard University, CHENG-CHIEN CHEN, Department of Physics, University of Alabama at Birmingham — Photo-induced phase transition is a promising approach to engineering material properties and has been demonstrated experimentally in several strongly correlated systems. Here, we numerically study intertwined orders involving charge, spin, and superconductivity in an extended Hubbard model by exact diagonalization on a 16-site square cluster. Our ground-state phases at various carrier doping match previous studies based on mean-field and functional renormalization group methods. On top of the equilibrium ground states, we then investigate the non-equilibrium dynamics of various orders during and after a realistic pump pulse. We found that these intertwined orders and superconducting pairing symmetries can be selectively manipulated through light polarization, frequency, and amplitude. This work shows that using ultrafast light to control superconductivity of desired pairing symmetry is possible.

*This work is supported by NSF Award No. OIA-1738698.
12:03PM G49.00005: Charged fluctuators as a limit to the microscopic and macroscopic coherence of superconductors  
NICOLAS BOURLET (Presenter), CEA-Saclay, HÉLÈNE LE SUEUR, CNRS, ARTIS SVILANS, ANIL MURANI, CEA-Saclay, LAURENT BERGE, LOUIS DUMOULIN, CSNSM, CNRS, PHILIPPE JOYEZ, CEA-Saclay — By analyzing experiments on thin-film resonators of NbSi and TiN, we shed light on a novel decoherence mechanism at work in disordered superconductors. This decoherence is caused by charged Two Level Systems (TLS) which couple to the conduction electrons in the BCS ground state, inducing fluctuations of the kinetic inductance. Standard theories of mesoscopic disordered conductors are used to describe this effect, linking electronic (microscopic) decoherence and electromagnetic (macroscopic) decoherence in superconductors. This model is compared to the so called Generalised Tunelling Model (GTM), used to describe the impact of fluctuating TLS on the dielectric properties of the resonators. Given the omnipresence of charged TLS in solid-state systems, these decoherence mechanisms affects all experiments involving disordered superconductors, and even more so for devices with smaller cross-sections through the new mechanism presented here. In particular, we show it easily explains the poor coherence observed in quantum phase slip experiments and may contribute to lowering the quality factors in disordered superconductor resonators.

12:15PM G49.00006: Analytical Noise Spectra for Chiral d-Wave Superconducting Heterostructures*  
COREY OSTROVE (Presenter), LINDA E REICHL, University of Texas at Austin — We present analytical expressions for the noise spectrum of a chiral d-wave/normal/chiral d-wave Josephson junction. The scattering matrix is derived from the Bogoliubov de-Gennes equations without use of the Andreev approximation. We use the derived scattering coefficients to calculate the current-current correlation function directly and from this the noise spectrum (and in particular the shot noise contribution) is generated. The effects of the chiral nature of the order parameter in the scattering and noise properties of the structures are investigated and are compared to those of those of the non-chiral d-wave order parameter. Recent experimental work has produced a number of candidate materials hypothesized to have chiral d-wave order parameters, which makes theoretical characterization of these structures of particular importance.

*This work is supported by Welch Foundation Grant No. F-1051
JOHN ZASADZINSKI (Presenter), Illinois Institute of Technology, BEVERLY LOWELL, Physics, Northwestern University, NOAH SAMUELSON, Illinois Institute of Technology. — The above-gap, SIN tunneling spectral dip (bosonic mode) feature in the bilayer cuprate Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ (Bi2212) is highly reproducible and its doping dependence links it to the resonance spin excitation. SIS junctions on Bi2212 reveal a strongly enhanced dip strength and symmetric, decreasing conductance backgrounds, indicating the elastic tunneling origin of the bosonic mode and the connection to the pairing self-energy. The observation of similar bosonic mode features in the tunneling spectra of Fe-based superconductors and other cuprate superconductors is discussed. Scanning tunneling spectroscopy (STS) on FeSe reveals a similar background shape to Bi2212 indicating the symmetric bosonic mode features also are dominated by elastic tunneling. Disorder effects which show up as a depairing rate, $\Gamma$, in the fitting of the density of states (DOS) become increasingly important for lower Tc single-layer cuprates. It is demonstrated that SIS break junctions and intrinsic c-axis junctions allow the observation of a bosonic mode in strongly disordered Bi2201 with Tc values $\leq$ 5K. The scaling of $\Omega$ with Tc over nearly two decades, and over two different classes of superconductors suggests that the bosonic mode is a universal signature of unconventional superconductivity.

12:39PM G49.00008: Dynamics of phase coherence in superconducting cuprates upon mid-infrared photoexcitation*  
ANGELA MONTANARO (Presenter), FRANCESCA GIUSTI, DANIELE FAUSTI, Univ of Trieste - Trieste. — Superconducting fluctuations in optimally-doped cuprates are known to survive well above the critical temperature, making these systems a perfect playground to investigate the possibility of transiently controlling superconductivity through ultrashort light pulses. While it has been widely shown that high photon energy electromagnetic fields melt the superconducting phase [1], there are evidences that mid-infrared photoexcitation can trigger the onset of superconductivity in regions of the phase diagram in which the system is not superconducting at the equilibrium [2,3]. We performed measurements on optimally-doped Y-Bi2212 by a 3-pulse technique which allows to disentangle these two effects. The approach is based on selectively destroying the superconducting state using a visible pump, and then further exciting the sample by means of a mid-infrared source. By probing the system through a broadband supercontinuum, we reveal the details of the transient dynamics of the condensate phase coherence solely driven by mid-infrared pulses with photon energy close to the superconducting gap.

12:51PM G49.00009: Josephson phenomena in Van der Waals heterostructures* LIAM FARRAR (Presenter), Physics, University of Bath, GEETHA BALAKRISHNAN, Physics, University of Warwick, SIMON J BENDING, Physics, University of Bath —

It is well established that a dissipationless supercurrent can flow across a junction at the interface between two superconductors due to a phenomenon known as the Josephson effect. This concept has recently been extended to 2D superconductors, where Josephson effects have been successfully measured at the interface between two misaligned NbSe2 flakes [1]. In this talk we discuss progress made in the formation of Josephson junctions between electrodes with different superconducting order parameters by two methods; homojunctions formed by stacking two exfoliated flakes of the same superconductor with a well-defined twist angle, and heterojunctions formed by stacking two different superconductors (eg. NbSe2, NbS2, BSSCO). These structures behave as underdamped Josephson junctions, exhibiting strong zero-bias supercurrents as well as clear signatures of the superconducting gaps. Finally, we will discuss the applications of this approach to the formation of more complex superconducting devices such as superconducting quantum interferometer devices (SQUIDS).

This work was supported by EPSRC, UK (EP/L015544/1).

1:03PM G49.00010: Vortex effects as an indication of a transition to the FFLO state* CALVIN BALES (Presenter), Physics, Brown University, RAJU GHIMIRE, Clark University, VESNA F MITROVIC, Physics, Brown University, JOHN A SCHLUETER, National Science Foundation, AKIKO KOBAYASHI, Nihon University, CHARLES C AGOSTA, Clark University — The FFLO state is an exotic superconducting state that allows materials to remain in a superconducting state at higher fields than the paramagnetic limit where a magnetic field would normally break the singlet state of the Cooper pairs. The angular dependence of the rf penetration depth of the sample relative to the field is sensitive to distinct data signatures such as vortex lock-in where the Josephson vortices are very lightly pinned and increase the penetration depth. This presentation will discuss the process by which we were able to analyze these vortex data signatures as an indication of vortex lock-in and the transition to the FFLO state. The analysis of angular and field sweeps as well as the transformation from angular sweeps to field sweeps and vice versa make evident the validity of the features we are seeing as well as the connections between the features and vortex motion. This presentation will focus on the results of measurements of λ-(BETS)2GaCl4 and κ-(ET)2Cu(NCS)4 superconductors.

*We acknowledge funding from NSF DMR-1905950. A portion of this work was performed at the National High Magnetic Field Laboratory, which is supported by NSF Cooperative Agreement No. DMR-11157490 and the state of Florida.
1:15PM G49.00011: Imaging dissipative current in superconducting Niobium film using scanning SQUID susceptometry  ELI MUELLER (Presenter), JOHN ROBERT KIRTLEY, RUBY SHI, HUIYUAN MAN, KATHRYN ANN MOLER, Stanford Univ — The quasiparticle density of states is a strong diagnostic of the superconducting gap and may be observed as dissipation in two coil mutual inductance experiments. Mutual inductance experiments have typically been limited to millimeter spatial resolution and therefore measure nonzero impedance resulting from motion of vortices. Susceptibility measurements with greater spatial resolution may be able to detect the additional dissipation resulting from scattering of excited quasiparticles. Scanning Superconducting QUantum Interference Device (SQUID) susceptibility measurements offer micron scale spatial resolution with the in-phase component measuring superfluid density and the quadrature component measuring dissipation. In this talk, we report on micron scale scanning SQUID susceptometry measurements on a Niobium film in an effort to observe the frequency and temperature dependence of quasiparticle scattering. Successfully observing the temperature dependence of quasiparticle excitations in Niobium would be a proof of concept to measure dissipation in unconventional superconductors with micron scale spatial resolution.

1:27PM G49.00012: Dynamic Evolutions of Flux Distributions in a Superconductor by a Pulsed Current*  HODAKA KUROKAWA (Presenter), YUTO KINOSHITA, FUYUKI NABESHIMA, MASASHI TOKUNAGA, ATSUTAKA MAEDA, Univ of Tokyo — The dynamics of vortices in a superconductor has long been investigated because of its practical importance for the application of the superconducting magnets. The direct imaging of flux-density distributions must be powerful for the understandings of the dynamics of vortices. However, observations of the time-evolution of the flux-density distributions have been scarcely reported. From this viewpoint, it is still unclear how the static state of vortices collapses into the flow state. Hence, we observed the changes of flux–density distributions in a superconductor by a pulsed current with the magneto-optical microscopy. The flux-density distributions in a NbN film were measured up to 10000 frames per second. We investigated for different initial flux distributions in a comparative manner; the field-cooled state, the remanent state, the zero-field-cooled (ZFC) state. In the remanent state and the ZFC state, local reconfiguration of vortices occurred even below the critical current, which was qualitatively explained within the critical state model. However, some deviations between experiments and the theory were observed in the ZFC state, indicating that the current flows in the sample even far below the critical current.

1:39PM G49.00013: Effect of electron irradiation on rf-susceptibility of ferromagnetic superconductor EuFe$_2$(As,P)$_2$* SUNIL GHIMIRE (Presenter), KYUIL CHO, MAKARIY A TANATAR, Ames Laboratory, TSUYOSHI TAMEGAI, Department of Applied Physics, University of Tokyo, RUSLAN PROZOROV, Ames Laboratory — High resolution AC magnetic susceptibility was measured in single crystals of ferromagnetic superconductor (T$_C$=24K, T$_{Curie}$=18K), EuFe$_2$(As,P)$_2$ using tunnel diode resonator (TDR) in zero and in finite external DC magnetic fields. The same sample was irradiated with 2.5 MeV electrons at a dose that caused substantial changes of all features. Based on these and literature results, the intricate interplay between superconductivity and ferromagnetism in this unique system will be discussed.

1:51PM G49.00014: Rotational transition, domain formation, dislocations and defects in vortex systems with combined six- and 12-fold anisotropic interactions* MACIEJ W OLSZEWSKI, MORTEN ESKILDSEN (Presenter), Department of Physics, University of Notre Dame, CHARLES REICHHARDT, CYNTHIA REICHHARDT, Theoretical Division, Los Alamos National Laboratory — We introduce a new model for a pairwise repulsive interaction potential of vortices in a type-II superconductor, consisting of superimposed six- and 12-fold anisotropies. Using numerical simulations we study how the vortex lattice configuration varies as the magnitudes of the two anisotropic interaction terms change. A triangular lattice appears for all values, and rotates through 30° as the ratio of the six- and 12-fold anisotropy amplitudes is varied. The transition causes the VL to split into domains that have rotated clockwise or counter-clockwise, with grain boundaries that are "decorated" by dislocations consisting of five- and seven-fold coordinated vortices. We also find intra-domain dislocations and defects, and characterize them in terms of their energy cost.

Session G50 DCMP: Quantum Criticality Theory Mile High Ballroom 1C - Eun-Gook Moon, KAIST
11:15AM G50.00001: Quantum Criticality of Semi-Dirac Fermions  MIKOLAJ URYSZEK (Presenter), ELLIOT CHRISTOU, Univ Coll London, AKBAR JAEFARI, Western New England University, FRANK KRUGER, Univ Coll London, BRUNO UCHOA, University of Oklahoma — Two-dimensional semi-Dirac fermions are quasiparticles that disperse linearly in one direction and quadratically in the other. We investigate instabilities of semi-Dirac fermions toward charge and spin density wave and superconducting orders, driven by short-range interactions. We analyze the critical behavior of the Yukawa theories for the different order parameters using Wilson momentum shell renormalization group. We generalize to a large number of fermion flavors, N, to achieve analytic control in 2+1 dimensions and calculate critical exponents at one-loop order, systematically including universal 1/N corrections. The anomalous dimension of the fermion fields vanishes in the large N limit, consistent with a recovery of Fermi-liquid behaviour. However, many other unusual features persist. We show that this is a consequence of non-analytic terms in the mean-field free energy of semi-Dirac fermions.

11:27AM G50.00002: Quantum Criticality of Multiband Polar Metals*  PAVEL VOLKOV (Presenter), PIERS COLEMAN, PREMALA CHANDRA, Department of Physics and Astronomy, Center for Materials Theory, Rutgers University — Quantum criticality in metallic systems leads to a variety of exotic behaviors, that sensitively depend on the type of the transition. The case of a polar transition in a metal, structurally identical to a ferroelectric transition in an insulator, has received attention recently due to the discovery of a number of metallic compounds where a polar order exists.

We show that quantum criticality of multiband polar metals is of particular interest, as a strong coupling of the charge carriers to the critical mode can be realized near the band crossings in momentum space. We provide a comprehensive classification of the possible emerging quantum critical behaviors and find evidence for strong interaction effects and, in some cases, non-Fermi liquid physics. The critical properties are found to depend on the type of band crossing as well as dimensionality. Experiments, that can allow to probe the emergent behavior, and implications for existing materials are discussed.

*P. Volkov is supported by a Rutgers Center for Materials Theory Postdoctoral Fellowship.
11:39AM G50.00003: Deconfined quantum criticality in the 2D J-Q model*  BOWEN ZHAO  
(Presenter), Boston Univ, ANDERS W SANDVIK, Boston Univ/ IOP-CAS, Beijing — The deconfined quantum critical point (DQCP) was proposed as a new scenario for quantum phase transitions fifteen years ago [1] and is still an enigmatic concept, with no general consensus on its existence. To test the DQCP proposal, which is based on a quantum field theory that cannot be solved, numerical studies of various lattice models have been considered. While no direct signs of discontinuities have been observed in the finite-size scaling, there are scaling anomalies that have led to speculations of a weak first-order transition described by a non-unitary conformal field theory [2]. Another possibility is that the transition is continuous but violates standard scaling laws. The observed finite-size scaling violations can be described phenomenologically by a scaling form with two relevant fields that are tuned by the same parameter in the Hamiltonian [3]. We will discuss recent work aimed at high-precision tests of this type of scaling by doing large scale calculation of the J-Q model which can realize the quantum phase transition between the antiferromagnetic state and a valence-bond solid state.

*This work is supported by NSF Grant No. DMR-1710170 and the Simons Foundation.

11:51AM G50.00004: Quantum Critical Ballistic Transport in Two-Dimensional Fermi Liquids*  MANI CHANDRA (Presenter), GITANSH KATARIA, DESHDEEP SAHDEV, Quazar Technologies — We show that the ballistic regime in two-dimensional Fermi liquids is a quantum critical point (QCP) on the regime boundary separating Ohmic and hydrodynamic transport. The QCP corresponds to a free conformal field theory (CFT) with a dynamical scaling exponent $z = 1$. Its nontrivial aspects emerge in device geometries with shear, wherein the regime has an intrinsic universal dissipation, a nonlocal current-voltage relation, and exhibits the critical scaling of the underlying CFT. The Fermi surface has electron-hole pockets across all angular scales and the current flow has vortices at all spatial scales. The scale-invariant spatial structure is much richer than that of an interaction-dominated hydrodynamic regime, which only has a single vortex at the device scale. We animate the emergence of critical spatial (vimeo.com/365020115) and Fermi surface (vimeo.com/364982637) fluctuations as experimental parameters are tuned to the QCP. The vortices clearly demonstrate that Pauli exclusion alone can produce collective effects, with low-frequency AC transport mediated by vortex dynamics (vimeo.com/366725650).

12:03PM G50.00005: Collusion of Interactions and Disorder at the Superfluid-Insulator Transition: A Dirty 2d Quantum Critical Point*  HART GOLDMAN (Presenter), University of Illinois at Urbana-Champaign, ALEX THOMSON, California Institute of Technology, LAIMEI NIE, University of Chicago, ZHEN BI, Massachusetts Institute of Technology — We study the stability of the Wilson-Fisher fixed point of the quantum O(2N) vector model to quenched disorder in the large-N limit. While a random mass is strongly relevant at the Gaussian fixed point, its effect is screened by the strong interactions of the Wilson-Fisher fixed point. This enables a perturbative renormalization group study of the interplay of disorder and interactions about this fixed point. We show that, in contrast to the spiralling flows obtained in earlier double-ε expansions, the theory flows directly to a quantum critical point characterized by finite disorder and interactions. The critical exponents we obtain for this transition are in remarkable agreement with numerical studies of the superfluid-Mott glass transition. We additionally discuss the stability of this fixed point to scalar and vector potential disorder and use proposed boson-fermion dualities to make conjectures regarding the effects of weak disorder on dual Abelian Higgs and Chern-Simons-Dirac fermion theories when N=1.

*NSF GRFP under Grant No. DGE-1144245, the Kadanoff Fellowship at the University of Chicago, the Pappalardo Fellowship at MIT, the Walter Burke Institute for Theoretical Physics at Caltech, and the Caltech IQIM (Gordon and Betty Moore Foundation Grant GBMF1250).

12:15PM G50.00006: Deconfined quantum critical point in the extended Hubbard model: a sign-problem-free quantum Monte Carlo study  XUN CAI (Presenter), BOHAI LI, Tsinghua University, ZIXIANG LI, University of California, Berkeley, HONG YAO, Tsinghua University — Deconfined quantum critical point (DQCP) describes a type of quantum phase transitions at T=0 beyond Landau paradigm, where a continuous transition appears between ordered phases with incompatible broken symmetries. Convincing evidences of DQCP in correlated fermionic systems are scarce. Here we study the quantum phase diagram and phase transition on an extended Hubbard model of fermions on the square lattice. By performing determinant quantum Monte Carlo simulation, we establish the ground-state phase diagram of this model, and more intriguingly, show convincing evidence of a continuous phase transition between valence-bond-solid (VBS) and antiferromagnetic (AF) phases when the interaction strength is varied. We believe that our study provides a novel platform for the investigation of DQCP in the strongly correlated fermionic systems.
12:27PM G50.00007: Deconfined quantum criticality and emergent SO(5) symmetry in fermionic systems  
ZIXIANG LI, UC Berkeley, SHAOKAI JIAN, HONG YAO (Presenter), Tsinghua University — Deconfined quantum criticality with emergent SO(5) symmetry in correlated systems remains elusive. Here, by performing numerically-exact state-of-the-art quantum Monte Carlo (QMC) simulations, we show convincing evidences of deconfined quantum critical points (DQCP) between antiferromagnetic and valence-bond-solid phases in the extended Hubbard model of fermions on the honeycomb lattice with large system sizes. We further demonstrate evidences of the SO(5) symmetry at the DQCP. Moreover, it is the first time that the critical exponents obtained at the DQCP are consistent with the rigorous conformal bounds. Consequently, we establish a promising arena of DQCP with emergent SO(5) symmetry in interacting systems of fermions. Its possible experimental relevances in correlated systems such as graphene-family materials will be discussed briefly [1].

12:39PM G50.00008: Exploring a quantum critical point in the 3D Hubbard model using the dynamical cluster approximation  
SAMUEL KELLAR (Presenter), KA-MING TAM, Louisiana State University, Baton Rouge — This research simulates the single band three dimensional Hubbard Model using the dynamical cluster approximation. Away from half-filling the system appears to undergo a quantum phase transition driven by the chemical potential or doping level. The quasiparticle weight, extracted from the self-energy, is used to identify the emergence of a Fermi liquid phase. At lower fillings the quasiparticle weight maintains a finite value consistent with a Fermi liquid state. Nearer to half-filling the quasiparticle weight tends towards zero suggesting a non-Fermi liquid state. We also search for evidence of a marginal Fermi liquid state, a signature of the quantum criticality. In order to complete this simulation efficiently the continuous time quantum Monte Carlo method is run on a massively parallel simulation.

12:51PM G50.00009: Many-body chaos in the antiferromagnetic quantum critical metal  
PETER LUNTS (Presenter), Simons Foundation, AAVISHKAR PATEL, Physics, Berkeley — Recently, the scrambling rate as defined from the exponential growth of regularized out-of-time-ordered correlators has been used as a measure of integrability in quantum many-body systems. We compute the scrambling rate at the antiferromagnetic (AFM) quantum critical point, using the fixed point theory of Phys. Rev. X 7, 021010 (2017). At this strongly coupled fixed point, there is an emergent small control parameter $w$ that is a ratio of natural parameters of the theory. The strong coupling is unequally felt by the two degrees of freedom: the bosonic AFM collective mode is heavily dressed by interactions with the electrons, while the electron is only marginally renormalized. The scrambling rates of both degrees of freedom are linear in temperature (up to logarithms), but come with very different powers of $w$, indicating the different "degrees of integrability" of the two sectors of the theory. Although the interaction strength is of order unity, the larger Lyapunov exponent is still parametrically smaller than the universal upper bound. We also show that due to the non-local nature of the boson propagator, its effective "butterfly velocity" of the chaos front is infinite.
1:03PM G50.00010: Monopole hierarchy at a quantum critical point between a Dirac spin liquid and an antiferromagnet*  

ERIC DUPUIS (Presenter), WILLIAM WITCZAK-KREMPA, Universite de Montreal — Certain frustrated 2D quantum magnets may be described at low energy by a Dirac spin liquid (DSL) which is a version of quantum electrodynamics with 2N flavors of two-component gapless Dirac spinons. A DSL also hosts monopole excitations due to the compactness of the emergent U(1) gauge field. These drive the confinement of the spinons. We revisit the hierarchy among monopole operators with different quantum numbers at the quantum critical point (QCP) between a DSL and an antiferromagnet. By obtaining the scaling dimension of monopole operators while constraining their spin quantum number, we explicitly show their organization into multiplets of the QCP flavor symmetry group SU(2)xSU(N). We also discuss 1/N corrections to the scaling dimension of monopoles at a critical point between a DSL and a chiral spin liquid.

1:15PM G50.00011: The Hall Effect and Dynamical Scaling about the Quantum Critical Point in Elemental Chromium  

STEPHEN ARMSTRONG (Presenter), DANIEL SILEVITCH, THOMAS F ROSENBAUM, California Institute of Technology — Elemental chromium is a spin-density-wave (SDW) antiferromagnet that can be tuned through a second order quantum phase transition by the application of 10 GPa of pressure. A nesting condition in the paramagnetic Fermi surface partially gaps the Fermi surface and forms the SDW. Since the Hall coefficient directly probes properties of the Fermi surface, it is an effective tool to investigate the evolution of the Fermi surface in the quantum critical regime, where there are indications of strong-coupling physics. In the low temperature limit, the Hall coefficient varies rapidly with pressure across the quantum critical point. By extending this measurement to higher temperatures, we are able to track the P-T dependence of this crossover and test analogies to the pseudogap phase in the superconducting cuprates. The temperature dependence of the width of this crossover constrains theories of dynamical scaling at the quantum critical point.
1:27PM G50.00012: Optical Conductivity of the Two Dimensional Anti-ferromagnetic Quantum Critical Metal* ASHUTOSH SINGH (Presenter), ANTON BORISSOV, SUNG-SIK LEE, McMaster University — In the two-dimensional anti-ferromagnetic quantum critical metal, coherent quasi-particle(s) ceases to exist at the hot spots due to strong coupling with soft spin fluctuations. Over an intermediate energy scale, physical responses of the non-Fermi liquid is controlled by the nesting angle between patches of Fermi surface connected by the anti-ferromagnetic wavevector. For instance, the anomalous dimension of electron(s) at the hot spots defined over an intermediate energy scale decreases with decreasing nesting angle due to an increased damping of spin fluctuations by particle-hole excitation. In this work, we compute the optical conductivity of the non-Fermi liquid state as a function of the nesting angle. Remarkably, the weight of the conductivity that scales anomalously with frequency due to the soft spin fluctuations is enhanced as the nesting angle decreases. This is attributed to the fact that the increased number of electrons that are subject to scattering with spin fluctuations overcompensates the decreased scattering rate of individual electrons.

1:39PM G50.00013: Quantum criticalities with lattice vibrations* SANGEUN HAN (Presenter), Department of Physics, KAIST, JUNHYUN LEE, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, College Park, EUN-GOOK MOON, Department of Physics, KAIST — Quantum criticality is one of the most important concepts in modern condensed matter physics, as novel physics may arise in the vicinity of the quantum critical point by quantum fluctuations. These fluctuations inevitably couple to lattice vibrations in real materials due to the lattice structures. It is well understood that a class of thermal continuous transitions on lattices is eventually destabilized by either macroscopic instability of lattice structures or induced first-order symmetry breaking transitions. However, for the quantum phase transition, little is known about its consequences. Here, we demonstrate that such interplay between quantum criticality and lattice vibration leads to a new class of quantum many-particle phenomena. Moreover, we suggest a new stability condition for these criticalities which generalizes the specific-heat criterion of thermal transitions to a quantum version. Our results suggest a new direction to find novel quantum criticalities in nature.

1:51PM G50.00014: Novel Criticality of Dirac Fermions from Lattice Symmetry Breaking
FRANK KRUGER (Presenter), ELLIOT CHRISTOU, Univ Coll London, FERNANDO DE JUAN, IKERBASQUE
— We consider the role of spontaneous lattice symmetry breaking in strongly interacting two
dimensional Dirac systems. The fermion induced quantum (multi-)criticality is described by Dirac
fermions coupled to a dynamical order parameter that is composed of mass and emergent
gauge fields. This is illustrated for the example of translational symmetry breaking due to charge-
density wave order on the honeycomb lattice. Using a renormalization-group analysis we find
that the putative emergent Lorentz invariance is violated. Finally, we identify that topological
phase transitions are well described by this effective field theory.

*F. K. acknowledges financial support from EPSRC under Grant EP/P013449/1.

2:03PM G50.00015: Kardar-Parisi-Zhang universality from soft gauge modes
VIR BULCHANDANI (Presenter), University of California, Berkeley — The emergence of superdiffusive spin
dynamics in integrable classical and quantum magnets is well established by now, but there is no
generally valid theoretical explanation for this phenomenon. A fundamental difficulty is that the
hydrodynamic fluctuations of conserved quasiparticle modes are purely diffusive. We propose a
"hydrodynamic Higgs mechanism" in isotropic integrable magnets, which generates soft gauge
modes that are decoupled from the quasiparticle sector. We show that the coarse-grained time
evolution of these modes lies in the Kardar-Parisi-Zhang universality class of dynamics.

Session G51 DCMP DMP: Graphene: Electronic Structure and
Interactions III; Moire, Correlations, & Topology

Mile High Ballroom 1D - Dmitry Shcherbakov, Ohio State Univ - Columbus

11:15AM G51.00001: Electronic Collective Modes in Twisted Bilayer Graphene
NICHOLAS WERNER (Presenter), ANDREAS BILL, Department of Physics & Astronomy, California State University,
Long Beach, CA 90840 — Twisted Bilayer Graphene (TBLG) is a structure composed of two
graphene sheets stacked with a relative twist angle between them. Cao et al. [Nature 556, 43
(2018)] reported the discovery of a superconducting state in TBLG at a "magic angle" of about
1.05°. There is no consensus yet on the mechanism that causes this state.
We study electronic collective modes in bilayer graphene at various twist angles with a particular
emphasis on low-energy plasmons. The calculation is performed for two band structures: the
tight-binding model that displays a long-range periodic Moiré pattern at commensurate twist
angles, and the continuum model that allows for the calculation of collective modes at and near
the magic angle. We discuss the implications of the electronic collective modes spectrum for
superconductivity in twisted bilayer graphene.
11:27AM G51.00002: Charge Smoothening and Band Flattening due to Hartree corrections in Twisted Bilayer Graphene  LOUK RADEMAKER (Presenter), Univ of Geneva, PAULA MELLADO, Adolfo Ibáñez University, Chile, DMITRY ABANIN, Univ of Geneva — Doping twisted bilayer graphene away from charge neutrality leads to an enormous buildup of charge inhomogeneities within each Moiré unit cell. Here we show, using unbiased real-space self-consistent Hartree calculations on a relaxed lattice, that Coulomb interactions smoothen this charge imbalance by changing the occupation of earlier identified ‘ring’ orbitals in the AB/BA region and ‘center’ orbitals at the AA region. For hole doping, this implies an increase of the energy of the states at the \( \Gamma \) point, leading to a further flattening of the flat bands and a pinning of the Van Hove singularity at the Fermi level. The charge smoothening will affect the subtle competition between different possible correlated phases.

11:39AM G51.00003: Electrostatic Tuning of the Coulomb Interaction in Single Layer Graphene  NICHOLAS DALE (Presenter), RYO MORI, IQBAL UTAMA, CLAUDIA FATUZZO, University of California, Berkeley, JONATHAN DENLINGER, Advanced Light Source, CONRAD STANSBURY, SIHAN ZHAO, KYUNGHOO LEE, University of California, Berkeley, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute of Materials Science, FENG WANG, ALESSANDRA LANZARA, University of California, Berkeley — The Landau-Fermi Liquid Theory maps an interacting liquid of electrons to a non-interacting gas of quasiparticles. This picture breaks down in Graphene, because the bare Coulomb interaction is preserved near the charge neutrality point. In this talk, I will discuss recent in-operando angle-resolved photoemission studies on single layer graphene where we directly visualize modifications of its electronic band structure upon tuning the Fermi Energy.

11:51AM G51.00004: Streamlining twisted bilayer graphene measurements*  JOE FINNEY (Presenter), AARON SHARPE, ARTHUR W BARNARD, CONNIE HSUEH, ELI J FOX, Stanford Univ, KENJI WATANABE, TAKASHI TANIGUCHI, NIMS, MARC KASTNER, MIT, DAVID GOLDHABER-GORDON, Stanford Univ — Twisted bilayer graphene (TBG) has emerged as a promising platform for studying strongly correlated physics. When the twist angle is near the magic angle of approximately one degree, transport measurements have revealed a host of interesting phenomena including correlated insulating states, superconductivity, and ferromagnetism. However, fabricating and effectively measuring TBG samples remains challenging. The twist angle varies widely from sample to sample, and even from contact to contact within the same sample. In this work, I present a few tools we have used in order to streamline the process of making and measuring TBG samples, along with some interesting results encountered along the way.

*This work is supported by the Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, under Contract DE-AC02-76SF00515.
Twisted bilayer graphene has recently gained significant attention due to the discovery of superconductivity and correlated insulating behavior near the magic angle of 1.1 degrees. Other twisted 2D van der Waals heterostructures are expected to host similar phenomena. Thus, methods for consistent and precise fabrication of twisted 2D materials are essential to enable their further study. We discuss the dry transfer technique that enables high accuracy rotational alignment that we have used to fabricate magic angle twisted bilayer graphene devices for scanning probe microscopy measurements. Using low temperature scanning tunneling microscopy and spectroscopy, we have verified the localization properties of the flat bands and directly probed the correlated insulating states at commensurate filings. These results can lead to a better understanding of the local electronic properties of magic angle twisted bilayer graphene.

The work at the University of Arizona was supported by the National Science Foundation under grants DMR-1708406 and EECS-1607911

Recently, signatures of quantum anomalous Hall states with spontaneous ferromagnetism were observed in twisted bilayer graphenes (TBGs) near 3/4 filling [Science 365, 605-608 (2019), arXiv: 1907.00261]. Importantly, it was demonstrated that an extremely small current can switch the direction of the magnetization. This opens the prospect of realizing low energy dissipation magnetic memories. However, the mechanism of the current-driven magnetization switching is poorly understood as the charge currents in graphene layers are generally believed to be non-magnetic. In this work, we demonstrate that, in TBGs, the twist-induced reduction of lattice symmetry allows a charge current to generate net orbital magnetization at a general filling factor through magnetoelectric effects. Substrate-induced strain and sublattice symmetry breaking further reduce the symmetry such that an out-of-plane orbital magnetization can be generated. Due to the large non-trivial Berry phase of the bands, the orbital magnetization of a Bloch state can be as large as tens of Bohr magnetons and therefore a small current would be sufficient to generate a large orbital magnetization. We further demonstrate how the charge current can switch the magnetization of TBGs as observed in experiments.

HKRGC
It has been recently established that optoelectronic and non-linear transport experiments can give direct access to the dipole moment of the Berry curvature in non-magnetic and non-centrosymmetric materials. Thus far, non-vanishing Berry curvature dipoles have been shown to exist in materials with substantial spin-orbit coupling where low-energy Dirac quasiparticles form tilted cones. Here, we prove that this topological effect does emerge in two-dimensional Dirac materials even in the complete absence of spin-orbit coupling. In these systems, it is the warping of the Fermi surface that triggers sizeable Berry dipoles. We show indeed that uniaxially strained monolayer and bilayer graphene, with substrate-induced and gate-induced band gaps respectively, are characterized by Berry curvature dipoles comparable in strength to those observed in monolayer and bilayer transition metal dichalcogenides.

References:

Interlayer electron-electron (el-el) and electron-phonon (el-ph) interactions emerge from the coupling of atomic layers in 2D heterostructures and are essential for describing their physical properties. The additional possibility of controlling the twisting angle between layers opens new possibilities for tunable devices. Raman spectroscopy is a fundamental tool to investigate el-ph interactions and the possibility of using multiple-excitation spectroscopy allows the distinction between intralayer and interlayer el-ph interactions. We will discuss a resonance Raman study of twisted bilayer graphene (TBG) samples with different twisting angles and measured using different laser lines. Results show that the extra Raman peaks that appear in the spectra come from different physical mechanisms: the intralayer process, where the el-ph scattering occurs in a single graphene layer and the other layer only imposes a periodic potential that scatters the excited electron, and the interlayer el-ph process, where the scattering occurs between states in the Dirac cones of adjacent graphene layers.
12:51PM G51.00009: Atomistic Calculation of Electron-Phonon Coupling in Twisted Graphene Layers

YOUNG WOO CHOI (Presenter), HYOUNG JOON CHOI, Department of Physics, Yonsei University, Seoul, 03722, Korea — We investigate electron-phonon coupling in twisted graphene layers based on atomistic calculations of electronic structure, phonon dispersion, and electron-phonon matrix elements. First, we calculate twisted double bilayer graphene (TDBG). Then, we analyze the characteristics of important phonon modes that have strong contributions to the total coupling strength. Also, we compare the electron-phonon coupling in TDBG and magic-angle twisted bilayer graphene in the context of the recent experimental observations of superconductivity in these systems. Our work provides microscopic understanding of the electron-phonon coupling in twisted graphene layers, which is a basis for explaining superconducting mechanism of these systems.

1:03PM G51.00010: Observation of Substrate Induced Multiple Dirac Cones in Graphene/ SiC Heterostructure

QIANGSHENG LU (Presenter), JACOB COOK, XIAOQIAN ZHANG, GUANG BIAN, Univ of Missouri - Columbia — The coupling between epitaxial graphene layers and various substrates give rise to many interesting phenomena such as the energy gap at the Dirac node and double Dirac cones. Electronic structure of graphene is modulated by the substrate effects. In this work, we measured the electronic structure of bilayer graphene/SiC heterostructure. Apart from the duplicated Dirac cones arising from the interaction with the interfacial reconstruction, 24 additional Dirac cones are clearly observed by angle-resolved photoemission spectroscopy (ARPES) within the 1st Brillouin zone of graphene. These 24 Dirac cones are directly generated from the coupling between graphene layers and the supporting SiC lattice, a result consistent with our tight-binding simulations. This work paves the way for understanding the direct electronic coupling between graphene and SiC substrates.

G51.00013: Hofstadter butterfly and quantum Hall effect in twisted double bilayer graphene*  JOHN A. CROSSE, Arts and Sciences, NYU Shanghai, MIKITO KOSHINO, Department of Physics, Osaka University, PILKYUNG MOON (Presenter), Arts and Sciences, NYU Shanghai — In this talk, I will discuss the energy spectrum and quantum Hall effect in twisted double bilayer graphene (TDBG, a pair of Bernal-stacked bilayer graphenes stacked with a rotational stacking fault). The electronic band structures of TDBG with AB-AB configuration and AB-BA configuration look similar in the absence of magnetic field, but their topological nature are different [1]. Therefore, the twins of AB-AB and AB-BA TDBG exhibit very different spectrum in magnetic field, by directly reflecting the difference in Chern numbers of the two pair structures [2]. For example, the first gap in the electron side of AB-AB TDBG remains opened in increasing magnetic fields, while that of AB-BA TDBG vanishes at some points due to the non-zero valley Chern number in AB-BA TDBG.

Session G52 DMP: Focus Topic: Surface, Interface, and Thin Film Science of Organic Molecular Solids I Mile High Ballroom 1E - Daniel Dougherty, North Carolina State University - Tag(s): Focus
11:15AM G52.00001: Using Deposition Rate to Control Liquid Crystal-like Order in Vapor Deposited Organic Glasses*  
CAMILLE BISHOP (Presenter), University of Wisconsin - Madison, JACOB THELEN, National Institute of Standards and Technology, YUHUI LI, University of Wisconsin - Madison, ELIOT H GANN, National Institute of Standards and Technology, MICHAEL TONEY, SLAC National Accelerator Laboratory, LIAN YU, University of Wisconsin - Madison, DEAN DELONGCHAMP, National Institute of Standards and Technology, MARK EDIGER, University of Wisconsin - Madison — Physical vapor deposition can prepare glassy materials with high degrees of structural anisotropy compared to liquid-cooled glasses. In this work, Posaconazole, a molecule with no known liquid crystal phases, is vapor-deposited to create smectic-like glasses with a high degree of orientational and positional order [Bishop et. al. PNAS 116, 21421 (2019)]. Deposition parameters are varied to prepare glasses with a range of liquid crystal-like order. We show that increasing the substrate temperature and decreasing the deposition rate have the same effect upon vapor-deposited glass structure, and describe the relationship using a “Deposition Rate-Substrate Temperature Superposition”. We expect that this superposition principle can be used to understand surface dynamics during vapor deposition, in order to optimize structural order in glasses for organic electronic applications.

*This research was primarily supported by NSF through the University of Wisconsin Materials Research Science and Engineering Center (DMR-1720415).

11:27AM G52.00002: 2D organic layers on surfaces: self-assembly and electronic structure*  
[Invited] SYLVIE RANGAN (Presenter), ROBERT ALLEN BARTYNSKI, Rutgers University, New Brunswick — Understanding the basic mechanisms leading to the formation of 2D organic layers on surfaces, either via Van der Waals, ionic or covalent interactions, is a necessary step toward the development of controlled and ordered organic layers, for technological applications such as homogeneous doping of graphene or 2D organic topological insulators. Using a combination of scanning tunnel microscopy, various electron spectroscopies techniques and ab-initio calculations, we have studied several aspects of the self-assembly and reactivity of particularly interesting model systems: Zinc tetraphenylporphyrins (ZnTPP) on single crystal surfaces.

First, we have explored the delicate balance of forces during the self-assembly process of ZnTPPs on metal single crystal surfaces. It is shown that molecule/molecule and molecule/surface interactions, as well as accumulated surface stress, all play an important role in determining self-assembly. In particular, it is shown that self-assembly can be kinetically trapped into metastable phases different from typical equilibrium outcomes. Furthermore, it is possible to generate under certain conditions on self-assembled ZnTPP arrays, surface mediated chemistry that leads, to site-selective dehydrogenation and intramolecular covalent bond creation. Intermolecular dehydrogenation is also possible, and if directed properly could lead to tunable highly ordered 2D covalent structure.

*The authors aknowledge funding from NSF CHE-1446389, DOE DE-AC02-05CH11231 and NSF CHE-1904648.
12:03PM G52.00003: Electric field manipulation of the molecular spin state of a Fe(II) spin crossover complex  GUANHUA HAO (Presenter), Department of Physics and Astronomy, University of Nebraska - Lincoln, AARON MOSEY, Physics Department, Indiana University Purdue University-Indianapolis, XUANYUAN JIANG, Department of Physics and Astronomy, University of Nebraska - Lincoln, ALPHA T. N'DIAYE, Advanced Light Source, Lawrence Berkeley National Laboratory, XIN ZHANG, JIAN ZHANG, Department of Chemistry, University of Nebraska–Lincoln, RUIHUA CHENG, Physics Department, Indiana University Purdue University-Indianapolis, XIAOSHAN XU, PETER A DOWBEN, Department of Physics and Astronomy, University of Nebraska - Lincoln — The spin crossover (SCO) phenomenon, in 3d transition metal compounds, has potential applicability in molecular spintronic devices for low-cost flexible memory. Isothermal changes of the electronic structure has now been achieved for the Fe(II) spin crossover complex \([\text{Fe(H}_2\text{B(pz)}_2\text{bipy)}_2]\), where pz = tris(pyrazol-1-yl)-borohydride and bipy = 2,2'-bipyridine, by external electric fields. This isothermal voltage-controlled switching is evident in thin film bilayer structures where the molecular spin crossover film is adjacent to a molecular ferroelectric thin film (the tested examples being polyvinylidene fluoride hexafluoropropylene or croconic acid (C$_5$H$_2$O$_5$)). These organic ferroelectric substrates appear to lock the spin crossover molecular complex largely in the low or high spin state depending on the direction of ferroelectric polarization, in both a planar two terminal diode structure and for a transistor structure. Moreover, the spin state change is observed to be accompanied by a conductance change, where higher conductance occurs at a high spin state while lower conductance is observed for a low spin state, and is seen to be nonvolatile, i.e. the spins state is retained in the absence of an applied electric field.

12:15PM G52.00004: Expanding the surface chemistry synthetic toolkit: facile carbon (sp$^2$)-nitrogen(sp$^2$) bond formation on Au[111] and Ag[111]  RAYMOND BLACKWELL (Presenter), ILYA PISKUN, University of California, Berkeley, JOAQUIM SOMOZA, Max Planck Institute for the Structure and Dynamics of Matter, FANGZHOU ZHAO, STEVEN LOUIE, University of California, Berkeley, ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter, FELIX FISCHER, University of California, Berkeley — Surface assisted synthesis offers a unique pathway towards the creation of atomically precise nanostructures that cannot be achieved in solution. The Ulmann coupling—where surface stabilized radicals form covalent bonds prior to polymerization or cyclization—has emerged as a promising route for accessing novel architectures, in particular graphene nanoribbons where the electronic structure is intimately linked with the atomic structure. This reaction, however, has been limited to the formation of C-C bonds, restricting its overall scope. The ability to create novel linkages on the surface would allow for a deeper understanding of the interplay between atomic and electronic structure. Here we demonstrate facile C-N bond formation on different coinage metal surfaces at substantially lower temperatures than polymerization and subsequent C-C bond formation. Scanning tunneling microscopy and spectroscopy (STM/STS) performed conjointly with first-principles calculations confirm the desired product. The mechanism for C-N formation will be discussed along with strategies for the synthesis of extended 1-dimensional structures.
**12:27PM G52.00005: Scanning Tunneling Microscopy and Spectroscopy of Heterotriangulene-based 2D Polymers**

ZACHERY ENDERSON (Presenter), HARSHA VARDHAN MURALI, RAGHUNATH DASARI, TIMOTHY C PARKER, SETH R. MARDER, HONG LI, QINGQING DAI, SIMIL THOMAS, JEAN-LUC E BREDAS, PHILLIP N FIRST, Georgia Inst of Tech — Bottom-up synthesized covalent organic frameworks (COFs) provide a means to customize the properties of a 2D polymer from its monomer precursors. The 2D-crystalline DTPA (dimethylmethylene-bridged triphenylamine) COF is synthesized on Au(111) or Ag(111) through Ullman-type coupling. Theory predicts that the as-grown closed-shell electronic structure is semiconducting. Heating in vacuum selectively cleaves methyl groups from the monomer bridge sites, but leaves the framework intact, creating a COF resembling an ultra-flat covalent network of triangulene molecules. Enticing electronic properties are predicted, depending on the specific termination of the bridge sites. Calculations for a H-terminated case indicate that the “radical” COF will be a half-metal (fully spin-polarized density of states at the Fermi energy). Using an LT-STM, we present new information on the bridge configuration of the demethylated structure, on the electronic structure of the DTPA COF in its closed-shell (methylated) and “radical” (demethylated) forms, and on the interaction between the COF and substrate.

*Funded by the United States Army Research Office under grant number W911NF-15-1-0447 (MURI).*

**12:39PM G52.00006: Enhancement of Magnetoelectric Coupling in Ferroelectric Vinylidene Fluoride/Ferroelectric Cobalt by insertion of a dielectric layer of Magnesium Oxide.*

AASHISH SUBEDI (Presenter), KEITH D FOREMAN, SHIREEN ADENWALLA, University of Nebraska - Lincoln — Poly (vinylidene fluoride), or PVDF combines the advantages of organic based electronics with the useful bi-stable polarization characteristic of ferroelectricity. Magnetoelectric coupling between PVDF, and ferromagnetic cobalt thin films has been well established. Because VDF thin films may be deposited in vacuum, the interface between Co and VDF is clean and sharp, with little to no oxidation. We studied magnetoelectric coupling in these heterostructures, with VDF deposited directly on Co without breaking vacuum. This pristine interface resulted in very weak magnetoelectric coupling. The introduction of oxides of cobalt between these layers from exposure in air resulted in an increase in the surface coupling but presented challenges of surface purity and irreproducibility. Thus, we investigated the effect of controlled growth of a dielectric with high K, MgO. We focus on the growth and heat treatment of MgO on ferromagnetic cobalt. Consequently, we examine the interfacial interaction between the Cobalt, MgO and VDF layers and analyze how this affects the out of plane magnetic anisotropy of Cobalt.

*Research supported by NSF ECCS-1101256, MRSEC DMR-1420645 and UCARE-UNL.*
**12:51PM G52.00007: Electric Field Control of Molecular Charge State in a Single-Component 2D Organic Nanoarray**  
AGUSTIN SCHIFFRIN, DHANEESH KUMAR (Presenter), YUEFENG YIN, NIKHIL MEDHEKAR, CORNELIUS KRULL, Monash Univ — Quantum dots (QD) with an electric-field-addressable charge state are promising for digital information storage, single-electron transistors and quantum computing. Semiconductor QDs often offer limited control on size and composition, and low potential for scalability or miniaturization. Owing to their tunability and self-assembly capability, organic molecular building blocks can be used for the synthesis of two-dimensional (2D) QD arrays. Here, we report the self-assembly of 9, 10-dicyanoanthracene (DCA) molecules on Ag(111) into periodic 2D arrays, where the molecular charge state (neutral or negative) can be altered – individually and depending on the adsorption site – by the local electric field of a scanning tunneling microscope tip. Charging is enabled by an effective DCA/Ag(111) tunneling barrier and electric-field-driven electron population of the lowest unoccupied molecular orbital (LUMO). Subtle site-dependent variations of the DCA adsorption height result in a spatial modulation of the molecular polarizability, dielectric constant and LUMO energy level alignment, giving rise to a spatially dependent likelihood of charging. Our work offers potential for high-density 2D self-assembled arrays of QDs whose charge state can be addressed individually by an electric field.

**1:03PM G52.00008: Low Energy Electron Interactions with Aliphatic and Aromatic Self-assembled Monolayers on Au(111)**  
CARL VENTRICE (Presenter), SUNY Polytechnic Institute, JODI GRZESKOWIAK, University at Albany-SUNY — Electron scattering experiments have been performed on SAMs of the aliphatic molecule decanethiol and the aromatic molecule biphenylthiol grown on Au(111) via vapor phase deposition. The molecules take on either a lying down (LD) or standing up (SU) geometry, depending on coverage. From LEED, the crystal structure of both the LD phase and SU phase SAMs grown from both types of molecules is easily disrupted upon electron irradiation. Changes in peak intensities and positions of the TPD and XPS spectra indicate that the C-S bonds are cleaved for both molecules upon electron irradiation. In the SU phase of the aliphatic molecule, a large chemical shift in the C-1s and large reduction in the hydrocarbon fragments of the TPD spectra are observed. The LD phase of the aliphatic molecule and both phases of the aromatic molecule show only subtle changes to the spectra. The relative insensitivity of these SAMs to electron beam damage is attributed to charge delocalization effects. For the LD phase of the aliphatic molecule, excess charge is easily quenched since it is in direct contact with the metallic substrate. For the aromatic molecule, conjugated double bonds within the aromatic rings allow for excess charge delocalization, resulting in a lower probability for C-C bond breakage.
1:15PM G52.00009: Interface properties of FePc adsorbed on Ag (100) with and without NaCl monolayer

M. Jabrane 1,2, M.Y. El Hafidi1, M. El Hafidi1, A. Kara2

Laboratoire de la physique la matière condensée, Faculty of Sciences Ben M’Sik, Hassan II University*

MEYSOUN JABRANE (Presenter), Univ of Central Florida — For spintronic based technologies, current research focuses on developing novel nanoscale materials that combines molecular magnetism with organic spintronic devices. In this context, we studied magnetic properties of Iron-Phthalocyanine (FePc) adsorbed on various metallic surfaces. We found that FePc loses its magnetization when deposited on Cu(111) and Ag(111) with a charge transfer of 0.7e and 0.8e towards the molecule, respectively. Therefore, the interaction between FePc and the substrates affects the properties of the molecule. To circumvent the loss of FePc magnetic state, we suggest adding a monolayer of an insulator.

In this work, we tackle a full comparison of the geometric, magnetic and electronic properties of FePc/Ag(100) with and without an insulator. We have opted to use NaCl as insulator because its lattice constant is compatible to that of Ag. The calculations are performed using Density Functional Theory (DFT) and taking into account Vdw functionals to improve the description of the interactions.

1:27PM G52.00010: Electric-field assisted nucleation processes of croconic acid films*

YIFAN YUAN, XUANYUAN JIANG, SHASHI PODDAR (Presenter), XIAOSHAN XU, University of Nebraska - Lincoln — Growth of organic thin films using physical vapor deposition typically follows a three-dimensional mode, resulting in a rough surface, which undermines their application potentials. To address this issue, we have studied the effect of electric field and temperature on the growth dynamics, especially the heterogeneous nucleation process, of croconic acid (CA) films, taking advantage of the large dipole of the molecules and the ferroelectric polarization of the molecular crystals. We found that the nucleation rate has a maximum at an intermediate temperature, and the electric field shifts the maximum nucleation rate towards the lower temperature. An analysis using classical nucleation theory suggests that the electric field decreases sublimation temperature, increases the wetting angle, and decreases the surface diffusion barrier. These results provide important insight into the growth of molecular crystal films under electric fields and pave a way to fabricate films with better surface characteristics for molecular ferroelectric films.

*The authors acknowledge the support from the National Science Foundation through the Materials Research Science and Engineering Center (Grant No. DMR-1420645).
Memory devices are responsible for a significant fraction of the energy consumed in electronic systems—typically 25% in a laptop and 50% in a server station. Reducing the energy consumption of memories is an important goal. For the evolving field of artificial intelligence the compatible devices must simulate a neuron. In the organic memristors based on Ru centred phenyl azo pyridine, spin coated on oxide surfaces, the device performance exceeds the ITRS roadmap specification significantly demonstrating the viability of this system for practical applications. More than that, the redox states of the molecules can be studied in operando using Raman and UV-Vis spectroscopies leading to a clear mechanistic understanding. By enhancing the interface fields the switching energies of the devices could approach atto Joules at sub-10 nm dimension. These molecular devices are extremely stable and reproducible—significant improvement from conventional organic electronics.

How could we “see” the processes that occur in complex atomic-scale heterogeneous interfaces? It was suggested that Surface-enhanced Raman spectroscopy presents a keen approach for studying such systems, implying utilization of the Chemical Enhancement (CE). The latter is expected to report all information about the interfacial electronic coupling, however, a substantial learning curve is ahead before that information can be fully understood. The case of Graphene Enhanced Raman Spectroscopy (GERS) appears to be particularly intriguing. A delocalized electron system of graphene coupled with localized electronic states of organic adsorbates makes a significant challenge for understanding their Raman spectroscopy. We present a systematic computational study of Tetracyanoquinodimethane (TCNQ) adsorbed on graphene. This talk will report about simulations of surface-enhanced Raman spectra along with the supporting electronic structure analysis, focusing on the interfacial charge transfer and electron-phonon coupling. The application of a wide range of external electric biases allows us to modulate the charge transfer across the interface and reveal its role in corresponding changes of Raman spectra.
Comparitive STM and LEED study of the self-assembly of theobromine on Au(111) and few layer graphene on SiC(0001)*  

ISMAIL BALTACI (Presenter), MALTE SCHULTE, CARSTEN WESTPHAL, Experimental Physics, TU Dortmund University — Graphene has unique electronic and structural properties and is of interest in a broad range of applications. The functionalization of graphene by molecular adsorbates enables applications like organic sensors and solar cells. As the weak interaction between substrate and adsorbate is important, graphene and Au(111) are suitable substrates due to their low reactivity. Compounds of the xanthine group have a great effect on the human central nervous system resulting in energy arousal and increased cognitive function\textsuperscript{1,2}. Hence they are of great significance for applications in pharmacology, toxicology, and biochemistry\textsuperscript{3,4}.

Here we present the first experimental results of the xanthine derivate theobromine weakly bonded to graphene and to Au(111) at room temperature. The molecule layers are characterized utilizing STM and LEED to compare the self-assembly on Au(111) and on graphene. The molecule structures show different domains and also the existence of glide planes.

Session G53 APS: 2D Synthesis and Characterization  
Mile High Ballroom 1F - Fei Hui, Technion - Israel Institute of Technology - Tag(s): Focus

Towards room-temperature v magnetic semiconductors [Invited]  
YOUNG-HEE LEE (Presenter), IBS Center for Integrated Nanostructure Physics, Institute for Basic Science, Sungkyunkwan University — The ferromagnetic state in van der Waals two-dimensional (2D) materials has been reported recently in the monolayer limit. Intrinsic CrI\textsubscript{3} and CrGeTe\textsubscript{3} semiconductors reveal ferromagnetism but the T\textsubscript{c} is still low below 60K. In contrast, monolayer VSe\textsubscript{2} is ferromagnetic metal with T\textsubscript{c} above room temperature but incapable of controlling its carrier density. Moreover, the long-range ferromagnetic order in doped diluted chalcogenide semiconductors has not been demonstrated at room temperature. The key research target is to realize the long-range order ferromagnetism, T\textsubscript{c} over room temperature, and semiconductor with gate tunability. Here, we unambiguously observe a ferromagnetic hysteresis loop together with magnetic domains above room temperature in diluted V-doped WSe\textsubscript{2}, while maintaining the semiconducting characteristic of WSe\textsubscript{2} with a high on/off current ratio of five orders of magnitude. Some examples of other magnetic 2D materials are also presented.
Polymer-Free Transfer of 2D Materials onto III-V Semiconductor Surfaces for Scanning Probe Microscopy and Molecule-Encapsulation Experiments*  

LIHY BUCHBINDER (Presenter), Department of Physics, University of New Hampshire, SARA MUELLER, JAY A GUPTA, Department of Physics, The Ohio State University — A tabletop, dry touch-transfer method that employs van der Waals forces was used to transfer multi- to few-layer flakes of hexagonal boron nitride (hBN) and graphite onto cleaved, atomically flat GaAs (110) and InSb (110) surfaces. This method offers a cleaner alternative to current polymer-involved transfer methods, which leave polymer traces on the sample surface and require an extensive cleaning process for scanning probe microscopy (SPM) study.

An attractive application of this touch-transfer method is the encapsulation of target molecules between the semiconductor surface and graphene flakes for scanning tunneling microscopy (STM) studies. The conductivity of graphene allows us to probe the electronic states of otherwise challenging molecules and explore their possible applications. We present results of encapsulation of deionized water droplets between GaAs (110) and thinned graphite, characterized by atomic force (AFM), scanning electron (SEM), and optical microscopy techniques. Further studies will utilize nano-squeegeeing techniques using contact-mode AFM to control the placement of trapped water molecules.

*Funding for this research was provided by the Center for Emergent Materials: an NSF MRSEC under award number DMR-1420451.

Improved contacts to two-dimensional materials for extracting emergent properties  

CURT RICHTER (Presenter), Physical Measurement Laboratory, National Institute of Standards & Technology, SIYUAN ZHANG, Theiss Research and The National Institute of Standards and Technology, NICHOLAS B. GUROS, Department of Chemical and Biomolecular Engineering, University of Maryland and The National Institute of Standards and Technology, SON LE, Theiss Research and The National Institute of Standards and Technology, ARVIND BALIJEPALLI, CHRISTINA HACKER, Physical Measurement Laboratory, National Institute of Standards & Technology — It is critical to control the properties of electrical contacts to two-dimensional (2D) material systems such as twisted bilayer graphene or superconducting 2D systems in order to probe and properly extract their emergent quantum properties. We present here effective routes for contact engineering. It has been demonstrated that TMD monolayers can be effectively doped by using molecular reductants and oxidants introduced onto the surface from solution. [1] In this study, we investigated the effects of molecular doping and contact engineering on the 2D/metal interfaces and charge transport properties of MoS$_2$ devices. We show that MoS$_2$ p-type FETs can only be achieved through combining molecular doping and high-work function metals (e.g. Pd) [2]. We have demonstrated an exposed material forming gas cleaning anneal that effectively decreases deleterious organic contamination arising during fabrication as evidenced by uniform and improved field-effect transistor (FET) performance metrics [3] such as field-effect mobility and threshold voltage. [1] S. Zhang, et al., Adv. Mater. 30, 1802991 (2018); [2] S. Zhang et al., Appl. Phys. Lett. 115, 073106 (2019); [3] N. Guros, et al., ACS Appl. Mater. Interfaces. 11, 16683 (2019).
Graphene has attracted significant interest in recent years. Observation of unconventional superconductivity in twisted bilayer graphene, topological quantum phases, and observation of even denominator FQHE states are some of the exciting new findings [1]. The challenge lies in obtaining large enough single layers of graphene that can be used for device fabrication. Since graphene is sensitive to the surrounding environment, leaving the sample at ambient conditions would heighten the interactions with water and oxygen, increasing impurities and defects. Encapsulating graphene provides significant improvement to the quality of samples. Here we discuss the fabrication and characterization of graphene samples covered from h-BN prepared by mechanical exfoliation and dry transfer method. Optical microscope and AFM imaging were employed in determining the thickness of samples. We studied the transport properties of several µm scale graphene devices with a different number of layers and different geometries. Further, we examine the effect of current annealing on such devices.

12:27PM G53.00005: Metallicity of 2H-MoS$_2$ Induced by Au Hybridization*  BRANDON BLUE (Presenter), Physics and Nanoscience Technology Center, University of Central Florida, GLENN JERNIGAN, Naval Research Laboratory, DC, DUY LE, Physics and Renewable Energy and Chemical Transformations Cluster, University of Central Florida, JOSE FONSECA, Naval Research Laboratory, DC, STEPHANIE LOUGH, JESSE E THOMPSON, DARIAN SMALLEY, Physics and Nanoscience Technology Center, University of Central Florida, TALAT RAHMAN, Physics and Renewable Energy and Chemical Transformations Cluster, University of Central Florida, JEREMY ROBINSON, Naval Research Laboratory, DC, MASA ISHIGAMI, Physics and Nanoscience Technology Center, University of Central Florida — The interaction between bulk metal contacts and two-dimensional (2D) transition metal dichalcogenides (TMDs) has a critical influence on overall device performance in a variety of potential applications. This interaction has been studied extensively in the past, especially in the case of molybdemenum disulfide (MoS$_2$), with seemingly contradictory results. In this work, we directly exfoliate monolayer MoS$_2$ onto bulk Au and anneal the resulting heterostructure under ultra-high vacuum (10$^{-10}$ Torr, UHV) to 450 °C. After annealing, the MoS$_2$ monolayer is observed under scanning tunneling microscopy/spectroscopy (STM/STS) to remain in its 2H lattice configuration, yet with regions ranging from fully gapped to metallic. This observation is corroborated by ex situ Raman and photoemission spectroscopies, which show no signs of the otherwise expected 1T or 1T’ structural phase transitions. Theoretical calculations suggest the previous band-gap tuning observed in MoS$_2$-Au heterostructures is due to hybridization and chemical bonding at the S-Au interface, which can completely close the band-gap of 2H-MoS$_2$ at sufficiently short S-Au distances.

* D.L. and T.S.R. are supported in part by U.S. Department of Energy Grant DE-FG02-07ER46354.

12:39PM G53.00006: Reversible hydrostatic strain in graphene/gold nanoparticles hybrid material induced by laser irradiation*  ANDRÁS PÁLINKÁS (Presenter), Nanostructures Laboratory, Centre for Energy Research, Budapest, Hungary — Gold nanoparticles (NPs) were prepared on SiO$_2$ substrate by local annealing of gold thin films using focused laser beam. CVD-grown graphene was transferred onto the prepared NPs. Subsequent Raman-spectroscopy measurements were performed on the samples using different laser powers. We used higher laser intensity (6 mW) to locally anneal the hybrid material. Low laser powers (0.6 mW) were used to characterize the doping and the strain formed in the same areas both before and after local heating. While we found that higher intensity laser irradiation increased gradually the doping and the defect concentration in SiO$_2$-supported graphene, the same irradiation procedure did not induce such irreversible effects in the graphene supported by Au NPs. Moreover, the laser irradiation induced dynamic hydrostatic strain in the graphene on Au NPs, which turned out to be completely reversible. These results point out the role of the substrate in the resistance of graphene against laser irradiation, and can have implications in the development of graphene/plasmonic nanoparticle based high temperature sensors.

12:51PM G53.00007: Environmental effects on optoelectronic properties of heterostructures of 2D materials  ATIKUR RAHMAN (Presenter), VRINDA NARAYANAN, GOKUL M. A., TAMAGHNACHOWDHURY, Department of Physics, IISER Pune, — We have developed a simple method to fabricate large-area MoS\(_2\) monolayer devices. We will discuss the fabrication of various heterostructures using monolayer MoS\(_2\) as one of the components. Due to the 2D nature of MoS\(_2\), the coulomb screening is less effective and the electronic and optoelectronic properties of these heterostructures depend strongly on the local environment. We will discuss how various characterization methods such as low-frequency noise, dielectric and transient photoresponse can be used to get a deeper understanding of the details of the charge transport mechanism in these systems.

1:03PM G53.00008: Electronic and Optoelectronic Properties of Indium Tin Selenide (In\(_{1-x}\)Sn\(_x\)Se)*  PRASANNA PATIL (Presenter), ROBINSON KARUNANITHY, Department of Physics, Southern Illinois University Carbondale, OLLI PITKANEN, Microelectronics Research Unit, Faculty of Information Technology and Electrical Engineering, University of Oulu, SIDONG LEI, Department of Physics and Astronomy, Georgia State University, POOPALASINGAM SIVAKUMAR, Department of Physics, Southern Illinois University Carbondale, KRISZTIAN KORDAS, Microelectronics Research Unit, Faculty of Information Technology and Electrical Engineering, University of Oulu, SAIKAT TALAPATRA, Department of Physics, Southern Illinois University Carbondale — Selenide based binary- and ternary-layered compounds show exotic physical properties beneficial for developing them for future electronic & opto-electronics based applications.\(^1\) For example; few-layered Indium Selenide (InSe) has attracted attention due to presence of direct band gap and hence its impressive photo-responsive properties.\(^1\) It was also shown that ternary layered alloys such as Copper Indium Selenide (Culn\(_7\)Se\(_{11}\)) possess properties that can be harnessed for developing fast photodetectors.\(^2\) In this talk, we will report on the electronic and optoelectronic properties of few-layered Indium Tin Selenide (In\(_{1-x}\)Sn\(_x\)Se) presented. Specifically, a comparison of the key parameters associated with electronic and optoelectronic properties of In\(_{1-x}\)Sn\(_x\)Se with \(x = 0, 0.05, 0.1\) and 1 will be presented and discussed.

Dispersive Thermometry with a Graphene Josephson Junction

RAJ KATTI (Presenter), HARPREET SINGH ARORA, Caltech, OLLI SAIRA, Brookhaven National Laboratory, EWA REJ, MATTHEW MATHENY, MICHAEL ROUKES, STEVAN NADJ-PERGE, Caltech — Graphene, with its vanishing heat capacity and weak electron-phonon coupling at cryogenic temperatures, is a promising material for ultrasensitive calorimetry and single-photon detection. Here, we present dispersive thermometry measurements performed on a tunable graphene Josephson Junction (gJJ) integrated into a resonant microwave circuit. In contrast to DC detection methods that rely on the switching of the gJJ to its resistive state, this approach allows for continuous temperature readout. We will discuss device operation and show results in both the electron- and hole-doped regimes. Our results represent a step towards fast detection of low-energy photons and phonons.

*This work has been partially supported by a Gist-Caltech memorandum of understanding. S. N-P also acknowledges support from the IQIM (NSF Physics Frontiers Center).

Characterization of nonlinear screening in ionic liquid gated graphene multilayers via infrared spectroscopy

JIHO KIM, Physics, University of Seoul, MARCELO KURODA (Presenter), Physics, Auburn University, JIWON JEON, BYOUNGJU LEE, KWANGNAM YU, EUNJIP CHOI, Physics, University of Seoul — We quantify charge distributions in turbostratic few-layer graphene combining broadband infrared transmittance spectroscopy and analytical models. We show that the non-invasive experimental technique provides layer-resolved charge density profiles in regimes of interest for energy storage applications accessed using ionic-liquid gating. More importantly, we obtain unambiguous evidence of nonlinear screening of graphene which varies with thickness and charge density. Our results present good agreement with our theoretical model that accounts for the electrostatic coupling between layers and quantum capacitance of graphene. The proposed capacitor network model suggests that the effective channel capacitance increases with multilayer thickness but saturates after three layers, underscoring graphene’s qualities for ultrathin charge storage applications. Our work suggests that the combination of ionic liquid gating and infrared transmission spectroscopy may prove useful to the study of charge distributions in two-dimensional material systems.

1:39PM G53.00011: Lithium intercalation of Black Phosphorous: Ex-situ and in-situ Raman Spectroscopy Study*  
   MANTHILA RAJAPAKSE (Presenter), MD RAJIB KHAN MUSA, USMAN ONUMINYA ABU, GAMINI U SUMANASEKERA, MING YU, JACEK BOGDAN JASINSKI, Univ of Louisville — Black phosphorous is emerging as a promising two-dimensional (2D) material which can be used as a host material for many intercalants. A systematic study on Li intercalation of black phosphorous was done using both in-situ and ex-situ electrochemical cells using black phosphorous as the cathode material. Galvanostatic discharge of dedicated in-situ electrochemical cell for Raman spectroscopy were used to study time evolution of vibrational modes under lithiation. Other than the peak broadening which is a result of structural expansion, it was observed that peaks corresponding to all three atomic vibrational modes $A_{1g}$, $B_{2g}$ and $A_{2g}$ were red-shifted as a result of lithiation. Peaks $B_{2g}$ and $A_{2g}$ shifted more towards lower wavenumbers whereas peak $A_{1g}$ shifted only 50% with respect to the other two, suggesting that Li ions prefer to be intercalated in-plane, along zig-zag and armchair directions than out-of-plane direction. Additional Transmission Electron Microscopy images were used to confirm the associated structural changes and Density Functional Theory (DFT) calculations were used to build a theoretical model for the phenomena.

1:51PM G53.00012: Study of Interface States and Dielectric Permittivity of Two-dimensional Tungsten Diselenide by Impedance Measurements*  
   FIDA ALI (Presenter), YANG ZHENG, SEKHAR BABU MITTA, WON JONG YOO, Nano-science and technology, Sungkyunkwan University — The dielectric permittivity of material holds great importance for understanding the intrinsic material properties and meanwhile, it's a critical design parameter for the design of novel device structure. In this article, we studied the capacitance-voltage (C-V) and conductance-voltage (G-V) characteristics of 2-D semiconducting WSe$_2$ based metal-insulator-semiconductor-metal capacitors under varying gate voltage ($V_G$), frequency and temperature. The obtained C-V and G-V results show a strong dependence on applied $V_G$, frequency (1 kHz to 1 MHz), and temperature (78K to 300K). From frequency-dependent C-V response, we extracted interface state density ($D_{it}$) by using the high-low frequency method, where $D_{it}$ values ranging from $3.8 \times 10^{10}$ to $3.6 \times 10^{12}$ cm$^{-2}$eV$^{-1}$ in the depletion region. Furthermore, we calculated the real ($\varepsilon'$), imaginary ($\varepsilon''$) parts of the dielectric constant and loss tangent (tan$\delta$) using C-V and G-V results. The results show that the values of $\varepsilon'$, $\varepsilon''$ and tan$\delta$ decrease with increasing frequency and increase with increasing temperature.

ANDREY SUSHKO (Presenter), KRISTIAAN DE GREVE, TROND I ANDERSEN, GIOVANNI SCURI, Physics, Harvard University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, PHILIP KIM, Physics, Harvard University, HONGKUN PARK, Chemistry and Chemical Biology, Physics, Harvard University, MIKHAIL LUKIN, Physics, Harvard University — The optical and electronic properties of van der Waals (vdW) heterostructures depend strongly on the atomic stacking order of the constituent layers. This is exemplified by Mott insulator states in ABC-stacked graphene, and topologically protected states along AB/BA boundaries in bilayer graphene. Moreover, periodic variation of local atomic registry, known as moiré patterns, has given rise to superconductivity in twisted bilayer graphene and exotic exciton states in TMD heterobilayers. However, the nm-scale moiré structure is typically indirectly deduced, because the conventional imaging technique, transmission electron microscopy (TEM), requires sample preparation that is incompatible with most optical and transport measurements. We present a method to directly image the local stacking order in complete vdW devices, including hBN-encapsulation, top- and bottom- graphite gates, and standard Si-substrates. Using this method, we demonstrate imaging of reconstructed moiré patterns in stacked TMDs, ABC/ABA stacking order in graphene multilayers, and AB/BA boundaries in bilayer graphene. Furthermore, we show that optical properties of the TMD are conserved after imaging, enabling correlation of local stacking order with optical and electronic properties.

Session G54 DCMP: Fractional Quantum Hall Effect and Composite Fermions Mile High Ballroom 2A - Yaroslaw Bazaliy, Univ of South Carolina
11:15AM G54.00001: Bloch Ferromagnetism of Composite Fermions  MD. SHAFAYAT HOSSAIN (Presenter), Princeton University, TONGZHOU ZHAO, SONGYANG PU, Department of Physics, Pennsylvania State University, M A MUEED, MENG MA, KEVIN VILLEGAS ROSALES, EDWIN CHUNG, LOREN PFEIFFER, KENNETH WEST, K. W. BALDWIN, Princeton University, JAINENDRA JAIN, Department of Physics, Pennsylvania State University, MANSOUR SHAYEGAN, Princeton University — The magnetic properties of the ground state of a low-density, 2D electron system (2DES) have been a topic of intense theoretical and experimental speculation and controversy, because the physics here is governed by strong correlations. Bloch predicted a fully spin-polarized ground state for a dilute fermionic system in 1929. However, such a state has eluded experimental realization for the last nine decades. Here we present an experimental realization of the elusive interaction-driven spin polarization in a dilute, 2D fermionic system, namely composite fermions (CFs). CFs are exotic quasiparticles, each composed of an electron and two flux quanta, formed in the half-filled Landau level of a 2DES. We determine the spin-polarization of these CFs via direct measurements of the CFs’ Fermi wavevector. We find that at high electron densities ($n_e$), the CFs are fully spin-polarized, consistent with previous experiments. As we lower $n_e$, the CFs lose their magnetization, also as expected. Remarkably, however, as $n_e$ is further reduced, the CFs make a sudden transition and become fully spin-polarized. This spontaneous magnetization of CFs closely resembles the Bloch ferromagnetism. We also performed theoretical calculations that provide a semi-quantitative understanding of the phenomenon.

11:27AM G54.00002: Hall viscosity of composite fermions*  SONGYANG PU (Presenter), Pennsylvania State University, MIKAEL FREMLING, Utrecht University, JAINENDRA JAIN, Pennsylvania State University — Hall viscosity, also known as the Lorentz shear modulus, has been proposed as a topological property of a quantum Hall fluid. Using a recent formulation of the composite fermion theory on the torus [1], we evaluate the Hall viscosities for a large number of fractional quantum Hall states at filling factors of the form $\nu=n/(2pn\pm1)$ [2], where $n$ and $p$ are integers. The calculated Hall viscosities $\eta^A$ agree with the expression $\eta^A = hS\rho/8\pi$, where $\rho$ is the density and $S$ is the ‘`shift“ in the spherical geometry [3]. We show that the Hall viscosity for $\nu=n/(2pn+1)$ may be derived analytically from the microscopic wave functions providing some assumption. This derivation is applicable to a class of states in the parton construction, which are products of integer quantum Hall states with magnetic fields pointing in the same direction [4].

*S.P. and J.K.J. was supported in part by the U. S. Department of Energy, Office of Basic Energy Sciences, under Grant No. DE-SC0005042. M.F. was supported by the D-ITP consortium.
11:39AM G54.00003: Fractional Chern insulators in magic-angle twisted bilayer graphene in the Hofstadter regime*  BARTHOLOMEW ANDREWS (Presenter), ALEXEY SOLUYANOV, Univ of Zurich — We apply a perpendicular magnetic field to the minimal effective two-orbital Fermi-Hubbard model describing the low-energy physics of twisted bilayer graphene at the first magic angle. Through the use of a Peierl's substitution, we determine the Landau level splitting and study the structure of the resulting Chern sub-bands for a range of magnetic flux per plaquette. We identify the minimal examples of low-energy topological flat sub-bands in this framework. We show that, with the inclusion of a density-density interaction, fractional Chern insulator states can be realized solely within these flat bands. Specifically, we characterize the $\nu = 1/3$ Laughlin state through the use of change pumping, spectral flow, entanglement scaling, and CFT edge state counting; and we analyze its dependence on band flatness. Ultimately, we comment on the requirements for the observation of fractional Chern insulators for this system in experiment.

11:51AM G54.00004: Quantum Well Width Dependence of the Fractional Quantum Hall Energy Gaps  KEVIN VILLEGAS ROSALES (Presenter), PRANAV T MADATHIL, EDWIN CHUNG, K. W. BALDWIN, KENNETH WEST, LOREN PFEIFFER, MANSOUR SHAYEGAN, Princeton University — The fractional quantum Hall effect (FQHE) stems from the strong short-range Coulomb interaction in a two-dimensional (2D) electron system at high magnetic fields. However, the Coulomb interaction is softened in realistic samples which contain quasi-2D systems with a finite (non-zero) electron layer thickness. This softening leads to a weakening of the FQHE states, as manifested in a lowering of their energy gaps in both experiments [1] and calculations [2,3]. Here we present measurements of the energy gaps, from the temperature dependence of the magnetoresistance minima, of several fractional states in the lowest Landau level as a function of the width of the confining square quantum well. Our samples have a fixed density ($n \approx 1 \times 10^{11}$ cm$^{-2}$) while the width of the confining GaAs well varies between 20 and 80 nm. This is in contrast to measurements reported in [1] where the electrons were confined to parabolic Al$_x$Ga$_{1-x}$As quantum wells. The gaps in our measurements change in magnitude when plotted versus the GaAs well width. We contrast our results with numerical calculations that include the role of finite layer thickness [2,3].

12:03PM G54.00005: Achievement of Systematically Higher Transport Mobilities for a Large Range of Two-dimensional Electron Densities in GaAs Quantum Wells*  LOREN PFEIFFER (Presenter), EDWIN CHUNG, K. A. VILLEGAS-ROSALES, K. W. BALDWIN, KENNETH WEST, MANSOUR SHAYEGAN, Princeton University — For the range of two-dimensional (2D) electron densities between $1.5 \times 10^{10} \text{ cm}^{-2}$ and $1.4 \times 10^{11} \text{ cm}^{-2}$, we report measurements that confirm a ~60 to 70 % increase in the transport mobility of remotely-doped GaAs quantum wells compared to all previous GaAs material. A characteristic example of this development is the 2D transport mobility at an electron density of $1 \times 10^{11} \text{ cm}^{-2}$ in a 50 nm quantum well. Previously, in this type of sample the electron mobilities were limited to $\sim 1.8 \times 10^{7} \text{ cm}^{2}\text{V}^{-1}\text{s}^{-1}$; now we have grown several with transport mobilities reaching $\sim 3.0 \times 10^{7} \text{ cm}^{2}\text{V}^{-1}\text{s}^{-1}$. We attribute these results to our program of high-temperature in-situ bakes that have cleaned our AlGaAs barrier material of oxygen impurities, and to the use of large-area cryogenic cold-plates operating at 17 K in the vacuum sump of our molecular beam epitaxy chamber. When cooled to temperatures below 100 mK, the magnetotransport data of the $1 \times 10^{11} \text{ cm}^{-2}$ samples described above are remarkable, displaying clear quantum Hall features at the Landau level filling factors $\nu = 11/23, 12/25$, and even $13/27$.

12:15PM G54.00006: Renormalization Group Flow of Dirac Composite Fermions at Half Filling*  JONATHAN SAN MIGUEL (Presenter), Stanford Univ, HART GOLDMAN, Physics, University of Illinois, Urbana-Champaign, PRASHANT KUMAR, SRINIVAS RAGHU, Stanford Univ — We compare the effects of gauge field fluctuations between different composite fermion descriptions of the half-filled Landau level: the Halperin-Lee-Read (HLR) theory of non-relativistic composite fermions and the theory of Dirac composite fermions recently proposed by Son. While the Dirac theory is explicitly particle-hole symmetric, the HLR theory contains a fluctuating statistical gauge field which appears to break particle-hole symmetry. To better characterize this distinction, we present a renormalization group study of these theories in the presence of Coulomb interactions, using a controlled expansion both in the number of fermion species and the width of the Coulomb potential. In particular, we pay close attention to the effects in the HLR theory that break particle-hole symmetry. We find that both theories are described by marginal Fermi liquid fixed points and compare their universal features.

Heterostructure Design for High Two-dimensional Electron Density in GaAs/AlGaAs Quantum Wells at Large Hydrostatic Pressures

EDWIN CHUNG (Presenter), Princeton University, SHUAI YUAN, YANG LIU, Peking University, K. W. BALDWIN, KENNETH WEST, MANSOUR SHAYEGAN, LOREN PFEIFFER, Princeton University

The application of hydrostatic pressure to GaAs/AlGaAs heterostructures has been a topic of great interest due to the possibility of achieving a $g$-factor $\approx 0$ in high-quality, two-dimensional electron systems (2DESs). Despite the exciting prospect of studying electron-electron interactions in the absence of spin splitting, there are very few experimental reports on this subject. This is because in standard modulation-doped GaAs/AlGaAs heterostructures, the 2DES density decreases significantly as the magnitude of hydrostatic pressure applied to the system is increased. Here, we present a heterostructure design that circumvents such density degradation, so that high-density, high-quality 2DESs can be obtained at large hydrostatic pressures. We show that by implementing this scheme, the 2DES density only decreases by $\sim 4 \times 10^{10}$ cm$^{-2}$ even at a hydrostatic pressure of 8.2 kbar. This is a factor of $\sim 4$ improvement compared to conventional structures. We will also present low-temperature magnetotransport data that demonstrate the high quality of our samples at large hydrostatic pressures.

Diagnosis of universal geometric responses of fractional quantum Hall liquids

WEI ZHU (Presenter), Westlake University, DONNA SHENG, California State University Northridge, ZHAO LIU, Zhejiang University, LIANGDONG HU, Westlake University

Geometric response of topological quantum liquids is expected to reveal rich phenomenon. However, explicit demonstration or identification of the geometric response in a microscopic model is very challenging. Here, we demonstrate that Dehn-twist deformation is able to reveal both the universal modular properties and the microscopic features. We provide numerical evidences for various fractional quantum Hall (FQH) states, including fermionic and bosonic Laughlin states, Hierarchy states, Halperin states and Moore-Read states, by means of exact diagonalization calculations. We conclusively show, geometric transformation applied on torus geometry gives rise to a viscosity related Berry phase, which reflects the geometric metric of elementary FQH droplets. It also captures intrinsic modular information like topological spin and chiral central charge. These findings not only provide a unified description of Berry phase induced by geometric deformation, but also provide a systematical way to inspect the incompressibility of a gapped topological order in the projected Landau level.
12:51PM G54.00009: Particle-hole symmetry of the fractional quantum Hall effect in the lowest Landau level* EDUARDO PALACIOS (Presenter), MICHAEL R PETERSON, California State University, Long Beach — Electrons confined to two-dimensions experience the fractional quantum Hall effect (FQHE) at low electron densities, high magnetic fields, and low temperatures. FQHE states are topologically ordered phases characterized by the electron filling factor $\nu$ which is the electron number divided by the Landau level degeneracy. Alternatively, under particle-hole conjugation of a spin-polarized system confined to a single Landau level one can consider the system in terms of holes (the absence of an electron) with a hole filling factor of $\nu_h = 1 - \nu$. Naively, if the system maintains particle-hole symmetry, then the FQHE at filling factor $\nu$ will also occur at $1 - \nu$ with all the same properties. However, realistic effects such as Landau level mixing can break particle-hole symmetry at the level of the Hamiltonian through the inclusion of three-body terms. We study the nature of particle-hole symmetry on the FQHE in the lowest Landau level under realistic conditions numerically using exact diagonalization.

1:03PM G54.00010: Identification of topological orders in fractional quantum Hall state at $\nu=1/4$* KWOK WAI MA (Presenter), Brown University — The nature of the fractional quantum Hall state at quarter filling in a wide quantum well is still under debate. Both one-component non-Abelian and two-component Abelian orders have been proposed to describe the system. Interestingly, these candidates received support from different experiments under disparate conditions. In this article, we focus on non-Abelian orders from Cooper pairing between composite fermions and the Abelian Halperin-(5,5,3) order. We discuss and predict systematically different experimental signatures to identify them in future experiment. In particular, we address the Mach-Zehnder interferometry experiment and show that it can identify the recently proposed 22111 parton order.

*This work was supported by the National Science Foundation under Grant No. DMR-1607451
1:15PM G54.00011: Anomalous nematic states in half-filled high Landau levels*  XIAOJUN FU (Presenter), QIANHUI SHI, MICHAEL ZUDOV, University of Minnesota, GEOFF C GARDNER, JOHN WATSON, MICHAEL MANFRA, Purdue University, K. W. BALDWIN, LOREN PFEIFFER, KENNETH WEST, Princeton University — It is well established that the ground states of a two-dimensional electron gas with half-filled high (N ≥ 2) Landau levels are compressible charge-ordered states, known as quantum Hall stripe (QHS) phases. The generic features of QHSs are a maximum (minimum) in a longitudinal resistance $R_{xx}$ ($R_{yy}$) and a non-quantized Hall resistance $R_H$. This talk will report on emergent minima (maxima) in $R_{xx}$ ($R_{yy}$) and plateau-like features in $R_H$ in half-filled $N ≥ 3$ Landau levels. Remarkably, these unexpected features emerge at temperatures considerably lower than the onset temperature of QHSs, suggestive of a new ground state.

1:27PM G54.00012: Strain-induced resistance anisotropy near the FQHE v=5/2 in two-dimensional GaAs single quantum wells*  ALEXANDER STERN (Presenter), Max Planck Inst, BRIAN CASAS, Department of Physics and Astronomy, University of California Irvine, JOHANNES POLLANEN, Department of Physics and Astronomy, Michigan State University, JAMES EISENSTEIN, Department of Physics, California Institute of Technology, KENNETH WEST, LOREN PFEIFFER, Department of Electrical Engineering, Princeton University, JING XIA, Department of Physics and Astronomy, University of California Irvine — We report strain-dependent low temperature magnetotransport measurements of a two-dimensional electron gas (2DEG) confined in GaAs single quantum wells. The samples are mounted to a piezoelectric-based strain device with which we can, in situ, apply and vary tensile strain. With this apparatus, we have achieved strain as large as ~0.5% in GaAs quantum wells at cryogenic temperatures. We find that increasing strain causes the magneto-resistance of the 2DEG confined in the quantum well to become anisotropic near the filling factor $v = 5/2$. Additionally, we find that the effects of strain are highly dependent on the magnitude of the magnetic field applied. These anisotropic states are metastable and resume an isotropic state after a temperature dependent decay.

*The work at UC Irvine is supported by NSF Grant No. DMR- 1350122
Density Functional Theory of the Abelian Anyon Gas

YAYUN HU
(Presenter), Pennsylvania State University, GANPATHY MURTHY, Department of Physics and Astronomy, University of Kentucky, SUMATHI RAO, Harish-Chandra Research Institute, Homi Bhabha National Institute, JAINENDRA JAIN, Pennsylvania State University — A Kohn-Sham density functional theory of composite fermions takes into account the flux attached to composite fermions in a self-consistent fashion [1]. We extend this method to treat a system of many anyons. We construct a series of states that do not involve the center of mass excitations, and explore behavior in the vicinity of the fermionic statistics. We compare the energy obtained from our DFT calculation with exact energies known for small systems and find a qualitative and semi-quantitative agreement. Our method provides an understanding of the existing exact result and also a self-consistent way to calculate the ground state properties of the anyon gas in the thermodynamic limit.

This work is supported in part by DOE under Grant no. DE-SC0005042 and by the China Scholarship Council.

From CFT matrix product states to parent Hamiltonians

MATHEUS SCHOSSLER (Presenter), Washington University, St. Louis, SUMANTA BANDYOPADHYAY, Stockholm University/Nordita, ALEXANDER SEIDEL, Washington University, St. Louis — We study frustration free (FF) Hamiltonians of fractional quantum Hall (FQH) states from the point of view of the Matrix-product-state (MPS) representation of their ground/excited states. There is a wealth of solvable models relating to FQH physics, which, however, is mostly derived and analyzed from vantage point of first quantized "analytic clustering properties". In contrast, one obtains long-ranged FF lattice models when these Hamiltonians are studied in an orbital basis, which is the natural basis for the MPS representation of FQH state that has been of much interest lately. The connection between MPS-like states and frustration free parent Hamiltonians is central guiding principle in the construction of solvable lattice models, but thus far, only for short range Hamiltonians and MPS of finite bond dimension. The situation in the FQH context is fundamentally different. Here we expose the direct link between the infinite-bond-dimension MPS structure of Laughlin and Moore-Read-type CFT states and their parent Hamiltonians. Possible uses for states that lack a representation with nice analytic clustering properties are discussed.

**G54.00015: Manifestations of the Uniform Berry Curvature in the Physics of Composite Fermions**

GUANGYUE JI (Presenter), JUNREN SHI, Peking University — It was proposed that the composite fermion is subject to a uniform Berry curvature in the momentum space [1]. Based on the picture, we theoretically consider a number of possible manifestations of the uniform Berry curvature. We show that the presence of the Berry curvature induces a shift in the commensurability condition of the geometrical resonance experiments. We argue that the shift had actually been observed in experiments. We further show that an electrostatic modulation, which is equivalent to a modulation of the Chern-Simons field of composite fermions, and the modulation of an externally applied magnetic field, yield different commensurability conditions. Moreover, we determine the low-frequency and long wavelength electromagnetic responses of a composite fermion system, and find results different from both the Halperin-Lee-Read theory and Son's Dirac theory.

**Session G55 DCMP: Transport and thermodynamic properties of topological systems: I** Mile High Ballroom 2B

**11:15AM G55.00001: Evidence of topological gap opening in the surface state of Bi$_2$Se$_3$ by proximity to a magnetic insulator**

SATYAKI SASMAL (Presenter), MATHIMALAR S, RAJASEKHAR P, ARCHIT BHARDWAJ, SAURABH CHAUDHARY, Tata Institute of Fundamental Research, Centre for Interdisciplinary Sciences, Hyderabad, BISWARUP SATPATI, Saha Institute of Nuclear Physics, KARTHIK RANAN, Tata Institute of Fundamental Research, Centre for Interdisciplinary Sciences, Hyderabad — Out-of-plane magnetism at the Bi$_2$Se$_3$/EuS interface is experimentally demonstrated and theoretically proposed [1,2,3], that is expected to break time-reversal-symmetry of topologically protected surface states (SSs). However, an exchange gap (EG) opening at the Dirac point due to proximity effect of the magnetic insulator (MI), EuS, is not observed before using transport studies, primarily due to dominant bulk conduction over the SSs. By using bottom gate voltage and external magnetic field studies, we report evidence of a metal-to-insulator transition at Bi$_2$Se$_3$/EuS interface, attributed to the opening of EG, with the signature of half-integer quantum Hall effect when Fermi level is tuned into the EG [4]. Our study also shows a gate-controlled enhanced interface magnetism at Bi$_2$Se$_3$/EuS interface which we attribute to the conduction carrier-mediated RKKY interactions [3]. Our efforts in this direction with suitable MI/TI/MI device will possibly allow us to demonstrate a switchable topological electronic device using magnetic proximity effect studies.

*We thank TIFR-Hyderabad, SERB, DAE and ECR grant.*
Evidence for a conducting surface state in FeSi

YUHANG DENG (Presenter), YUANKAN FANG, SHENG RAN, University of California, San Diego, WEIWEI XIE, Louisiana State University, SHEN WANG, SHIRLEY MENG, CHRISTIAN T WOLOWIEC, IVAN SCHULLER, University of California, San Diego, HONGBO LOU, SHUBIN LI, QIAOSHI ZENG, Center for High Pressure Science & Technology Advanced Research, JOHN SINGLETON, Los Alamos National Laboratory, ALEXANDER BREINDEL, M BRIAN MAPLE, University of California, San Diego — Electrical transport measurements on high quality single crystals of FeSi show a crossover from semiconducting to metallic behavior at 19 K ($T_c$). This metallic temperature dependent resistivity points to a conducting surface ground state of FeSi, supported by the impact of surface-to-volume ratio on the resistivity of the sample, and the absence of features in specific heat at low temperature [1]. We further explore this surface state using high field magnetoresistance, high pressure, and magnetic field modulated microwave spectroscopy (MFMMMS). Surprisingly, the surface sensitive MFMMMS measurement of FeSi shows an anomaly near $T_c$ with a signature typically associated with superconducting transitions. Based on the similarities in magnetoresistance between FeSi and the possible topological Kondo insulator SmB$_6$, FeSi could be a possible topological insulator.

Magnetotransport and weak anti-localization signatures in band-engineered 3D topological insulator pn-heterostructures

THOMAS MAYER (Presenter), HEDWIG WERNER, FLORIAN SCHMID, JOHANNES ZIEGLER, ELISABETH RICHTER, RALF FISCHER, University of Regensburg, REBECA DIAZ-PARDO, TU Munich, JUN FUJII, IVANA VOBOJNIK, Elettra-Sincrotrone Trieste, DIETER KARL WEISS, University of Regensburg, CHRISTIAN BACK, TU Munich, MATTHIAS KRONSEDER, DOMINIQUE BOUGEARD, University of Regensburg — To experimentally harness the novel physics arising from topological surface states (TSS) in 3D topological insulators (3D TIs) it is crucial to develop control over key band structure parameters. At the same time, controlling the contribution of bulk bands to transport has represented a major experimental challenge.

In this contribution, we combine band structure engineering in Bi-based heterostructures with alloy composition-tuning to provide experimental access to single TSS. In a vertical pn-heterostructure of 3D TIs, intrinsic band bending is introduced to create an internal depletion zone. It will not only induce compensation of unintentional charges, but also lead to an isolation of the top TSS from parasitic bulk background. We present pn-heterostructures with \((\text{Bi}_{1-x}\text{Sb}_x)_2(\text{Te}_{1-y}\text{Se}_y)_3\) as the p-type layer. Varying \((x,y)\) provides extensive control over the position of the Dirac point and the Fermi level. Moreover we observe a significant reduction of bulk carriers, compared to e.g. \(\text{Bi}_2\text{Se}_3\). We analyze our heterostructures in magnetotransport and angle-resolved photoemission spectroscopy (ARPES). Furthermore we discuss our conclusions in the light of the Hikami-Larkin-Nagaoka theory for weak anti-localization signatures observed in the longitudinal magneto-resistance.

Weak Antilocalization and Anisotropic Magnetoresistance in Topological Bi\(_2\)Te\(_x\)Se\(_{3-x}\) Thin Films

GREGORY STEPHEN (Presenter), Laboratory for Physical Sciences, OWEN VAIL, Army Research Lab, JIWEI LU, University of Virginia, PATRICK TAYLOR, Army Research Lab, ADAM FRIEDMAN, Laboratory for Physical Sciences — Topological materials, such as the quintessential topological insulators in the Bi\(_2\)X\(_3\) family \((X = O, S, Se, Te)\), are extremely promising for beyond Moore’s Law computing applications where alternative state variables and energy efficiency are prized. It is essential to understand how the topological nature of these materials changes with growth conditions and, more specifically, chalcogen content. In this study, we investigate the evolution of the magnetoresistance of \(\text{Bi}_2\text{Se}_{3-x}\text{Te}_x\) for varying chalcogen ratios as a function of both temperature and angle of applied field. Weak antilocalization (WAL), an indicator of topological surface states, is observed to weaken with Te substitution. We also demonstrate that the anisotropy of the WAL follows the Tkachov-Hankiewicz model of magnetoconductance in topological insulators rather than a more trivial \(\sin\theta\) dependence. This model, which is a generalization of the Hikami-Larkin-Nagaoka model, allows for measurement of both coherence length and skin depth of the conducting surface states. These results show the surface states in \(\text{Bi}_2\text{Se}_3\) to be most isolated from the bulk states, with quality degrading through Te substitution.
12:03PM G55.00005: Quantum Oscillations in Topological Insulator β-Ag2Te with High Mobility*  PENGLIANG LENG, XIAOYI XIE (Presenter), FAXIAN XIU, Physics, Fudan University — Stimulated by the fascinating properties discovered in topological insulators, topological quantum materials have become an exciting frontier in condensed matter physics and materials science. In this study, we claim a developed growth scheme to synthesize single crystalline (β-Ag$_2$Te) nanoplates with tunable Fermi levels by chemical vapor deposition (CVD). We systematically studied the transport measurement, showing that the atomic ratio of Ag and Te can significantly change the Fermi level of Ag$_2$Te nanoplates which achieves highest reported mobility ($\sim$50000 cm$^2$/V*s), and significant quantum oscillations appear. By analyzing the frequency and amplitude of the quantum oscillation, we can obtain various parameters in Ag$_2$Te, and push back the energy band structure.

12:15PM G55.00006: Anomalous quantum oscillations in topological insulators  AREG GHAZARYAN (Presenter), Institute of Science and Technology Austria, EMILIAN NICA, ONUR ERTEN, Department of Physics, Arizona State University, POUYAN GHAEMI, Department of Physics, City College of the City University of New York — Quantum oscillations are routinely used to determine the Fermi surface (FS) in metallic systems. In topological insulators, quantum oscillations can originate from the FS of the edge states. We analyze such quantum oscillations when the chemical potential lies close to the edge of either bulk conduction or valence bands. We compare and contrast these with standard cases for edge states with 2D electron-gas and Dirac dispersions, respectively. We discuss candidate systems where deviations from the standard cases are expected to occur. We comment on the possible implications for quantum oscillations observed in topological Kondo insulators.
**12:27PM G55.00007: Detection of hole pockets in type-II Weyl semimetal MoTe$_2$ from Shubnikov-de Haas quantum oscillations**

YAJIAN HU, Department of Physics, The Chinese University of Hong Kong, WING YU, Department of Physics, City University of Hong Kong, KWING LAI, Department of Physics, The Chinese University of Hong Kong, DAN SUN, FEDOR BALAKIREV, National High Magnetic Field Laboratory, Los Alamos National Laboratory, KING YAU YIP, WEI ZHANG, ESTEBAN I PAREDES AULESTIA, Department of Physics, The Chinese University of Hong Kong, RAJVEER JHA, RYUJI HIGASHINAKA, TATSUMA D. MATSUDA, Department of Physics, Tokyo Metropolitan University, YOICHI YANASE, Department of Physics, Kyoto University, YUJI AOKI, Department of Physics, Tokyo Metropolitan University, SWEE GOH (Presenter), Department of Physics, The Chinese University of Hong Kong — The bulk electronic structure of T$_d$-MoTe$_2$ features large hole Fermi pockets at the Brillouin zone center (Γ) and two electron Fermi surfaces along the Γ-X direction. However, the large hole pockets, whose existence has important implications for the Weyl physics of T$_d$-MoTe$_2$, had never been conclusively detected in quantum oscillations. In this presentation, we report an unambiguous detection of these elusive hole pockets via Shubnikov-de Haas (SdH) quantum oscillations. At ambient pressure, the quantum oscillation frequencies for these pockets are 988 T and 1513 T, when the magnetic field is applied along the c-axis. The quasiparticle effective masses $m^*$ associated with these frequencies are 1.50 $m_e$ and 2.77 $m_e$, respectively, indicating the importance of Coulomb interactions in this system. We further measure the SdH oscillations under pressure. At 13 kbar, we detected a peak at 1798~T with $m^* = 2.86$ m$_e$. Relative to the oscillation data at a lower pressure, the amplitude of this peak experienced an enhancement, which can be attributed to the reduced curvature of the hole pockets under pressure. Combining with DFT + $U$ calculations, our data shed light on why these important hole pockets had not been detected until now.

**12:39PM G55.00008: Magnetothermoelectricity of topological semiconductor ZrTe$_5$**

JUNBO ZHU (Presenter), CHANGMIN LEE, TAKEHITO SUZUKI, Massachusetts Institute of Technology MIT, SHIANG FANG, Harvard, NUH GEDIK, JOSEPH G CHECKELSKY, Massachusetts Institute of Technology MIT — We report a comprehensive study of electric, thermoelectric, thermodynamic measurements and angle resolved photoemission spectroscopy (ARPES) of the topological insulator candidate ZrTe$_5$. The single crystals grown by a chemical vapor transport method exhibit transport properties characterized by the electronic band structure with a small band gap that is observed by ARPES. The thermoelectricity has a significant response to magnetic field exceeding 300%, for which we discuss the mechanism along with the unique properties of bands deduced from the fermiology.
12:51PM G55.00009: Resonant and Magnetic Doping in Topological Insulator Bi$_2$Se$_3$*

BRANDI WOOTEN (Presenter), Ohio State Univ - Columbus, PATRICK TAYLOR, US Army Research Laboratory, JOSEPH P C HEREMANS, Ohio State Univ - Columbus — Topological insulators (TI) are bulk insulators with topologically protected, electrically conducting surface states. Unfortunately, “practical” topological protection is observed rarely. Interactions between bulk and surface electrons result in surface electrons having short lifetimes and experiencing strong dephasing that impedes possible applications, e.g., in quantum computing. We exploit resonant doping to reduce the bulk carrier concentration to meet the Mott criterion for the metal-insulator transition: the number of electrons due to unintentional doping, $n_D$, must be less than the critical carrier concentration, $n_c$. Se vacancies make Bi$_2$Se$_3$ heavily n-type, and the Mott criterion is not reached. By adding resonant dopant Sn to Bi$_2$Se$_3$, the density of states is widened at the top of the valence band, decreasing $n_c$ by an order of magnitude, allowing for the Mott criterion to be satisfied. Seebeck measurements show a sign change for Sn-doped Bi$_2$Se$_3$ as temperature is reduced, hinting that this approach works. Further, we plan to add magnetic dopant, Mn, and perform in-field transport measurements.

1:03PM G55.00010: Identification of massive and topological surface states in the 3D topological insulator tensile strained HgTe

VALENTIN L. MÜLLER (Presenter), DAVID MAHLER, LUKAS LUNCZER, JONAS WIEDENMANN, WOUTER BEUGELING, HARTMUT BUHMANN, LAURENS W MOLENKAMP, University of Wurzburg — Topological surface states (TSS) with their linear dispersion and spin momentum locking constitute an interesting playground for basic research and future applications and have been identified in the topological insulator tensilely strained HgTe by magnetotransport measurements [1]. While the TSS are created due to the inversion of the bulk bands, additional surface states of different origin have been reported in gated devices of the topological insulator and the Dirac semi-metal phase of HgTe [2, 3]. These additional surface states are formed due to the shape of the electrochemical potential introduced by the electric field of the gate and are of general interest, since they can also be present in other topological materials. They are called massive Volkov-Pankratov states (VPS) after their first report in Ref. [4]. Here we present the unambiguous identification and manipulation of the different surface states, namely the TSS and the massive VPS, in the topological insulator HgTe by means of magnetotransport using top- and backgated devices as well as modulation doping.

1:15PM G55.00011: Transport evidence of Dirac dispersion in PbBi$_2$Te$_4$ 3D topological insulator* PRIYANATH MAL (Presenter), GANESH BERA, DEPARTMENT OF PURE AND APPLIED PHYSICS, GURU GHASIDAS VISHWAVIDYALAYA, KONI, Guru Ghasidas Vishwavidyalaya, BIPUL DAS, DEPARTMENT OF PHYSICS, National Changua University of Education, ARCHANA LAKHANI, UGC-DAE CSR Indore, G. R. TURPU, DEPARTMENT OF PURE AND APPLIED PHYSICS, GURU GHASIDAS VISHWAVIDYALAYA, KONI, Guru Ghasidas Vishwavidyalaya, C. V. TOMY, DEPARTMENT OF PHYSICS, IIT BOMBAY, PRADIP DAS, DEPARTMENT OF PURE AND APPLIED PHYSICS, GURU GHASIDAS VISHWAVIDYALAYA, KONI, Guru Ghasidas Vishwavidyalaya — The non-trivial nature of the surface states in PbBi$_{2-x}$Fe$_x$Te$_4$ is evident from the observations of the Shubnikov-de Haas (SdH) oscillations with π berry phase. Lower effective mass obtained from the Lifshitz-Kosevich fit and higher mobility values determined from the Dingle analysis confirmed the surface origin of the oscillations. An elongated band outside the surface Fermi surface is identified for pure sample and is absent for doped specimens. Combined SdH oscillations and Hall effect studies reveal the shifting of the Fermi level of PbBi$_2$Te$_4$ towards the Dirac point with successive Fe doping. Progressive decrease of the Fermi wave vector (k) and corresponding Fermi energy (E) with Fe doping can be fitted well with straight line, reveals the linear nature of the E-k diagram i.e. Dirac dispersion of topological surface states in PbBi$_2$Te$_4$. The observed weak anti-localization corroborates the spin-momentum locking as the consequence of π Berry phase acquires by the spin upon moving round the Dirac point and is consistent with SdH oscillations.

1:27PM G55.00012: Theory of drude-like nonlinear thermoelectric responses in quantum many-body systems XU YANG (Presenter), YING RAN, Boston College — A well-defined Drude peak in the linear electrical response is a fundamental feature of good metals, which has served as a basic probe of quantum materials irrespective of whether correlation is strong or not. We theoretically investigate Drude-like physics in general second-order nonlinear thermoelectric responses in time-reversal invariant noncentrosymmetric quantum many-body systems. The physical interpretations of the corresponding Drude weights are clarified, and the Drude relaxation time is discussed in the framework of the memory matrix technique. In particular, in linear responses the Drude weight is known to be related to the adiabatic derivative of the current with respect to twisted boundary conditions; while in the nonlinear case we find that the Drude weights are related to the adiabatic derivatives of dissipationless linear responses. In addition, we prove a general nonlinear reciprocal relation, and discuss nonlinear generalizations of the Lorentz ratio. Our results generalize the nonlinear Hall effect pointed out by Sodemann and Fu, and hold irrespective of whether quasiparticle descriptions are valid at low energies or not, indicating that nonlinear thermoelectric responses can serve as additional probes of strongly correlated systems such as non-Fermi liquids.
1:39PM G55.00013: Universal transport signatures of the topological phase transition in Majorana wires* AARON CHEW (Presenter), Caltech, WENYU HE, Hong Kong University of Science and Technology, JASON F. ALICEA, Caltech — Detecting the predicted magnetic-field-driven topological phase transition in proximitized nanowires is a key problem in the ongoing quest for unambiguous signatures of Majorana zero modes. We investigate the transport properties of a junction between a Luttinger liquid lead and a proximitized nanowire held at the topological phase transition. Upon fine-tuning a single parameter at the interface, the junction can realize a novel nontrivial fixed point at which electrons in the lead split into two propagating Majorana fermions, one that perfectly transmits into the critical nanowire and one that reflects. We introduce a bosonized framework for this fixed point and extract universal conductance signatures of the topological phase transition. We also comment on applications to tunneling into the edge of a two-dimensional topological superconductor.

1:51PM G55.00014: Anomalous magnetotransport at a two-dimensional correlated electron system EDOUARD LESNE (Presenter), YILDIZ SAGLAM, THIERRY VAN THIEL, Delft University of Technology, PIERRE BRUNEE, Paris-Saclay University, ANA MONTEIRO, GARY STEELE, Delft University of Technology, MARC GABAY, Paris-Saclay University, ANDREA CAVIGLIA, Delft University of Technology — The emergent two-dimensional electron system (2DES) formed at the interface between LaAlO\textsubscript{3} (LAO) and SrTiO\textsubscript{3} (STO) insulating oxides has been a subject of great interest in condensed matter physics over the last decade. Recently, the (111)-oriented STO based 2DES has attracted further attention due to its sixfold orbital and lattice symmetry whereby two consecutive planes form a dense honeycomb lattice of Ti 3\textit{d} orbitals, a host candidate for prospective topologically non-trivial electronic phases. Furthermore, we have demonstrated that the (111)-LAO/STO interface exhibits an electronic correlation driven reconstruction of its band structure, and a two-dimensional superconducting groundstate, both tunable by electrostatic field-effect.

In this work, we report on the magnetotransport properties of the 2DES in both in-plane and out-of-plane magnetic field. In the planar Hall effect configuration we observe strongly gate-dependent large non-saturating magnetoresistive signal, with further plateau structures, when the sourced current is parallel to the applied external magnetic field. We tentatively relate the observed anomalous electronic transport to the complex band structure of the (111)-LAO/STO 2DES, exhibiting a number of avoided $d_{xz}$-$d_{yz}$-$d_{xy}$ band crossings, sources of Berry phase.
2:03PM G55.00015: Resistively detected nuclear magnetic resonance in topological insulators* ZEKUN ZHUANG (Presenter), VESNA F MITROVIC, JOHN BRADLEY MARSTON, Brown University — Topological insulators (TI) possess helical edge or surface states that are protected by both time-reversal symmetry and topology. We will present our proposal to use resistively detected nuclear magnetic resonance (RDNMR) to characterize Dirac fermions at the edge or surface of the TI. The effects of nuclear spins on the edge state conductance in both 2-D and 3-D TIs will be presented.

*We acknowledge Grant NSF OIA-192199.

Tuesday, March 3, 2020 11:15 AM - 2:15 PM

Session G56 DCMP: Strange Metals Mile High Ballroom 2C - Yu He

11:15AM G56.00001: Coexisting Strange Metal and Fermi Liquid Collective Excitations in Sr$_2$RuO$_4$* ALI HUSAIN (Presenter), MATTEO MITRANO, MELINDA S RAK, SAMANTHA RUBECK, University of Illinois at Urbana-Champaign, HONGBIN YANG, Department of Chemistry and Chemical Biology, Rutgers University, FUMIHIKO NAKAMURA, Department of Education and Creation Engineering, Kurume Institute of Technology, CHANCHAL SOW, YOSHITERU MAENO, Department of Physics, Graduate School of Science, Kyoto University, PHILIP EDWARD BATSON, Department of Physics and Astronomy, Rutgers University, PETER MICHAEL AbbAMONTE, University of Illinois at Urbana-Champaign — The strange metal is an enigmatic phase found in numerous strongly correlated systems distinguished by violations of Fermi liquid and Boltzmann transport theories. Using momentum-resolved EELS (M-EELS), we previously showed that, while charge excitations of a Fermi liquid are known to propagate as plasmons with well-defined energy and momentum, the strange metal Bi$_{2.1}$Sr$_{1.9}$CaCu$_2$O$_{8+x}$ (Bi-2212) exhibits a featureless continuum of non-propagating charge fluctuations exhibiting simple scaling laws. Here, we present M-EELS results on Sr$_2$RuO$_4$ showing that it exhibits both a strange metal continuum and a well-defined low-energy collective mode below 100 meV propagating at near the Fermi velocity. Strikingly, the dispersion of this mode is strongly renormalized at low temperature where transport measurements indicate the onset of Fermi liquid behavior. These results suggest that Sr$_2$RuO$_4$ exhibits a crossover between Fermi liquid-like behavior at low energy and strange metal behavior at high energy, with the two sectors in coexistence. We also present new transmission M-EELS experiments validating the bulk origin of these observations.

11:27AM G56.00002: Classical Glasses, Black Holes, and Strange Quantum Liquids* DAVIDE FACOETTI (Presenter), GIULIO BIROLI, JORGE KURCHAN, Ecole Normale Superieure, DAVID REICHMAN, Columbia University — From the dynamics of a broad class of classical mean-field glass models we construct a quantum model with finite zero-temperature entropy, a quantum transition at zero temperature, and a time-reparametrization (quasi-)invariance in the dynamical equations for correlations. The low eigenvalue spectrum of the resulting quantum model is directly related to the structure and exploration of metastable states in the landscape of the original classical glass model. This mapping reveals deep connections between classical glasses and the properties of SYK-like models.

11:39AM G56.00003: A hydrodynamical description for transport in the strange metal phase of cuprates ANDREA AMORETTI (Presenter), Univ of Genova — High temperature superconductors are strongly coupled systems which present a complicated phase diagram with many intertwined phases appearing at the same time. This makes it difficult to understand the mechanism which generates their singular transport properties (see e.g. [1]). Hydrodynamics, which mostly relies on the symmetries of the system without referring to any specific microscopic mechanism, constitutes a promising framework to analyze these materials.

In this talk I will show that in the strange metal phase of the cuprates, a whole set of transport coefficients are described by a universal hydrodynamic framework once one accounts for the effects of quantum critical charge density waves. I will compare the theoretical prediction with the measured DC transport properties of Bi-2201 close to optimal doping, proving the validity of our approach. Our argument can be used as a consistency check to understand the universality class governing the behavior of cuprate high temperature superconductors.

11:51AM G56.00004: Strange metallic magnetotransport in electron-doped cuprates*
NICHOLAS PONIATOWSKI (Presenter), TARAPADA SARKAR, PAMPA R MANDAL SARKAR, RICHARD GREENE, University of Maryland, College Park — The infamous linear-in-T resistivity seen in hole-doped cuprates has become the hallmark of strange metallicity, but a more expansive strange metal phenomenology exists in the electron-doped compounds. Linear-in-T resistivity and linear-in-H magnetoresistivity are observed at low temperatures, in stark contrast to conventional Fermi-liquid behavior, and at high temperatures an anomalous $T^2$ resistivity is observed. In this talk, we discuss other signatures of strange metallicity at higher temperatures (50-300 K) in these compounds as evidenced by magnetotransport experiments.

12:03PM G56.00005: Ubiquitous power law behaviour in the self energy of Strange Metals*
STEEF SMIT (Presenter), Univ of Amsterdam — The high temperature superconducting state in cuprates is born out of the strange metal phase, showing resistivity linear in temperature, contravening Fermi liquid theory for metals. Theoretical understanding of this phase is limited, despite decades of research. Recently, the Anti-de Sitter/Conformal Field Theory (AdS/CFT) approach has been proposed to hold the answer, something we set out to test. ARPES experiments are able to determine the normal state electron lifetime (described by a self-energy) in a k-resolved manner. In a 2015 arXiv post (1), laser-ARPES data from BSCCO-2212 proposed that the E- and T-dependence of the self-energy are power-laws. This got the AdS/CFT community excited, as this behaviour comes out of their calculations. We have carried out analogous ARPES experiments on clean, single-layer BSCO-2201 systems over a wider range of T and E, obtaining some of the highest quality data ever recorded on these materials. This work presents the accurately extracted self-energies vs. energy and temperature, and often made assumptions such as k-independent self-energies are discussed. (1) Reber et al, arXiv (2015)

12:15PM G56.00006: Microscopic origin of the `strange' metal* KYUNGMIN LEE (Presenter), Natl High Magnetic Field Lab, AAVISHKAR PATEL, University of California, Berkeley, NANDINI TRIVEDI, The Ohio State University, SUBIR SACHDEV, Harvard University — We study a disordered Anderson-Hubbard lattice model of strongly interacting fermions. We obtain the space and time dependent electron Green’s function by numerically summing the `melon’ diagrams. We show the emergence of two `fluids’: (i) a fraction of sites, with weaker hopping than the background, hybridize with a constellation of neighboring sites and nucleate islands, and behave similar to the Sachdev-Ye-Kitaev model; (ii) the remaining background electrons scatter off SYK islands, and display strange metal transport with a linear-in-temperature resistivity, and singular spectral widths down to zero temperature with no coherence scale.

12:27PM G56.00007: Incoherent Strange Metal Sharply Bounded by a Critical Doping in Bi2212* SU-DI CHEN (Presenter), Stanford Univ, MAKOTO HASHIMOTO, SLAC National Accelerator Laboratory, YU HE, Stanford Univ, DONGJOON SONG, National Institute of Advanced Industrial Science and Technology, Japan, KEJUN XU, JUNFENG HE, THOMAS DEVEREAUX, Stanford Univ, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology, Japan, DONGHUI LU, SLAC National Accelerator Laboratory, JAN ZAANEN, Leiden University, the Netherlands, ZHIXUN SHEN, Stanford Univ — In normal metals, macroscopic properties are understood using the concept of quasiparticles. In the cuprate high-temperature superconductors, the metallic state above the highest Tc is found to be very different and called the “strange metal”. To study this state, we use angle-resolved photoemission spectroscopy to directly measure its spectral function. With increasing doping across a temperature-independent critical value pc ~ 0.19, we observe a dramatic change near the Brillouin zone boundary where the strange metal characterized by incoherent spectral function abruptly reconstructs into a more conventional metal with quasiparticle-like excitations. This sharp reconstruction signals the incoherent strange metal as a distinct state of matter. Furthermore, above the temperature scale of superconducting fluctuations, we find that the pseudogap — the anomalous suppression of low-energy spectral intensity with decreasing temperature — also sharply collapses at the very same pc. This suggests that the pseudogap is a low-temperature phenomenon associated with the incoherent strange metal.

The optical conductivity of (K,Rb,Cs)Fe$_2$As$_2$: hidden temperature behaviors and electronic correlations strength  
RICARDO LOBO (Presenter), ESPCI Paris - PSL, CNRS, Sorbonne University — We measured the temperature dependence of the optical reflectivity in undoped XFe$_2$As$_2$ iron pnictides, where X = K, Rb, and Cs. A two-Drude analysis of the data quantitatively describes the Kramers-Kronig obtained optical conductivity of all compositions. From this analysis, we extracted the scattering rate and effective mass for each Drude contribution. Both our parameters and the overall optical conductivity are compared to first principles DMFT calculations. We discuss the temperature behavior of the scattering rate as a function of X and show that a hidden linear behavior emerges from the decomposition of the optical conductivity. The comparison of the full optical conductivity to DMFT calculations allows us to infer the evolution of the electronic correlations strength with ionic replacement. Collaborators: L. de' Medici, (ESPCI Paris, France), F. Hardy, A.A. Haghighirad (Karlsruhe Institute of Technology, Germany)

12:51PM G56.00009: $^{13}$C NMR measurement of $\theta$-(BEDT-TTF)$_2$I$_3$ in non-Fermi liquid region  
KAZUYA MIYAGAWA (Presenter), HIDEAKI MURASE, TAKURO SATO, Univ of Tokyo, MASAFUMI TAMURA, Tokyo University of Science, KAZUSHI KANODA, Univ of Tokyo — The BEDT-TTF salts with $\theta$-type molecular arrangement, $\theta$-(BEDT-TTF)$_2$X, which have a triangular lattice show a wide variety of electronic states (charge order insulator, charge glass state, metal) according to monovalent anion, X. Among them, the X=I$_3$ salt is considered to be in a typical metal because quantum oscillations are observed at low temperatures [1]. On the other hand, in the optical spectrum, normal Drude response was not observed above 100 K. So the salt is different from a simple Fermi liquid picture at high temperature [2]. Recently, we report increase of resistance noise near 50 K-180 K, where the resistance exceeds the Mott limit [2,3]. In this study, the $^{13}$C NMR spectra and the 1/$T_2$, which captures slow fluctuations in the order of kHz were measured. In the salt showing charged glass, the 1/$T_2$ has a peak, which is thought to be associated with the glass formation process [4]. On the other hand, in X=I$_3$ salt, the temperature dependence of 1/$T_2$ is very weak and the absolute value remained small. There was also no significant increase in linewidth. This means that the spectral density of fluctuation in the kHz range is small. [1] M. Tamura et al., JPSJ (1994). [2] K. Takenaka et al., PRL (2005). [3] T. Sato et al., Nat. Mat. (2019). [4] K. Miyagawa et al., JPSJ (2019).
Machine learning of non-Fermi liquid transport in quantum critical metals

GEORGE DRISCELL (Presenter), Cornell University, SAMUEL LEDERER, CARSTEN BAUER, SIMON TREBST, University of Cologne, EUN-AH KIM, Cornell University — Anomalous transport, such as T-linear resistivity (a hallmark of non-Fermi liquid behavior), is a ubiquitous feature of strongly correlated metallic systems, but famously difficult to understand theoretically. For relevant simple models, the transport computations of even numerically exact Monte Carlo simulations are subject to enormous systematic errors and come at great additional computational cost. Building on earlier work, we apply quantum loop topography (QLT) and supervised learning on quantum Monte Carlo data to examine the Fermi liquid to non-Fermi liquid crossover in models of both Ising nematic and spin density wave quantum criticality. Previous work on these models has demonstrated this crossover using measurements of correlation functions at nonzero imaginary time separation. Our results, using only equal time measurements, show good agreement with these previous results at dramatically lower computational cost. Hence, QLT-based machine learning can accelerate the exploration of parameter space in search for non-Fermi liquid behavior by obviating the need for expensive dynamical measurements.

Normal state properties of quantum-critical metals at finite temperatures

AVRAHAM KLEIN (Presenter), University of Minnesota, YONI SCHATTNER, Stanford University, EREZ BERG, Weizmann Institute of Science, ANDREY CHUBUKOV, University of Minnesota — Recent years have seen an intense effort to study models of fermionic quantum criticality and superconductivity via sign-problem-free quantum Monte Carlo. These studies found a number of puzzling features, which are in qualitative disagreement with quantum-critical-scaling theories and, in particular, cast doubt on the validity of Eliashberg-type approaches to quantum criticality. I will discuss how thermal fluctuations destroy the nice scaling properties of quantum-critical systems and show that after generalizing Eliashberg theory to account for thermal fluctuations many of the qualitative disagreements vanish. This work provides concrete guidelines for analyzing ongoing numerical work.

Supermetal

HIROKI ISOBE (Presenter), LIANG FU, Massachusetts Institute of Technology MIT — We study the effect of electron interaction in an electronic system with a high-order Van Hove singularity, where the density of states shows a power-law divergence. Owing to scale invariance, we perform a renormalization group (RG) analysis to find a nontrivial metallic behavior where various divergent susceptibilities coexist but no long-range order appears. We term such a metallic state as a supermetal. Our RG analysis reveals noninteracting and interacting fixed points, which draws an analogy to the $\varphi^4$ theory. We further present a finite anomalous dimension at the interacting fixed point by a controlled RG analysis, thus establishing an interacting supermetal as a non-Fermi liquid.
**1:39PM G56.00013: A symmetry-breaking analysis for non-Fermi liquids induced by order fluctuations in correlated electron systems**  
ZHENG-SU SHE (Presenter), RONG LI, Peking Univ —  
Correlated electron systems display multi-order fluctuations, which are thought of the origin for non-Fermi liquids. Here, we present a symmetry-breaking analysis for establishing this relationship. Specifically, we establish a sequence of symmetry-breakings under increasing temperature with varying orders such as density wave, nematicity and loop current in cuprates. In particular, we propose that the underlying order for strange metal (SM) is vortex fluctuation, as a fluctuating loop current excited by thermal fluctuations and field. Furthermore, a theory for scattering rate by multi-order fluctuations is constructed based on a symmetry analysis of multi-dimensional Hamiltonian with elements determined by length order function (i.e. orders' periodicity). It then yields a formula for resistivity, i.e., \( \rho = \rho_a + (\rho_b^2 + \alpha^2 T^2 + \beta^2 B^2)^{1/2} \), capturing the scaling transition from \( T^2 \) in pseudogap phase to \( T \) in SM phase, as well as anomalous magnetoresistance near quantum critical point. We report the validation evidence of dozens of cuprate samples. The most remarkable outcome is the revelation of the role of a length order function in linking macroscopic resistivity to microscopic fluctuating orders, which is essential for understanding anomalous transport in correlated electron systems.

**1:51PM G56.00014: The role of electron-electron collisions for charge and heat transport at intermediate temperatures**  
WOO-RAM LEE, Univ of Alabama - Tuscaloosa, ALEXANDER FINKELSTEIN, Texas A&M University, KAREN MICHAELI, The Weizmann Institute of Science, GEORG SCHWIETE (Presenter), Univ of Alabama - Tuscaloosa —  
We study electric, thermal and thermoelectric transport in correlated electron systems in the intermediate temperature regime, in which elastic and inelastic scattering are both important. To this end, we study the Boltzmann equation in the presence of an electric field and a temperature gradient for two cases: First, when electron-electron collisions are treated within the relaxation-time approximation while the full momentum dependence of electron-impurity scattering is included and, second, when the electron-impurity scattering is momentum-independent, but the electron-electron collisions give rise to a momentum-dependent inelastic scattering rate of the Fermi-liquid type. We find that the inelastic relaxation rate enters the electric conductivity and the Seebeck coefficient only when the momentum dependence of the electron-impurity collisions is included. Specifically, we show that inelastic processes only mildly affect the electric conductivity, but can generate a non-monotonic dependence of the Seebeck coefficient on temperature and even a change of sign. Thermal conductivity always depends on the inelastic scattering rate even for a constant elastic relaxation rate.

*This work is supported by DOE, ISF, NSF, and the College of Arts and Sciences at the University of Alabama.*
2:03PM G56.00015: Charge Transport in the Non-ergodic Extended phase of Quasi-periodic systems
SOUMI GHOSH (Presenter), JYOTSNA GIDUGU, SUBROTO MUKERJEE, Indian Institute of Science — We study the transport properties and the spectral statistics of a one-dimensional closed quantum system of spinless fermions in a quasi-periodic potential which produces a single particle mobility edge. For such systems, it has been shown that many body eigenstates can be of three different kinds: extended and ETH (energy thermalization hypothesis) obeying (thermal), localized and ETH violating (many body localized) and extended and ETH violating (non-ergodic extended). Here we investigate the non-ergodic extended phase from the point of view of level spacing statistics and charge transport. We calculate the DC conductivity and the low frequency conductivity $\sigma(\omega)$ and show that both are consistent with sub-diffusive transport. This is contrasted with diffusive transport in the thermal phase and blocked transport in the MBL phase.

Session G57 DMP: Electronic and Optical Properties of 2D Materials II
Mile High Ballroom 3A - Xiaoxiao Zhang, University of Florida - Tag(s): Focus

11:15AM G57.00001: First-principles simulation of inelastic electron beam-matter interactions and their effect on knock-on damage cross sections* ANTHONY YOSHIMURA (Presenter), Rensselaer Polytechnic Institute, DAVID LINGERFELT, PANCHAPAKESAN GANESH, JACEK JAKOWSKI, Oak Ridge National Laboratory, MICHAEL LAMPARSKI, JOEL GIEDT, Rensselaer Polytechnic Institute, BOBBY SUMPTER, Oak Ridge National Laboratory, VINCENT MEUNIER, Rensselaer Polytechnic Institute — Electron irradiation by transmission electron microscopy is an effective method for engineering the properties and morphology of 2-dimensional (2D) materials with a high degree of spatial control. It follows that many computational models have been developed to predict the rates of atomic displacements in 2D materials under such irradiation. However, while current models give reasonable predictions for conductors, they often vastly underestimate the displacement rates in insulators. In this work, we combine density functional theory with quantum electrodynamics to demonstrate how the consideration of electron-electron scattering can lead to the prediction of significantly higher displacement rates in gapped materials, reducing the disparity between theory and experiment. This new model would be a boon for materials engineers, allowing for the controlled manipulation of any 2D material for targeted functionality.

11:27AM G57.00002: A comparison study between the Lennard-Jones and DRIP potentials for friction of graphene layers*  
WOO KYUN KIM (Presenter), HUYAN LI, Univ of Cincinnati —  
Graphene is a one-atom thick 2-D material and has huge potential as a solid lubricant for small length scale devices such as nano/micro-electro-mechanical systems. Atomistic simulations such as molecular dynamics is a popular tool to study the frictional behaviors of graphene layers and it is of critical importance to accurately describe the interlayer interactions in order to give a reliable prediction on the friction of graphene. Here, two interatomic potentials, Lennard-Jones (LJ) potential and dihedral-angle-corrected registry-dependent interlayer (DRIP) potential, are examined to model interlayer interactions in friction simulations of multilayer graphene structures. While both potentials have similar attractive interactions, DRIP models the repulsive interaction by considering transverse distance and dihedral angle. In this study, we investigate the friction properties between two pristine graphene layers. The simulation results reveal that friction forces of the DRIP models are about one order of magnitude larger than those of the LJ models. It turns out that the modification of the repulsive term in DRIP introduces additional energy corrugations which increase the friction force.

11:39AM G57.00003: Structural studies of Ni-doped MoS$_2$ monolayers and polytypes using density functional theory (DFT)*  
RIJAN KARKEE (Presenter), ENRIQUE GUERRERO, DAVID STRUBBE, University of California, Merced — The structure of MoS$_2$ with strong covalent bonds in plane and weak van der Waals interactions out of plane gives rise to interesting properties for applications such as solid lubricants, optoelectronics, sensors, and electrochemical devices. Transition metal doping is found to improve the performance in tribology [MR Vazirisereshk et al., Lubricants 7, 57 (2019)] and hydrodesulfurization. We study the structure and properties of Ni-doped MoS$_2$ in the 1H and 1T monolayer and 2H and 3R bulk polytypes, using density functional theory (DFT). We calculated the formation energy of Ni at different sites (Mo and S substitution, intercalation/adsorption) to identify the most energetically favorable ones, and analyzed the energy for layer separation and the energetics of interlayer sliding. We studied the effect of Ni doping on local bonding and lattice structure at different dopant concentrations to assess possible phase changes. This work gives insight into the previously unclear structure, properties, and solid lubrication performance of Ni-doped MoS$_2$.

11:51AM G57.00004: Electrochemical Properties of Pt-Graphene Hybrid System: DFT Modeling Approach  JI IL CHOI (Presenter), SEUNG SOON JANG, Georgia Inst of Tech — Epitaxially grown Pt thin film on a graphene template is found to have a few monolayer thickness with structural stability comparable to Pt(111) surface and promising electrochemical activity. The newly synthesized thin film shows the crystalline Pt structure of quadrilateral polygon in monolayer stacking, and simple cubic-like (SC-L) stacking in bi-layer film. In this study, we present a computational research on the unique architecture of the graphene templated epitaxial platinum layers in support of the remarkable recent progress. Recently proposed strongly constrained and appropriately normed (SCAN) density function study (DFT) is employed to investigate the materials characteristics. Electrochemical activities of the system are evaluated in terms of the free energy variation in oxygen reduction reaction (ORR). In architectures, Pt exhibits registry with the C-C bridge sites along the armchair and zigzag directions forming strong covalent bonds. Here, the details of the atomistic/electronic structures and binding energies are discussed. Interestingly, the ORR can occur on both Pt and graphene surfaces. This would provide a good strategy for 1) the protection of metallic catalyst and 2) tune the electronic structure of catalyst.

12:03PM G57.00005: Ab initio investigation of the cyclodehydrogenation process for polyanthrylene transformation to graphene nanoribbons  ZHONGCAN XIAO (Presenter), North Carolina State University, CHUANXU MA, Oak Ridge National Laboratory, WENCHANG LU, North Carolina State University, JINGSONG HUANG, LIANGBO LIANG, KUNLUN HONG, AN-PING LI, BOBBY SUMPTER, Oak Ridge National Laboratory, JERRY BERNHOLC, North Carolina State University — Atomically precise synthesis of graphene nanoribbons (GNRs) may enable GNR-based nanoelectronics. We investigated GNR synthesis from DBBA molecular precursors on an Au(111) surface [1]. The growth process consists of dehalogenation/polymerization followed by cyclodehydrogenation. We investigated the latter using the nudged elastic band method within DFT. Our studies found that the metal substrate: (i) enhances the reaction energetics because adsorption of the product (GNR) on Au (111) is stronger than the adsorption of the reactant (polyanthrylene), and (ii) acts as a catalyst to lower the energy barriers for cyclodehydrogenation. In comparison, an underlying adsorbed GNR screens the metal substrate and hinders on-top GNR growth by lowering the adsorption energy and increasing the energy barriers. We also investigated electronic levels of various intermediate structures and found that molecular orbitals play an important role in directing the reaction, e.g., the injected electrons (or holes) lower the energy barrier through arenium ion effect. These findings provide new insight into GNR growth and offer guidance for the design of new graphitic structures.

**12:15PM G57.00006: Electronic Structure of twisted kagome lattice**

**ERIC SUAREZ MORELL**
(Presenter), Federico Santa Maria Technical University, FELIPE CASTRO DE LIMA, ROBERTO HIROKI MIWA, Universidade Federal de Uberlandia —

We have studied how a generic bilayer kagome lattice behave upon layer rotation. We employed a Tight Binding model with one orbital per site and found (i) for low rotational angles, and at low energies, the same flat bands structure like in twisted bilayer graphene; though, for a larger value of the magic angle.

Moreover, (ii) at high energies, due to the superstructure symmetry regions, we found the characteristics three band dispersion of the kagome lattice. In the latter, its band width decreases for lower angles confining them within a few meV. Therefore, we found in twisted kagome lattice the coexistence of two sets of flat bands in different energies and lying in different spatial regions of the bilayer system. The calculations are done for a generic kagome lattice, nonetheless we used a ratio between inter and intra layer nearest hopping similar to the value obtained in the studies of a kagome bilayer structure of Fe$_3$Se$_2$ [1] to fit experimental results.

**12:27PM G57.00007: 2D Memory Physics and Applications**

**[Invited] DEJI AKINWANDE**
(Presenter), University of Texas at Austin — This work presents the latest research progress on the atomic-level details of non-volatile resistance switching (NVRS) in 2D memory devices, otherwise known as atomristors. In particular, we will focus on memory characteristics and atomistic imaging and transport studies, together with the first principle calculations to elucidate the underlying physics. These studies provide one to one correlation between the structural and electronic properties of defects and their role in the resistance switching mechanism.

Applications from information storage to RF communication to neuromorphic computing will be highlighted.

*This work is supported in part by a PECASE, and an NSF grant.*
1:03PM G57.00008: Excitonic effects in optical-field-driven quasi 2D materials from time-dependent GW approach* [Invited] YANG-HAO CHAN (Presenter), Lawrence Berkeley National Laboratory, DIANA QIU, FELIPE H. DA JORNADA, STEVEN LOUIE, Physics, Unviersyt of California, Berkeley — Atomically thin quasi two-dimensional (2D) insulating materials exhibit novel exciton physics due to ineffective screening, quantum confinement, and topological effects. Such exciton physics has recently been studied in details experimentally and theoretically. Going beyond near-equilibrium set-up, one expects that excitonic effects also dominate the responses of out-of-equilibrium systems and can lead to interesting phenomena in optically-driven 2D materials. Using a newly developed real-time, non-equilibrium Green function method within the adiabatic GW approximation, we show that, for non-centrosymmetric 2D semiconductors, excitonic effects give rise to a strong DC current, the so-called shift current, upon even sub-bandgap frequency CW light illumination through a second-order nonlinear optical process. The frequency-dependent shift current coefficients can be enhanced by orders of magnitude by the strong e-h interactions, producing a bulk photovoltaic effect (i.e., without having to have a p-n junction) of promise for applications with appropriate materials. Furthermore, we show that, in optical-field-driven angle-resolved photoemission spectroscopy (ARPES) experiments, the energy and wavefunction of excitons may be measured directly under achievable laboratory conditions. With optical pump frequencies close to the resonance frequency for exciton excitations, distinct excitonic features manifest themselves dramatically as modulated replicas of the involved valence band states. We also find that, at higher pump intensity, the quasiparticle band energies are renormalized due to the driving optical fields.

*This work was supported by the Center for Computational Study of Excited State Phenomena in Energy Materials (C2SEPEM), which is funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division under Contract No. DE-AC02-05CH11231.
1:39PM G57.00009: Valley Polarization in Superacid-Treated Monolayer MoS$_2$* RUIJIE LI, YIFEI LI, HUIFENG TIAN, PEIQI LIAO, LEI LIU (Presenter), Department of Materials Science and Engineering, College of Engineering, Peking University, Beijing 100871, P. R. China — Point defects play a critical role in numerous phenomena such as transport, optical, and optoelectrical properties. With a lower dimensionality, due to reduced dielectric screening the interplay between charge carriers, excitons, and point defects becomes stronger in the two-dimensional materials, such as monolayer transition metal dichalcogenides (TMDCs). TMDCs have shown the fascinating spin-valley-coupled physics, which is strongly related to the lifetime of photoexcited exciton and the polarization decay time. Recently the superacid treatments have been demonstrated to increase the life time of excitons in monolayer MoS$_2$. The valley properties of treated MoS$_2$ monolayers are largely unexplored. With the variable temperature steady state PL and polarization-resolved PL spectroscopy, we show the robust absorption of superacid molecules and unexpectedly enhanced defect-bound emission under high vacuum under low temperature. The unaffected valley polarization of monolayer MoS$_2$ emphasizes the exciton trapping effect by the shallow defect levels. Our finding paves the way for the understanding of point defeat engineering for monolayer TMDCs.

1:51PM G57.00010: Anomalous CDW response in high mobility magnetic 2D material GdTe$_3$ KENNETH BURCH (Presenter), YIPING WANG, Boston college, SHIMING LEI, LESLIE SCHOOP, Princeton University — Most known magnetic van der Waals (vdW) materials are insulating or semiconducting. It is crucial to find materials with magnetic order and high-mobility for high-speed spintronic device making. Anti-ferromagnet GdTe$_3$ satisfies both down to 2D limits. It also exhibits an incommensurate charge density wave (CDW) but the role of it in GdTe$_3$ properties is still unclear. Here, we report the recent temperature and polarization dependent Raman study of GdTe$_3$, we will talk about the coupling between CDW mode and the existing phonons.
Resonant and Bound States of Charged Defects in Two-Dimensional Semiconductors*

JOHANNES LISCHNER (Presenter), MARTIK AGHAJANIAN, Imperial College London, BRUNO SCHULER, KATHERINE COCHRANE, JUN-HO LEE, CHRISTOPH KASTL, JEFFREY B. NEATON, ALEXANDER WEBER-BARGIONI, Lawrence Berkeley National Laboratory, ARASH A. MOSTOFI, Imperial College London — A detailed understanding of charged defects in two-dimensional semiconductors is needed for the development of ultrathin electronic devices. Here, we study negatively charged acceptor impurities in monolayer WS$_2$ using a combination of scanning tunnelling spectroscopy and large-scale atomistic electronic structure calculations. We observe several localized defect states of hydrogenic wave function character in the vicinity of the valence band edge. Some of these defect states are bound, while others are resonant. The resonant states result from the multi-valley valence band structure of WS$_2$, whereby localized states originating from the secondary valence band maximum at $\Gamma$ hybridize with continuum states from the primary valence band maximum at $K/K'$. Resonant states have important consequences for electron transport as they can trap mobile carriers for several tens of picoseconds.

Session G58 DCP DCOMP DPOLY DCMP: DFT and Beyond V Mile High Ballroom

3B - Carsten Ullrich, Univ of Missouri - Columbia - Tag(s): Focus
Weizmann Institute of Science — Optical and excited-state phenomena are key ingredients in functional materials characterization, dominating emerging applications in broad areas of photophysics. Excited-state properties, including linear and non-linear light absorption, as well as radiative and non-radiative exciton decay processes, are strongly related to the material structure and composition. Recent experimental advances allow a controlled fabrication of structurally complex materials, along with close tracking of excited-state processes in them. However, a theoretical realization of the underlying interactions and subsequent design rules in such materials is highly challenging, as it demands a predictive description of the involved excitations, strongly depending on the structural perturbation. In this talk, I will describe a computational assessment of the relation between excitonic phenomena and material structure and design, using many-body perturbation theory within the GW and Bethe-Salpeter equation (GW-BSE) approach. I will discuss the effect of atomic defects and heterostructures on the excitonic properties in layered transition metal dichalcogenides (TMDs), where the structural complexity leads to mixed transitions between states of different nature and localization, determining unique and tunable selection rules and absorption. I will further present a GW-BSE-based approach to study exciton transport with relation to material structure and symmetry, demonstrated on selected systems of varying dimensionalities.

Many-body perturbation theory (MBPT) has emerged as a state-of-the-art approach for quantitatively accurate prediction of (opto)electronic properties of materials. However, the computational cost of MBPT motivates the search for simpler methods, particularly those based on density functional theory (DFT), to enable the study of larger and more complex systems. In particular, tuned and screened range-separated hybrid (SRSH) hybrid methods have been shown to provide MBPT accuracy at the cost of hybrid DFT for many materials. We test the accuracy of time-dependent (TD)SRSH for describing the optoelectronic properties of defective semiconductors by the study of point defects in bulk GaN. We first show that the predicted quasiparticle gap and low-energy excitation spectra of (TD)SRSH and MBPT agree well in pristine GaN and GaN containing a single nitrogen vacancy, establishing the accuracy of the method. Aided by the reduced computational cost of (TD)SRSH, we then report on a series of technologically relevant point defects in GaN. This study indicates that TDSRSH is a computationally feasible approach for quantitatively accurate first-principles modeling of defective semiconductors.

12:03PM G58.00003: UNDERSTANDING EXCITONS IN STACKED PERYLENE DIIMIDE DERIVATIVES*  
ALIYA MUKAZHANOVA (Presenter), Materials Science and Engineering, Boston University, KASIDET JING TRERAYAPIWAT, Department of Chemistry, Boston University, SAHAR SHARIFZADEH, Department of Electrical and Computer Engineering, Boston University — π-stacked organic chromophores are promising class of materials for optoelectronics with their electronic properties strongly dependent on the chemical structure of the molecule and inter-molecular interactions. Here, we investigate the optical properties of recently synthesized stacked perylene diimide derivatives via time-dependent density functional theory with a Franck-Condon Herzberg-Teller approximation of vibronic effects, validating our approach by comparison to measurement. By stacking the molecules along a DNA-like backbone and varying the number of stacked molecules from one to three, we determine the role of inter- and intra- molecular interactions on the nature of optical excitations. We determine that for stacked molecules, ground-state vibrational excitations play an important role in the optical absorption spectrum, which we account for via molecular dynamics. Additionally, we apply a nonadiabtic dynamics method to study the role of the backbone on evolution of excited-states. We demonstrate that inter-molecular interactions and backbone strongly influence optical properties, providing new design strategies for efficient optoelectronic materials.

12:15PM G58.00004: First-principles investigations of structure and vibrations of c(4x2) PF₃ on Cu(001)  
NIMA KARIMITARI (Presenter), STEVEN LEWIS, University of Georgia — We use first-principles density functional theory (DFT) to study the structure and vibrational dynamics of PF₃ on the Cu(001) surface in the c(4x2) geometry. This system presents a unique opportunity to consider the complex interplay at work when a molecule with 3-fold symmetry binds to a surface with 4-fold symmetry. Our calculations find an upright structure for the PF₃ molecules, in contrast to experimental claims. The phonon analysis reveals an interesting coupling between adsorbate modes, surface mods and bulk modes. We will present detailed calculational evidence, including phonon density of states and projected density of states to support the rich structural and vibrational behavior that this system affords.
12:27PM G58.00005: First-principles simulations of photocatalytic systems for hydrogen production*  SAMUEL LEMAY (Presenter), GABRIEL ANTONIUS, Hydrogen Research Institute, Université du Québec à Trois-Rivières — Hydrogen offers a green alternative to fossil fuels, as it can be used in combination with fuel cells to propel an electric vehicle. In order to assist the design of photocatalytic systems for hydrogen production, we perform first-principles calculations of the electronic structure of several catalysts and attempt to predict their efficiency for hydrogen evolution reactions. One class of catalysts are coordination complexes composed of a metallic atom surrounded by organic ligands. In the present work, we focus on Co(bpy)2 and Co(bpym)2 where (bpy) is a bipyridine ligand and (bpym) is a bipyridine mimic. We rely on density functional theory (DFT) to compute the structural parameters of the molecules, their formation energy, and electronic energy levels. We aim to calculate the energy levels of the neutral, charged, and hydrogenated states of the molecules and compare it to cyclic voltammetry measurements.

*We acknowledge the support of the Natural Sciences and Engineering Research Council of Canada (NSERC), [funding reference numbers RGPIN-2019-07149 and DGECR-2019-00008], as well as support from Université du Québec à Trois-Rivières. The computational resources were provided by Calcul Québec and Compute Canada.

12:39PM G58.00006: The Dirac equation and its implications for density functional theory-based calculations of materials containing heavy elements  DANIEL A REHN (Presenter), JOHN M WILLS, ANN E MATTSSON, Los Alamos National Laboratory — Electronic structure calculations based on density functional theory (DFT) typically give quantitatively accurate predictions for ground-state properties of materials containing light elements. For materials containing heavy elements, relativistic effects play an increasingly important role and in principle, a formulation of DFT based on the Dirac equation is needed to properly incorporate relativistic effects. Working towards that goal, we have developed a code, called dirac-fp, that solves the Dirac-Kohn-Sham equations under the assumption of a vanishing orbital current. The dirac-fp code is based on the full potential linear muffin tin orbital (FP-LMTO) code RSPt, but solves the Dirac-Kohn-Sham equations throughout the entire computational cell. To assess the results of the Dirac-Kohn-Sham (Dirac) approach, we compare the ground state properties to the scalar relativistic (SR) and scalar relativistic+spin-orbit coupling (SR+SO) approaches for three different non-magnetic FCC materials: thorium, aluminum, and gold, in which relativistic effects should be strong, negligible, and intermediate, respectively. We find that only the Dirac approach is able to provide consistent results in the electronic structure and ground state properties across all three materials.
12:51PM G58.00007: Effect of functional -NH2 groups on sensitization of 3,6-diaminocarbazole towards Picric Acid VISHAL KUMAR (Presenter), SOUMITRA SATAPATHI, Indian Inst of Technology Roorkee — Due to the significance of explosive detection for homeland security and environmental protection, the research of new materials and methodologies for sensing electron-deficient explosive nitroaromatics is urgently imperative. In this paper we demonstrate an opto-chemical sensor for explosive detection by using a carbazole derivative, namely 3,6-diaminocarbazole (DAC) (Φf=49%), was synthesized through controlled nitration of the carbazole (Φf=42%) with fuming nitric acid. As a proof of concept, electron-deficient explosive molecule 2,4,6-trinitrophenol (TNP) is used as a model analyte to our sensor with LOD 3.7µM. In solution, PL signal from highly electron-rich DAC gets quenched upon addition of aliquots of TNP caused by photo-induced electron and resonance energy transfer i.e. quantified by Stern-Volmer constant (KS\text{V}= 4.1\times10^4 \text{ M}^{-1}) which is higher than KS\text{V}=3.3\times10^4 \text{ M}^{-1}, valuated for carbazole. The quenching mechanism was further established by time-resolved PL and steady state absorption spectroscopy which was found to be a mixture of static and dynamic in nature as lifetime of DAC (2.18 ns) is reduced to 1.24 ns for TNP. As a conclusion, results indicate that major response of this sensitivity enhancement to TNP originates from Föster Resonance Energy Transfer between DAC and TNP.

1:03PM G58.00008: Charge Transport Properties of Biomolecules* ABHISHEK AGGARWAL (Presenter), Indian Institute of Science - Dept of Physics, SAIENTAN BAG, Institute of Nanotechnology, Karlsruhe Institute of Technology, RAVINDRA VENKATRAMANI, Department of Chemical Sciences, Tata Institute of Fundamental Research, MANISH JAIN, PRABAL K MAITI, Indian Institute of Science - Dept of Physics — Double-stranded DNA (dsDNA) and dsRNA hold great promises in molecular electronics. We characterize the charge transport properties of dsRNA for different sequences and compare them with similar sequences of dsDNA in two extreme charge transport regimes – incoherent charge hopping regime and coherent electron transport regime. We find that the relative conductance of A-form dsRNA and B-form dsDNA depends on the mechanism of charge transport. This is attributed to various structural differences in dsDNA and dsRNA. We also study the effect of stretching and propose a method to detect conformational changes using electrical measurements. Despite the twist-stretch coupling of dsRNA and dsDNA being different under external force, dsRNA shows similar structural polymorphism to dsDNA under different pulling protocols. Our atomistic MD simulations show that overstretching dsRNA along the 3’ ends (OS3) leads to the emergence of S-RNA whereas overstretching along the 5’ ends (OS5) leads to melting of dsRNA. Using the dsRNA morphology from MD simulations, we use a multiscale method involving ab initio DFT calculations and Kinetic Monte Carlo (KMC) simulations to estimate the conductance of dsRNA and find that the conformational changes drastically affect its conductance.

*MHRD, IISc
1:15PM G58.00009: Cyanide Bridged Platinum-Iron Complexes as Cisplatin Prodrug Systems: Design and Computational Study  ARIELA KASPI-KANETI (Presenter), SRIJANA BHANDARI, BARRY DUNIETZ, Kent State Univ - Kent —

We present design principles of cyanide bridged Platinum-Iron complexes as novel Platinum(IV) anti-cancer prodrugs that bear the potential of high selectivity towards cancerous cells. The proposed molecular system can release up to six cisplatin anticancer agents per prodrug unit. This functionality of the prodrug is addressed through density functional theory (DFT) calculations that are presented as a demonstration of the proposed principle.

1:27PM G58.00010: Detection of DNA nucleotides with Nanopores and Nanogaps from 2D Materials beyond Graphene: First Principle Studies  BENJAMIN TAYO (Presenter), Univ of Central Oklahoma — Sequencing the DNA at the resolution of individual DNA bases is an important problem whose solution could lead to cost-effective methods for sequencing the DNA, leading to revolutions in the field of genomics and personalized medicine. We present the results of computational studies on nano-bioelectronic devices combining the superb properties of 2D materials beyond graphene with DNA nucleotides. We anticipate our studies to shed useful insights that can help to address two major challenges in current sequencing technologies: 1) strong coupling between 2D materials and nucleotides is expected to produce large signal-to-noise ratio compared to devices using graphene due to adsorption of nucleotides on graphene surface, or devices based on probing ionic currents, which often produce very low signal-to-noise ratio, 2) strong coupling between 2D materials and nucleotides is anticipated to produce large tunneling currents capable of accomplishing both spatial and temporal resolution at the single-base level. The performance of our proposed device for single-base sequencing will be evaluated by employing density functional theory and the nonequilibrium Green’s function method to investigate the transverse conductance properties of nucleotides inside the nanogap or nanopore.
1:39PM G58.00011: Electronic and optical properties of halide perovskite quantum dots: a DFT and TDDFT study. ATHANASIOS KOLIOGIORGOS (Presenter), Control Engineering, Czech Technical University in Prague, CHRISTOS GAROUFALIS, IOSIF GALANAKIS, SOTIRIOS BASKOUTAS, Materials Science, University of Patras —
Perovskite quantum dots (QDs) constitute a novel and rapidly developing field of nanotechnology with promising potential for optoelectronic applications. However, few perovskite materials for QDs and other nanostructures have been theoretically explored. In this study, we present a wide spectrum of different hybrid halide perovskite cuboid-like QDs with the general formula of ABX₃ (A = Cs, CH₃NH₃; B = Pb, Sn, Ge, Ca, Sr and X = Cl, Br, I) with varying sizes below and near the Bohr exciton radius. Density functional theory (DFT) and time-dependent DFT calculations were employed to determine their structural, electronic, and optical properties. Our calculations include both stoichiometric and non-stoichiometric QDs, and our results reveal several materials with high optical absorption and application-suitable electronic and optical gaps. Our results also reveal whether the stoichiometric or non-stoichiometric model is closer to experiment. Finally, we explore a computational approach for the study of resonance energy transfer between 2 nanostructures of different sizes. Our study highlights the potential as well as the challenges and issues regarding nanostructured halide perovskite materials, laying the background for future theoretical and experimental work.

1:51PM G58.00012: Efficient and Accurate Fully Relativistic Density Functional Treatment for Molecules and Periodic Solids* RUNDONG ZHAO (Presenter), VICTOR YU, Duke University, KIMBERLY ZHANG, University of California, Irvine, YUNLONG XIAO, Peking University, YONG ZHANG, WENJIAN LIU, Shandong University, VOLKER BLUM, Duke University — A fully relativistic density functional method (called quasi-four-component algorithm, Q4C) in combination with numeric atom-centered orbital (NAO) basis functions is presented. Q4C initially projects the atomic solution to (electron-only) positive-energy states and deals with only two components but restores the negative-energy component in a second step; it therefore retains the full precision of traditional four-component relativistic methods. While Q4C inherently reduces the dimension of the Hamiltonian matrix and correspondingly the computational demand in matrix diagonalization, the adoption of localized NAO basis functions further reduces the computational demand in real space operations, enabling us to explore large and complex systems containing heavy elements fully relativistically. Here, we report benchmarks for the properties of a series of common periodic materials and molecules. Additionally, the band structure of a much larger system, i.e. the 2D hybrid organic-inorganic perovskite (2D-HOIP) (4-FPEA)₂PbI₄ (containing 94 atoms per unit cell) is reported, showing the code’s applicability to large systems.

2:03PM G58.00013: An Electronic Structure Approach to Understand Charge Transfer & Transport in Organic Semiconducting Materials  SRIJANA BHANDARI (Presenter), Kent State Univ - Kent — Effective design of optoelectronic devices requires understanding of the role of the molecular environment. However, widely used forms of DFT and TDDFT fail to accurately describe the frontier orbital gap and charge transfer states of such molecular systems in the condensed phase. Recently we implemented a novel approach combining screened RSH (SRSH) with polarized continuum model (PCM), where long range electrostatic interactions are consistently screened by a 1/e factor (e is the solid-state dielectric constant). Using this new approach, we achieved a highly efficient quantum chemical procedure to obtain condensed phase IP and EA based on single molecule calculations and the correct charge transfer energies of a complex system.

Using this approach, we address molecular conductance where DFT has an established tendency to overestimate the conductance. Here, we develop the approach to address non-equilibrium conditions by using RSH functionals within NEGF formulation to study conductance. We then develop the approach to study NDR based on (phenylene ethynylene) derivatives.

We compare the RSH-NEGF results with alternative DFT-NEGF approaches to highlight the importance of using an approach based on physically significant frontier orbitals.

Tuesday, March 3, 2020 11:15 AM - 1:39 PM

Session G59 DMP: Ferromagnetic Kagome Metals Mile High Ballroom 3C

11:15AM G59.00001: Spin dynamics of the isotropic kagome ferromagnet Fe₃Sn₂  JEFFREY LYNN (Presenter), REBECCA DALLY, NIST Center for Neutron Research, National Institute of Standards and Technology, NIRMAL GHIMIRE, NISHCHAL THAPA MAGAR, Department of Physics and Astronomy, George Mason University, DANIEL PHELAN, JOHN MITCHELL, Materials Science Division, Argonne National Laboratory — The giant anomalous Hall effect in the itinerant kagome magnet Fe₃Sn₂ was recently attributed to massive Dirac fermions resulting in a Berry curvature in the ferromagnetic phase [1], with a topologically non-trivial field-dependent spin texture phase discovered[2], demonstrating an intimate relationship between the electronic and magnetic properties in this strongly correlated electron material. Here we present a new perspective on Fe₃Sn₂ by studying the magnetic excitations near \( q = 0 \) using inelastic neutron scattering. The results on polycrystalline samples show this material to be an isotropic ferromagnet near its \( T_C \) of 660 K, where we find a negligible spin gap, and large spin-wave stiffness. The moments initially point along the \( c \)-axis and slowly rotate over the course of several hundred degrees towards the \( ab \)-plane. This indicates the “soft” nature of the ferromagnet, which is at odds with the argument that anisotropy is responsible for some the materials’ properties elsewhere in phase space.

Additionally, magnetic susceptibility and magnetization measurements agree with our neutron diffraction results showing this sample does not undergo a re-entrant spin-glass phase as reported by some.

11:27AM G59.00002: Scanning Tunneling Microscopy Study of Fe$_3$Sn$_2$*  
JORGE OLIVARES RODRIGUEZ (Presenter), ANUVA AISHWARYA, LIN JIAO, VIDYA MADHAVAN, University of Illinois at Urbana-Champaign — The peculiar geometry of the Kagome lattice, composed of corner-sharing triangles, has been known to be a fertile ground for exotic quantum phases since theory predicts the possible coexistence of topological and frustrated magnetic states stemming from this structure. The recently rediscovered metallic ferromagnet Fe$_3$Sn$_2$, consisting of two kagome bilayers (Fe$_3$Sn) layers separated by a honeycomb Sn layer, is seemingly a good candidate to explore the interplay between frustrated magnetism and topological band structure due to recent reports which include the observation of massive dirac fermions and the anomalous Hall effect. In addition, it has also been reported that its electronic structure can be tuned by changing its magnetic moments or temperature, making it a viable candidate for spintronic applications. Here we present a scanning tunneling microscopy/spectroscopy study of Fe$_3$Sn$_2$ at low temperatures and under a magnetic field.

11:39AM G59.00003: Defects in magnetic Weyl semimetal Co$_3$Sn$_2$S$_2$*  
QIANG ZOU (Presenter), MINGMING FU, MINA YOON, CNMS, Oak Ridge National Lab, RUI XUE, DAVID MANDRUS, University of Tennessee, Knoxville, ZHENG GAI, CNMS, Oak Ridge National Lab — In Co$_3$Sn$_2$S$_2$, a magnetic Weyl semimetal with kagome-lattice, the existence of bulk Weyl nodes, which are formed under broken inversion or time-reversal symmetry, creates nontrivial topological properties, for example, robust Giant anomalous hall effect. The surface–bulk correspondence ensures the bulk bands related topological “Fermi arc” surface bands dispersion. In this presentation, we use low temperature high magnetic field scanning tunneling microscope, spin polarized STM, and quasiparticle interference (QPI) to study the influence of local defects including magnetic and nonmagnetic vacancies and adatoms to the Weyl nodes movement. Co and Sn vacancies in the Kagome-lattice are identified, their behavior under magnetic field are studied. S adatoms in 1D forms are compared with individual adatoms. The interplay among topology, defects and magnetism are discussed for the understanding of the involved quantum phenomena.

*This research was conducted at the Center for Nanophase Materials Sciences, which is a DOE Office of Science User Facility.
Temperature dependent conductivity in magnetic Weyl semimetal Co$_3$Sn$_2$S$_2$ with terahertz spectroscopy

ELIZABETH FULLER (Presenter), EVAN JASPER, YUFEI LI, ROLANO VALDES AGUILAR, Ohio State Univ - Columbus, RUI XUE, DAVID MANDRUS, University of Tennessee, Knoxville — The recently discovered Weyl semimetal, Co$_3$Sn$_2$S$_2$, is attractive for its intrinsic ferromagnetic behavior below $T_c \sim 175$ K with almost full spin polarization, i.e. half-metallicity. Previous studies$^{1,2}$ report evidence of a highly tunable, large anomalous Hall effect (AHE) with change in temperature. We utilize spectroscopic methods in the terahertz range to measure the optical conductivity in a single crystal Co$_3$Sn$_2$S$_2$ within the 8 K to 290 K temperature range. We observe a clear downward shift in the reflectance of the crystal with increasing temperatures near the ferromagnetic transition and a similar trend for low temperatures. We will discuss these measurements in the context of the Anomalous Hall conductivity that varies with shifts in Weyl node position.

*This work is supported by the Center for Emergent Materials, an NSF MRSEC, under grant DMR-1420451.

Fermi-arc diversity on surface terminations of the magnetic Weyl semimetal Co$_3$Sn$_2$S$_2$

NURIT AVRAHAM (Presenter), NOAM MORALI, PRANAB KUMAR NAG, RAJIB BATABYAL, Weizmann Institute of Science, LIU ENKE, Beijing National Laboratory, QIUNAN XU, YAN SUN, Max Planck Dresden, BINGHAI YAN, Weizmann Institute of Science, CLAUDIA FELSER, Max Planck Dresden, HAIM BEIDENKOPF, Weizmann Institute of Science — Bulk–surface correspondence in Weyl semimetals ensures the formation of topological “Fermi arc” surface bands whose existence is guaranteed by bulk Weyl nodes. By investigating three distinct surface terminations of the ferromagnetic semimetal Co$_3$Sn$_2$S$_2$, we verify spectroscopically its classification as a time-reversal symmetry-broken Weyl semimetal. We show that the distinct surface potentials imposed by three different terminations modify the Fermi-arc contour and Weyl node connectivity. On the tin (Sn) surface, we identify intra–Brillouin zone Weyl node connectivity of Fermi arcs, whereas on cobalt (Co) termination, the connectivity is across adjacent Brillouin zones. On the sulfur (S) surface, Fermi arcs overlap with nontopological bulk and surface states. We thus resolve both topologically protected and nonprotected electronic properties of a Weyl semimetal.
12:15PM G59.00006: Large anomalous Hall and planar Hall effect in magnetic Weyl semimetal $\text{Co}_3\text{Sn}_2\text{S}_2$  
SHUO-YING YANG (Presenter), Max Planck Institute of Microstructure Physics, JONATHAN NOKY, JACOB D GAYLES, Max Planck Institute for Chemical Physics of Solids, FASIL KIDANE DEJENE, Max Planck Institute of Microstructure Physics, YAN SUN, Max Planck Institute for Chemical Physics of Solids, ENKE LIU, Institute of Physics, Chinese Academy of Science, MAZHAR ALI, Max Planck Institute of Microstructure Physics, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, STUART PARKIN, Max Planck Institute of Microstructure Physics — Weyl fermions are chiral massless fermions manifested in crystalline solids by spin split conduction and valence bands crossing at discrete points. Time-reversal-symmetry-broken Weyl semimetals (WSMs) have attracted particular attention because of their interesting interplay between intrinsic magnetism and topologically nontrivial electrons. In this work, we perform detailed transport studies on a magnetic Weyl semimetal, $\text{Co}_3\text{Sn}_2\text{S}_2$. Nanoplates as thin as 180 nm were grown via chemical vapor transfer methods. Through magneto-transport measurements, we report a large intrinsic anomalous Hall conductivity generated by a large Berry curvature from the Weyl nodes. The anomalous Hall conductivity is robust against both increased temperature and charge conductivity, reaching $\sim 1420 \text{ ohm}^{-1} \text{ cm}^{-1}$. In addition, we discuss the observation of a large planar Hall effect (PHE) in $\text{Co}_3\text{Sn}_2\text{S}_2$. We carefully examined all possible origins of the PHE including ferromagnetism, orbital magnetoresistance and the chiral anomaly. Our analysis reveals that even though negative magnetoresistance (NMR) was not seen, the observed PHE is chiral anomaly dominated. Our results show how multiple PHE contributions can be disentangled in a magnetic WSM system and suggest that PHE is a sensitive probe of Weyl transport.

12:27PM G59.00007: Exchange biased Anomalous Hall Effect driven by frustration in a magnetic Kagome lattice*  
ELLA LACHMAN (Presenter), RYAN MURPHY, NIKOLA MAKSIMOVIC, ROBERT KEALHOFER, SHANNON C HALEY, University of California, Berkeley, ROSS MCDONALD, Los Alamos National Laboratory, JEFFREY R LONG, JAMES ANALYTIS, University of California, Berkeley — $\text{Co}_3\text{Sn}_2\text{S}_2$ is a ferromagnetic Weyl semimetal that has been the subject of intense scientific interest due to its large anomalous Hall effect (AHE). We show that the coupling of this material's topological properties to its magnetic texture leads to a strongly exchange biased AHE, and argue that this is likely caused by coexistence of ferromagnetism and spin glass phases. The spin glass is being driven not by disorder, but by the geometric frustration intrinsic to the Kagome network of magnetic ions. Both phases are thought to originate from the Co spin system, in an interesting display of Exchange Bias emanating from a single magnetic phase. Magnetism plays an important role in the robustness of the QAHE in magnetically doped topological insulators, and may play a crucial role in unlocking the possibility of a QAHE in low-dimensional structures of $\text{Co}_3\text{Sn}_2\text{S}_2$.

12:39PM G59.00008: High field quantum oscillation studies of Dirac electrons in iron-based kagome lattice metals*  LINDA YE (Presenter), MIN GU KANG, Massachusetts Institute of Technology, MUN K. CHAN, ROSS MCDONALD, National High Magnetic Field Laboratory, LANL, DAVID E GRAF, National High Magnetic Field Laboratory-Florida State University, ABRAHAM L LEVITAN, MINYONG HAN, Massachusetts Institute of Technology, DAVID CHARLES BELL, Harvard University, MADHAV PRASAD GHIMIRE, IFW Dresden, SHIANG FANG, Harvard University, JHIH-SHIH YOU, JORGE I. FACIO, IFW Dresden, EFTHIMIOS KAXIRAS, Harvard University, JEROEN VAN DEN BRINK, IFW Dresden, RICCARDO COMIN, JOSEPH G CHECKELSKY, Massachusetts Institute of Technology — The kagome lattice has long been theoretically known to harbor Dirac dispersions together with a dispersionless (flat) band. The relevance of the kagome lattice model in the context of electronic structures has recently been established in a class of binary hexagonal iron stannides, where Dirac dispersions derived from Fe 3d electrons are observed at Brillouin zone corners in photoemission studies [1,2]. Here we report high magnetic field quantum oscillation studies of Dirac electrons in these iron-based kagome metals including ferromagnetic Fe3Sn2 [3] and antiferromagnetic FeSn [2]. In Fe3Sn2 we observe a doublet of quasi-2D bulk Dirac electrons while a single bulk Dirac pocket is identified in FeSn. We further discuss the impact of crystallographic stacking and magnetic order on the Dirac electronic states in Fe3Sn2 and FeSn. References: [1] L. Ye, M. Kang et al., Nature 555 638-642 (2018). 12:51PM G59.00009: Topological Chern bands for electrons and magnons realized in one Kagome ferromagnet: CoCu3(OH)6Cl2*  ZHUORAN HE (Presenter), GANG XU, Huazhong University of Science and Technology, BIAO LIAN, Princeton University — We study the topological electron bands and spinon bands in the ferromagnetic phase of CoCu3(OH)6Cl2. The Cu ions with fractional valence and magnetic moments form a 3D trigonal crystal stacked from 2D Kagome layers. A t-J model with spin-orbit coupling is constructed from the hybridized Wannier orbitals and studied using the Schwinger bosons to calculate the spinon bands. The Chern numbers of the electron and spinon bands reveal their nontrivial topological properties and implications on the spintronic transport properties are discussed. Our work provides an example for the study of interactions between two topological systems and sheds light on the understanding of correlated electrons in magnetic topological materials.

*The authors thank the support from the MOST and NSFC, the Thousand Young Talents Program, and cooperation with Princeton University.
1:03PM G59.00010: Electronic structure of a metallic ferromagnetic pyrite

IÑIGO ROBREDO
(Presenter), Donostia International Physics Center, NIELS SCHRÖTER, PSI, SEBASTIAN KLEMENZ, ROBERT KIRBY, Princeton, ANDREAS P SCHNYDER, MPI Stuttgart, AITOR BERGARA, EHU/UPV, VLADIMIR STROKOV, JONAS A. KRIEGER, TIANLUN YU, PSI, FERNANDO DE JUAN, MAIA G VERNIORY, Donostia International Physics Center, LESLIE SCHOOOP, Princeton — In this work we present combined experimental and theoretical results to elucidate electronic and magnetic properties of metallic cobalt pyrite CoS$_2$. On one side we reveal that the Density Functional Theory predicted band structure is in good agreement with angular resolved photoemission spectroscopy (ARPES) measurements, performed for the first time. Further studying its band structure we discovered that this material exhibits topological behaviour. Close to the Fermi level, we found a potential 'New Fermion', a 4-dimensional magnetic band crossing protected by cubic, non-symmorphic magnetic symmetries, along with several neighbouring Weyl fermions. We finally analyze the surface states and identify surface Fermi arcs.

1:15PM G59.00011: Systematic analysis of topological and magnetic properties of materials related to MnBi$_2$Te$_4$ by substitution

SUGATA CHOWDHURY (Presenter), KEVIN GARRITY, FRANCESCA TAVAZZA, MML, NIST — The search for materials with axion insulator phases has motivated extensive research about interactions between topological surface states and symmetry-breaking magnetic ordering, with possible applications in spintronics and quantum information. Recently, experimental and theoretical works have focused on MnBi$_2$Te$_4$, which is predicted to display this phase. In this work, we have looked at alternative elements in the same septuple layer structure by considered a series of 3d transitions metal from V to Ni as the magnetic element, as well as Sb for Bi and Se for Te. We study the topological properties and magnetic properties of new candidate materials. Our calculations reveal several potential topological materials, with properties depending on the filling of d electrons and the magnetic ordering. We also discuss the optical properties and electron phonon interactions of those materials. These types of stoichiometric magnetic materials are an excellent candidate for future topological devices.

1:27PM G59.00012: Phase transition from Mn-Bi$_2$Te$_3$ to MnBi$_2$Te$_4$

KEJING ZHU (Presenter), MENGHAN LIAO, YAN GONG, KE HE, QIKUN XUE, Tsinghua University — The realization of MnBi$_2$Te$_4$ film opens the vision to search rich topological effects in intrinsic magnetic topological insulator. In the cleaved single crystal samples, the high resolution angle-resolved photoemission spectroscopy (ARPES) shows the clear topological electronic structures, and the transverse resistance reaches quantization in a high external magnetic field. Those results indicate that 124 family materials can be an ideal platform for further exploring various topological phenomena. But in Mn-Bi-Te system, 124 structure is not the solely stable phase. Mn atoms can replace the position of Bi atoms to form a Mn doped Bi$_2$Te$_3$ phase. MnBi$_4$Te$_7$ and Mn$_2$Bi$_2$Te$_5$ are also predicted to be existed in this system. In order to give a clear phase diagram and give an instruction of growing Mn-Bi-Te material, we investigate the evolution of electronic energy band structures with increasing Mn doping level. We also study the temperature influence on the Mn-Bi-Te material.
G59.00013: Abnormal Negative Magnetoresistance and Exceptional Hall Component in Magnetic Weyl Semimetal $\text{Co}_3\text{Sn}_2\text{S}_2$ Nanodevices*  

QI ZENG (Presenter), GANGXU GU, JIANLEI SHEN, ENKE LIU, WENHONG WANG, YONGQING LI, Chinese Academy of Sciences — Recently, the first magnetic Weyl semimetal $\text{Co}_3\text{Sn}_2\text{S}_2$ has been discovered[1-3]. For topological related spintronics applications in low dimensions, the growth and physical researches of $\text{Co}_3\text{Sn}_2\text{S}_2$ thin films are highly desired. In this work, we synthesized single-crystalline $\text{Co}_3\text{Sn}_2\text{S}_2$ nanoflakes with thickness from 100 to 30 nm by chemical vapor method. The nanodevices were prepared by using microfabrication. The nanoflakes show stable Curie temperature around 181 K, high anomalous Hall conductivity of 800 S cm$^{-1}$, large coercive force up to 5.5 T, and high quality with RRR up to 20. At low temperatures, the decreased resistance is observed when the external magnetic field is lower than the coercive field and antiparallel to the internal magnetization, showing an abnormal negative magnetoresistance. Meanwhile, an exceptional Hall component, after subtracting the normal and anomalous Hall, is also found before the magnetic domain is switched. A value of this component is observed up to three times larger than the anomalous Hall contribution. Exotic behaviors were observed in magnetic Weyl semimetal $\text{Co}_3\text{Sn}_2\text{S}_2$ nanodevices.

G59.00014: Pressure Driven Topological and Quantum Phase Transition on Magnetic Weyl Kagome Lattice

QI ZENG, Chinese Academy of Sciences, Institute of Physics, QIUSHI YAO, Southern University of Science and Technology, JIANLEI SHEN, Chinese Academy of Sciences, Institute of Physics, HONGYI SUN, Southern University of Science and Technology, WENHONG WANG, Chinese Academy of Sciences, Institute of Physics, YONGGANG WANG, Center for High Pressure Science and Technology Advanced Research (HPSTAR), QIHANG LIU, Southern University of Science and Technology, ENKE LIU (Presenter), Chinese Academy of Sciences, Institute of Physics — Recently, the Shandite compound $\text{Co}_3\text{Sn}_2\text{S}_2$ has been proved as a magnetic Weyl semimetal[1-3]. $\text{Co}_3\text{Sn}_2\text{S}_2$ possesses the out-of-plane magnetic Kagome lattice formed by Co atoms, which dominates the behaviors of Weyl fermions in this system. In this work, we performed experiments and theoretical calculations under high pressures to study the evolution of the topological state in $\text{Co}_3\text{Sn}_2\text{S}_2$. Experimental results show that the Curie temperature, anomalous Hall conductivity, and coercitive force of Hall curves decrease with increasing pressure. The ordinary Hall coefficient changes sign at a critical pressure, producing a maximum of the carrier concentration and a switch of the carrier types. Around 40 GPa the magnetic order finally disappears and the system goes into the protection of time reversal symmetry, becoming a topological insulator phase above 40 GPa. The calculations further found that additional Weyl nodes emerge with increasing pressure, showing low- and high-pressure Weyl fermion states. The topological and quantum phase transition is observed under pressure in the magnetic Weyl semimetal $\text{Co}_3\text{Sn}_2\text{S}_2$.

*NSFC: 11974394 and 51722106
G59.00015: On the anisotropies of magnetization and electronic transport of magnetic Weyl semimetal Co$_3$Sn$_2$S$_2$*  

JIANLEI SHEN (Presenter), QI ZENG, ENKE LIU, Chinese Academy of Sciences — Co$_3$Sn$_2$S$_2$, a quasi-two-dimensional system with kagome lattice, has been found as the first magnetic Weyl semimetal recently[1-3]. In this work, the anisotropies of magnetization and transport properties of Co$_3$Sn$_2$S$_2$ were investigated. High field measurement results indicate this semimetal shows a giant magnetocrystalline anisotropy with an out-of-plane saturation field of 0.9 kOe and an in-plane saturation field of 230 kOe at 2 K, showing a magnetocrystalline anisotropy coefficient $K_u$ up to $8.3 \times 10^5$ J m$^{-3}$, which indicates that it is extremely difficult to align the small moment of 0.29 μB/Co on the kagome lattice from $c$ axis to ab plane. The out-of-plane angular dependences of Hall conductivity further reveal strong anisotropies in Berry curvature and ferromagnetism, and the vector directions of both are parallel with each other. For in-plane situation, the longitudinal and transverse measurements for both $I \parallel a$ and $I \perp a$ cases show that the transport on the kagome lattice is isotropic. These results provide essential understanding on the magnetization and transport behaviors for the magnetic Weyl semimetal Co$_3$Sn$_2$S$_2$.

11:15AM G60.00001: Ultrathin epitaxial Na3Bi films for topological electronics [Invited]  
MICHAEL FUHRER (Presenter), Monash University — Selected by Focus Topic Organizer (Seongshik Oh and Peter Armitage)
11:51AM G60.00002: Polymerized triptycene as a candidate material of higher-order topological insulator*  TOMONARI MIZOGUCHI (Presenter), MINA MARUYAMA, SUSUMU OKADA, YASUHIRO HATSUGAI, Univ of Tsukuba — Higher-order topological insulators (HOTIs) have attracted growing attention as a novel class of topological state of matter, where boundary states, protected by topological natures of Bloch wave functions in a bulk, appear at boundaries with co-dimension larger than one. So far, various theoretical models for HOTIs have been proposed, and it is highly desirable to search suitable materials to realize the HOTIs. In this presentation, we propose that a class of carbon-based materials called polymerized triptycene is a promising platform for a two-dimensional second-order topological insulator. The materials are composed of triptycene molecules and phenyl rings connecting the triptycene molecules. In this class of materials, the C₆ rings form a kagome-type network, which becomes a platform to realize the HOTI when introducing the “breathing” structure. We show by the analysis of the tight-binding model that the corner states appear under the appropriate choice of the sample edges. We also demonstrate that the corner states are topologically protected by the bulk topological invariant, or the Z₃ Berry phase, that characterizes HOTIs.

12:03PM G60.00003: Apatite as a higher-order topological insulator with 2/3-filled hinge states*  MOTOAKI HIRAYAMA, RIKEN, RYO TAKAHASHI, SATORU MATSUISHI, HIDEO HOSONO, SHUICHI MURAKAMI (Presenter), Tokyo Inst of Tech - Tokyo — In our previous work we have shown that electrides are suitable for achieving various topological semimetal phases [1]. In our presentation, we show that the apatite A₆B₄(SiO₄)₆, one of the one-dimensional electrides, realizes a higher-order topological insulator with 2/3-filled one-dimensional metallic hinge states. This is considered to be in the class of Cₙ-protected higher-order topological insulators proposed by Benalcazar et al. [2], but the hinge charge is different from that naively expected from their theory. This difference comes from the difference in the fundamental units constituting the crystal; the apatite crystal consists of triangular units, unlike hexagonal units assumed in Ref. [2]. We show how this difference affects topological properties of the system via crystal terminations.

*This work was supported by JSPS KAKENHI Grant Number 18H03678, and by the MEXT Elements Strategy Initiative to Form Core Research Center (TIES).
12:15PM G60.00004: Evidence of Higher Order Topology in WTe$_2$ from Josephson Coupling through Anisotropic Hinge States  YONG-BIN CHOI (Presenter), Department of Physics, POSTECH, Pohang, Republic Korea, YINGMING XIE, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China, CHUI-ZHEN CHEN, Institute for Advanced Study and School of Physical Science and Technology, Soochow University, Suzhou 215006, China, JINHO PARK, Department of Physics, POSTECH, Pohang, Republic Korea, SU-BEOM SONG, Department of Materials Science and Engineering, Pohang University of Science and Technology, Pohang, Republic of Korea, JIHO YOON, Max Plank Institute for Microstructure Physics, Halle (Saale), Germany, BUMJOON KIM, Department of Physics, POSTECH, Pohang, Republic Korea, TAKASHI TANIGUCHI, KENJI WATANABE, Research Center for Functional Materials, National Institute for Materials Science, Tsukuba, Ibaraki, Japan, HU-JONG LEE, Department of Physics, POSTECH, Pohang, Republic Korea, JONGHWAN KIM, Department of Materials Science and Engineering, Pohang University of Science and Technology, Pohang, Republic of Korea, KIN CHUNG FONG, Raytheon BBN Technologies, Quantum Information Processing Group, Cambridge, MA 02138, USA, MAZHAR ALI, Max Plank Institute for Microstructure Physics, Halle (Saale), Germany, KAM TUEN LAW, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China, GIL-HO LEE, Department of Physics, POSTECH, Pohang, Republic Korea — The noncentrosymmetric Td-WTe$_2$, previously known as a Type-II Weyl semimetal, is expected to have higher order topological phases with topologically protected, helical one-dimensional (1D) hinge states when their scarcely separated Weyl points get annihilated. However, the detection of these hinge states is difficult in the presence of the semimetallic behaviour of the bulk. Here, we spatially resolved the hinge states by analysing the magnetic field interference of supercurrent in Nb-WTe$_2$-Nb proximity Josephson junctions. The Josephson current along the $a$-axis of the WTe$_2$ crystal, but not along the $b$-axis, showed sharp enhancements at the edges of the junction; the amount of enhanced Josephson current was comparable to the upper limits of a single 1D conduction channel. Furthermore, the Josephson effect under microwave radiation, shows voltage doubling of Shapiro steps when Josephson current flows along the $a$-axis of WTe$_2$ crystal, which implies $4\pi$ periodicity of current phase relationship. Our experimental observations provide evidence of the higher order topological phase in WTe$_2$ and its corresponding anisotropic topological hinge states, in good agreement with theoretical calculations.

12:27PM G60.00005: Higher order topological insulators in anti-perovskites  YUAN FANG (Presenter), JENNIFER CANO, Stony Brook University — We prove that a family of anti-perovskite materials realize a higher order topological insulator (HOTI) phase, characterized by a previously introduced Z4 index. A tight binding model and a k.p model are used to capture the physics of the bulk, surface and hinge states of these anti-perovskites. A phase diagram of the Z4 index and weak topological invariant is obtained for the tight binding model. The mirror Chern number is also discussed. In order to reveal the gapless hinge states in the presence of mirror Chern surface states, several ways of opening the surface gap are proposed and confirmed by calculation, including cleaving the lattice to reveal a low-symmetry surface, building a heterostructure, and applying strain. Upon opening the surface gap, we are able to study the hinge states by computing the momentum space band structure and real space distribution of mid-gap states.
Transport evidence of triply degenerate nodal semimetal YRh$_6$Ge$_4$*

YANGLIN ZHU (Presenter), Department of Physics, Pennsylvania State University, XIN GUI, Department of Chemistry, Louisiana State University, YU WANG, Department of Physics, Pennsylvania State University, DAVID E GRAF, National High Magnetic Field Laboratory, WEIWEI XIE, Department of Chemistry, Louisiana State University, ZHIQIANG MAO, Department of Physics, Pennsylvania State University — Triply-degenerate nodal semimetal (TDNS) represents a new topological quantum state [1,2]. In this talk, we report our magnetotransport studies on YRh$_6$Ge$_4$, which was recently predicted to be a TDNS[3]. We find it exhibits remarkable signatures of a chiral anomaly, manifested by large negative longitudinal magnetoresistance, quadratic field dependence of magnetoconductance and planar Hall effect [4]. Furthermore, we have also observed Shubnikov-de Haas (SdH) quantum oscillations, the analyses of which reveals two point-like Fermi surfaces consistent with the calculated band structure; these pockets host nearly massless three-component fermions. These results suggest YRh$_6$Ge$_4$ may serve as a model system to probe the exotic properties of three-component fermions and understand their underlying physics.

*This work is supported by NSF under grants DMR 1917579 and 1832031.
12:51PM G60.00007: Cornering the zero mode: realization of an artificial electronic higher-order topological insulator*  MARLOU SLOT (Presenter), National Institute of Standards and Technology, SANDER KEMPKES, JETTE VAN DEN BROEKE, PIERRE CAPIOD, Utrecht University, VLADIMIR A BENALCAZAR, Pennsylvania State University, DARIO BERCIOUX, Donostia International Physics Center, DANIEL VANMAEELBERGH, CRISTIANE MORAIS SMITH, INGMAR SWART, Utrecht University — Quantum simulators are essential tools for understanding complex quantum materials. Platforms based on ultracold atoms in optical lattices and photonic devices have led the field so far, but the basis for electronic quantum simulators is now being developed. Here, we experimentally realize an electronic higher-order topological insulator (HOTI). More specifically, we create a breathing kagome lattice by manipulating carbon monoxide molecules on a Cu(111) surface using a scanning tunneling microscope [1]. We engineer alternating weak and strong bonds to show that a topological state emerges at the corner of the non-trivial configuration, but is absent in the trivial one. Different from conventional topological insulators, the topological state has two dimensions less than the bulk, denoting a HOTI. The corner mode is protected by a generalized chiral symmetry, leading to a particular robustness against perturbations. Our versatile approach to designing artificial lattices holds promise for investigating novel quantum phases of matter.

1:03PM G60.00008: Systematic investigation of physical properties of YbB$_{6\pm x}$ using the combinatorial approach*  SEUNGHUN LEE (Presenter), XIAOHANG ZHANG, NAILA AL HASAN, HUILONG HOU, University of Maryland, College Park, SUCHISMITA SARKER, APURVA MEHTA, SLAC National Accelerator Laboratory, RICHARD GREENE, ICHIRO TAKEUCHI, University of Maryland, College Park — Rare-earth boride systems have gained tremendous interest for exploring exotic and novel physical phenomena such as mixed valence states, heavy fermion, strong correlation and superconductivity. Since samarium hexaboride (SmB$_6$) has turned out to be a topological insulator, ytterbium boride (YbB$_x$) systems have been intensively studied as another possible topological insulator. However, the existence of the topologically protected surface states of YbB$_6$ is yet to be confirmed, and the origin of the quantum oscillations in Kondo insulator YbB$_{12}$ remains unresolved. We are systematically investigating the physical properties of YbB$_{6\pm x}$ depending on stoichiometry using the thin-film combinatorial approach. The composition spread YbB$_{6\pm x}$ thin films were fabricated by the co-sputtering of YbB$_6$ and B targets. The composition mapping of the spread films is performed using wavelength dispersive X-ray spectroscopy (WDS), and synchrotron x-ray diffraction measurements are employed for structural mapping analysis. We will discuss the electrical behavior of YbB$_{6\pm x}$ with the change in the valence state of Yb ion depending on the stoichiometry.

*This work was supported by AFOSR No. FA9550-14-10332.
1:15PM G60.00009: The fate of topological properties in U-based materials*  FREDERICO BENEDETTO SANTOS (Presenter), JOE D THOMPSON, ERIC BAUER, SEAN THOMAS, FILIP RONNING, PRISCILA ROSA, Los Alamos National Laboratory — Recent reports on CeSbTe show that Weyl and Dirac topological states can be tuned by low magnetic fields, which provide a promising route for investigating the interplay between magnetism and topology [1]. Here we aim at increasing the degree of correlations in this system by replacing Ce with U atoms. Though USbTe has been investigated previously [2,3], little is known about its putative topological properties. In this talk, I will discuss the growth of USbTe single crystals and their physical properties characterization via thermodynamic and electrical transport measurements at ambient pressure and under applied pressure.

*Work at Los Alamos was performed under the auspices of the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering.

1:27PM G60.00010: New kagome prototype materials: discovery of KV$_3$Sb$_5$, RbV$_3$Sb$_5$, CsV$_3$Sb$_5$*  BRENDEN ORTIZ (Presenter), University of California, Santa Barbara, LIDIA GOMES, University of Illinois at Urbana-Champaign, JENNIFER R MOREY, MICHAL J. WINIARSKI, Johns Hopkins University, MITCHELL BORDELON, University of California, Santa Barbara, JOHN S MANGUM, Colorado School of Mines, IAIN OSWALD, Colorado State University, JOSE RODRIGUEZ-RIVERA, NIST Center for Neutron Research, JAMES NEILSON, Colorado State University, STEPHEN WILSON, University of California, Santa Barbara, ELIF ERTEKIN, University of Illinois at Urbana-Champaign, TYREL MCQUEEN, Johns Hopkins University, ERIC TOBERER, Colorado School of Mines — With its unique and elegant structure, the kagome lattice is a key platform for the study of condensed matter physics. From quantum spin liquid candidates, topologically nontrivial phases, and Weyl semi-metal candidates, these materials are poised at the frontier of material science. The kagome metals, in particular, offer unique opportunities due to the delocalization of electrons and renormalization of the electronic and magnetic ground state. Recently we discovered a new class of kagome metals: KV$_3$Sb$_5$, RbV$_3$Sb$_5$, and CsV$_3$Sb$_5$, all of which crystallize in the P6/mmm space group and exhibit a structurally perfect kagome lattice of vanadium. Our work has indicated that these materials are prime candidates for correlated electron phenomenon (anomalous Hall, heavy fermion transport, etc.). Furthermore, the Fermi level is in close proximity to Dirac features, and we can demonstrate Fermi level tuning through deintercalation of the alkali metal. Our work indicates that KV$_3$Sb$_5$ and its cogeners are fruitful candidates for the exploration of exotic transport phenomena.

PbPd$_3$ has been reported to host an interesting band structure that includes a dispersionless branch along the Γ-X line that could result in a large DOS near the $E_F$ and Dirac-like surface states.[1] Previous results on the Fermi surface topography of PbPd$_3$ suggest that the $E_F$ is roughly 50 meV above the flat bands.[2] This results in the flat bands only having a weak effect on the bulk properties, while the impact of the Dirac cone at the Γ-point is limited due to it being several hundred meV above the $E_F$. In order to access the flat bands, we doped Au on the Pb site to lower the $E_F$. As a result, a significantly enhanced thermopower has been achieved. Furthermore, we performed magnetoresistance and torque magnetometry measurements in magnetic fields up to 45 T to reveal the change in the Fermi surface as a result of doping. We will discuss detailed results of the Fermi surface topology measurements on these doped series and prospects for tuning the $E_F$ in the opposite direction to meet the Dirac cone.

1:51PM G60.00012: The Bulk boundary Correspondence in 3d non-Hermitian Semimetals
ZHICHENG ZHANG (Presenter), ZHESEN YANG, JIANGPING HU, Chinese Academy of Sciences, Institute of Physics — Recently, both numerical and analytical methods are proposed to calculate the generalized Brillouin zone (GBZ) and explore the bulk-boundary correspondence in non-Hermitian systems. In this article, we apply these methods to the study of the bulk-boundary correspondence of non-Hermitian semimetal model. Concretely, we take two non-Hermitian semimetal models into account and assume open boundary condition in x, y, and z directions. In each case, we calculate the spectrums and GBZ with typical parameters and plot topological phase diagram with unit-circle Brillouin zone. We find that GBZ recovers the manifest consistency between OBC and PBC spectrums, and the topological phase diagram in x, y, and z direction open boundary condition is consistent with the projection of 3-dimensional (3d) topological phase diagram into corresponding direction. Besides, we compare the topological phase diagrams calculated with unit-circle Brillouin zone and GBZ, which clearly shows that GBZ recovers the bulk-boundary correspondence in non-Hermitian systems. The GBZ phase diagrams in x-direction and y-direction open boundary cases, there exist exceptional lines phases; and in z-direction open boundary case, we get the parameter space for topological nontrivial phase with winding number \( w = 1 \).

2:03PM G60.00013: Phonon Hall effect in nonmagnetic insulators
TAKUMA SAITO (Presenter), KOU MISAKI, HIROAKI ISHIZUKA, NAOTO NAGAOSA, Univ of Tokyo — Thermal Hall effect (THE), a phenomena in which the presence of magnetic field causes thermal current perpendicular to the temperature gradient, is a useful probe to detect current of charge-neutral particles in materials: excitation of spin or lattice motion. Recently, mechanisms of THE have been theoretically investigated to reveal how the charge-neutral particles are affected by magnetic moments or magnetic field. THE of phonons has been observed only in magnetic insulators [1], and previous studies have attributed the origin of THE to spin-phonon interaction, such as the Raman interaction [2] and magnon-phonon interaction [3]. In sharp contrast, our study shows that THE of phonon is possible even without magnetic moment. This is due to imperfect screening of magnetic field in crystals: negative charge of electrons and positive one of nuclei do not completely cancel each other when the correction beyond the adiabatic approximation is taken into account. For quantitative estimation, we calculated the THE in lattice models of band insulators.

Transport properties and flux pinning analysis of high-performance FeAs122 superconducting wires [Invited] YANWEI MA (Presenter), Institute of Electrical Engineering, Chinese Academy of Sciences — Iron-based superconductors (IBS), especially 122 type, are very promising candidates for high-field applications because of its ultra-high $H_{c2} > 70$ T at 20 K, low anisotropy ($g < 2$ for 122), and ease of fabrication. In recent years, tremendous progress has been made on the critical current density ($J_c$) of the 122-type IBS wires based on a powder-in-tube technique. Encouraging breakthroughs were made, including a high transport $J_c$ exceeding the practical level of $10^5$ A cm$^{-2}$ (at 4.2 K, 10 T), the first 100 meter-class wire and the first performance test of a 30 mm IBS inserted coil under a 24 T background field. More recently, the highest transport $J_c$ value has achieved 0.15 MA/cm$^2$ ($I_c = 437$ A) at 4.2 K and 10 T in densified and textured 122 tapes made by hot pressing. The transport $J_c$ measured at 4.2 K under high magnetic field of 27 T is still on the level of 55 kA/cm$^2$. Herein we compared the $T_c$ and $J_c$ distributions of the K-doped FeAs122 tapes by a calorimetric method. We found that hot-pressing provides a better environment for a complete chemical reaction and a more homogenous dopant distribution, which are beneficial to the global current of a superconductor. We further study the vortex dynamics of the hot-pressed high-$J_c$ tapes. We found that the magnetization relaxation rate below 10 K shows a temperature insensitive plateau with a value comparable to that of low temperature superconductors. Moreover, the relaxation rate below 20 K tends to saturate with the increasing field which is beneficial for high field application. We also highlight some remarkable advances relevant to practical applications, including mechanical strain properties, copper sheaths, multifilamentary fabrication, and superconducting joints.
Superconducting phase diagram of Ni-doped magnetically ordered superconductor RbEu(Fe\(_{1-x}\)Ni\(_x\))\(_4\)As\(_4\) for x ≤ 0.04 in pulsed fields up to 65 T* MATTHEW SMYLIE (Presenter), Hofstra University, KRISTIN WILLA, Karlsruhe Institute of Technology, YILMAZ SIMSEK, Sabanci University, JINKE BAO, Argonne National Laboratory, HENDRIK HEBBEKER, Hofstra University, WAI-KWONG KWOK, DUCK YOUNG CHUNG, Argonne National Laboratory, MERCOURI KANATZIDIS, Northwestern University, JOHN SINGLETON, FEDOR BALAKIREV, Los Alamos National Laboratory, ULRICH WELP, Argonne National Laboratory — The superconducting phase diagram of single-crystal RbEu(Fe\(_{1-x}\)Ni\(_x\))\(_4\)As\(_4\) for x = 0.02, 0.03, 0.04 has been measured in pulsed magnetic fields up to 65 T using a proximity diode oscillator technique. Doping lowers T\(_c\) and slightly lowers the superconducting anisotropy, but does not affect the Eu magnetic order. Upon doping, the curvature of phase boundaries for both H || ab and H || c remains remarkably consistent, indicating that the suppression of T\(_c\) is doping driven, not disorder driven. As in the parent compound, Pauli limiting dominates H\(_{c2}\)\(_{ab}\), whereas orbital limiting dominates H\(_{c2}\)\(_c\). The resultant high Maki parameter \(\alpha\) for H || ab is consistent with a possible FFLO state at low temperatures, but none is seen in the accessible field range.

ReEuFe₄As₄ is a Fe-base superconductor with a high transition temperature of $T_c \sim 37$ K that enters into a magnetic state at 15 K in which Eu-4f moments are helically ordered. In this state, in-plane ferromagnetically ordered Eu-planes undergo 90 deg rotation between layers resulting in a commensurate helix with a period of 4 c-axis lattice constant. This structure is easily polarized in fields of the order of several kOe resulting in a field-induced ferromagnet with a moment of 7 $\mu_B$/ (unit cell) coexisting with superconductivity. Nevertheless, most measurements to date have yielded no or only very weak coupling between superconductivity and magnetism. Using specific heat measurements in fields up to 14 T, we show that the $H_{c2}$-line exhibits clear downwards curvature in a temperature range close to $T_c$ where Ginzburg-Landau theory applies, amounting to a shift by $\delta T_c \sim 0.4$ K in 14 T $\parallel$ c. This effect can be captured quantitatively in a model in which the exchange fields from the field-induced polarization of the Eu-moments renormalize $T_c(H)$.

* The work at Argonne National Laboratory was supported by the U.S. Department of Energy, Office of Science, Materials Sciences and Engineering Division. The PPMS used for specific heat measurements was funded by NSF MRI grant 1828387.
12:15PM G61.00004: Angular dependent studies of vortex pinning and dynamics in RbEuFe₄As₄ single crystals with columnar defects*  IVAN NEKRASHEVICH (Presenter), Los Alamos Natl Lab, MATTHEW SMYLIE, Dept. of Physics and Astronomy, Hofstra University, ULRICH WELP, WAI-KWONG KWOK, ALEXEI KOSHELEV, JIN-KE BAO, DUCK YOUNG CHUNG, MERCOURI KANATZIDIS, Materials Science Division, Argonne National Laboratory, LEONARDO CIVALE, Los Alamos Natl Lab — We performed studies of vortex pinning and dynamics in RbEuFe₄As₄ single crystals with different densities and orientations of aligned columnar defects (CDs) introduced by heavy ion irradiation, as a function of temperature (T) and magnetic field strength (H) and orientation (Θ). Pristine crystals have a superconducting transition temperature \( T_c \sim 37K \) and a magnetic ordering transition of the Eu at \( T_m \sim 15K \), neither of which is changed by the irradiations. We developed a model to account for the modifications to the vortex critical state produced by the magnetic moments. Irradiated crystals exhibit large critical current densities \( J_c \) and a lock-in phase (where vortices remain fully trapped into the CDs even if \( H \) is tilted away from them), which is the fingerprint of correlated pinning. For large CDs densities (e.g. matching field \( B_\Phi \sim 10T \)) the lock-in phase spans an unusually large angular range and extends to fields above 2T. This allows us to investigate the angular variations of \( J_c \) and the creep rates associated with the expansion of half-loops and double-kinks inside the lock-in region, due to the changes in the pinning energy arising from the \(-B\cdot H/4\pi\) term in the free energy.

*Work funded by US DOE, Office of Basic Energy Sciences, Materials Sciences and Engineering Division.

12:27PM G61.00005: Fermi Surface Folding and Surface Reconstruction in an Iron-Based Superconductor CaKFe₄As₄*  YONGQING CAI (Presenter), HUAN YANG, TAO XIE, CONG LI, YU XU, DINGSONG WU, GUODONG LIU, HUIQIAN LUO, H.-J. GAO, LIN ZHAO, XINGJIANG ZHOU, Chinese Academy of Sciences, Institute of Physics — High resolution angle resolved photoemission spectroscopy and scanning tunneling microscopy were carried on the CaKFe₄As₄ to study its electronic structure. CaKFe₄As₄ consists of parent compound CaFe₂As₂ and heavily hole doped KFe₂As₂ but with a high \( T_C \) of 35K. We found three hole-like pockets at the Brillouin zone center and two electron-like pockets around the Brillouin zone corner. We also discovered a large hole pocket around the Brillouin zone corner which has the same size as the outmost hole pocket at the Brillouin center. Using scanning tunneling microscopy, we determine that there exists × reconstruction in CaKFe₄As₄, which will lead to the folding of the hole pocket from Brillouin zone center to Brillouin zone corner. The implication of these observations related to other iron-based superconductors will be discussed.

**12:39PM G61.00006: Scattering studies of the nature of long-range magnetic order coexisting with superconductivity in single-crystal RbEuFe$_4$As$_4^*$**  
ZAHIRUL ISLAM (Presenter), Argonne Natl Lab, OMAR CHMAISSEM, Northern Illinois University, ULRICH WELP, JONG WOO KIM, Argonne Natl Lab, HUIBO CAO, Oak Ridge Natl Lab, ALEXEI KOSELEV, Argonne Natl Lab, KRISTIN WILLA, Karlsruhe Institute of Technology, MATTHEW SMYLIE, Hofstra University, ZHU DIAO, Halmstad University, ANDREAS RYDH, Stockholm University, JINKE BAO, DUCK YOUNG CHUNG, Argonne Natl Lab, MERCOURI KANATZIDIS, Northwestern University, WAI-KWONG KWOK, STEPHAN ROSENKRANZ, Argonne Natl Lab — We present magnetic long-range order studied by x-ray scattering and magnetic neutron diffraction (MND) on a single crystal RbEuFe$_4$As$_4$ (RbEu1144) superconductor. In tetragonal RbEu1144 superconductivity (SC) appears at ~37 K followed by an antiferromagnetic (AFM) transition at $T_N$ ~15 K. Our diffraction studies revealed a long-range, fully coherent, and 3D ordered magnetic phase characterized by a single wavevector, $q=(0,0,1/4)$, which indicates a 4-unit-cell magnetic periodicity along the 4-fold $c$ axis. High-resolution x-ray scattering did not find any detectable structural distortions (e.g. orthorhombic) at low temperatures. Element-selective x-ray resonant scattering (XRS) and MND measurements indicated a helical magnetic order of full Eu$^{2+}$ moments locked into the $ab$ plane, without the presence of any ferromagnetism (FM). The use of charge-magnetic interference phenomena in XRS for measuring hysteresis and determining trapped magnetic field value is presented.

**12:51PM G61.00007: Mechanism of helical interlayer magnetic structure in RbEuFe$_4$As$_4^*$**  
ALEXEI KOSELEV (Presenter), Argonne Natl Lab — Motivated by the discovery of helical magnetic structure in RbEuFe$_4$As$_4$ [1], we study interlayer ordering of magnetic moments in a material composed of spatially-separated superconducting and ferromagnetic layers [2]. We consider the interplay between the normal and superconducting indirect exchange interaction mediated by tunneling between the conducting layers. The normal interlayer interaction can be related with the 2D density of states of an isolated layer. For shallow bands, such interaction is ferromagnetic and short-range. On the other hand, the superconducting contribution always gives antiferromagnetic interaction and extends over several layers if the interlayer hopping energy exceeds the superconducting gap. The frustration between the normal and superconducting parts may lead to a spiral magnetic configuration. The 90$^\circ$ angle between the neighboring-layers moments observed in RbEuFe$_4$As$_4$ is caused by four-fold in-plane anisotropy. This model explains a physical origin of the magnetic spiral in RbEuFe$_4$As$_4$.

1:03PM G61.00008: Competition between spin-vortex crystal and superconductivity in Ni-doped CaKFe$_4$As$_4$*  ANDREAS KREYSSIG (Presenter), JOHN WILDE, Ames Laboratory, Iowa State University, Dept. of Physics and Astronomy, Ames, ANNA E. BÖHMER, Ames Laboratory, Iowa State University, Ames; Karlsruhe Institute of Technology, Karlsruhe, WEI TIAN, Oak Ridge National Laboratory, Oak Ridge, WILLIAM MEIER, Ames Laboratory, Iowa State University, Ames; Oak Ridge National Laboratory, Oak Ridge, BING LI, BENJAMIN G. UELAND, MINGYU XU, SERGEY L. BUD'KO, PAUL C. CANFIELD, ROBERT MCQUEENEY, ALAN I. GOLDMAN, Ames Laboratory, Iowa State University, Dept. of Physics and Astronomy, Ames — CaKFe$_4$As$_4$ is a member of the iron arsenide superconductors in which partial substitution of Ni for Fe shifts the ground state from superconducting to antiferromagnetically (AFM) ordered. Employing neutron diffraction we determined that the AFM order is a non-collinear, commensurate structure with a hedgehog spin-vortex crystal (SVC) arrangement in the Fe planes and a simple AFM stacking perpendicular to them. The long-range SVC order coexists with superconductivity, however, similar to the doped 122 compounds with collinear stripe AFM, the ordered magnetic moment is gradually suppressed as the superconducting order parameter develops. Almost complete suppression of the AFM order is observed in a sample close to the critical Ni concentration, resulting in a back-bending of the AFM-transition-temperature phase line as a function of concentration. This supports the notion that both collinear and non-collinear magnetism as well as superconductivity compete for the same Fermi-surface nested electrons in the iron arsenide superconductors.

1:15PM G61.00009: Magnetic susceptibility of realistic superconducting samples* RUSLAN PROZOROV (Presenter), MAKARIY A TANATAR, NAUFER M NUSRAN, KYUIL CHO, KAMAL JOSHI, SUNIL GHIMIRE, Ames Laboratory — Finite element numerical exploration of the Meissner-London equations was performed for realistic three-dimensional (3D) superconducting samples of non-ellipsoidal shape and, also, having internal textures. The goal was to establish the connection between the effective finite-size magnetic susceptibility, geometric parameters of the model and the intrinsic parameters such as London penetration depth. Theoretical results are compared with the experiments where the total magnetic susceptibility was measured using tunnel-diode resonator and local first critical field was measured using NV-centers in diamond optical magnetometry. The observed differences are attributed to the specific morphological features of iron-based superconductors and high-$T_c$ cuprates.

*This work was supported by the US DOE, Office of Science, BES Materials Science and Engineering Division under contract # DE-AC02-07CH11358.
Cooperative response of the magnetic and superconducting subsystems in magnetic superconductor RbEuFe4As4* VITALII VLASKO-VLASOV (Presenter), ULRICH WELP, ALEXEI KOSHELEV, Argonne Natl Lab, MATTHEW SMYLIE, Hofstra University, JINKE BAO, DUCK YOUNG CHUNG, Argonne Natl Lab, MERCOURI KANATZIDIS, Northwestern University, WAI-KWONG KWOK, Argonne Natl Lab — We present magneto-optics and magnetization based studies of the magnetic flux evolution in single crystals of the magnetic superconductor RbEuFe4As4 during field cooling and warming, and magnetic field cycling at temperatures above and below the magnetic transition point, Tm. The vortex patterns emerging at T below and ~Tm on different crystal facets in the fields of different orientations, reveal a peculiar magnetization process, where the magnetic subsystem serves as an internal magnetic flux pump while the superconducting subsystem controls the entry of magnetic flux quanta into the bulk. The interplay of magnetic susceptibility amplifying the magnetic induction and vortex pinning attenuating the magnetic flux entry, results in a field and temperature dependent critical state that mimics a paramagnetic Meissner effect. The observed anisotropic vortex dynamics is associated with a peculiar fine scale Eu-spin helical structure modified by the vortex field and resulting in a nontrivial spatial current distribution, which yields a self-consistent inhomogeneous enhancement of the sample magnetization.

*The work was supported by the U.S. Department of Energy, Office of Science, Materials Sciences and Engineering Division.

Temperature dependent resistivity in hole-doped Ba1−xKxFe2As2 subject to electron irradiation* MAKARIY TANATAR (Presenter), YONG LIU, T. A. LOGRASSO, RUSLAN PROZOROV, Ames Lab, MARCIN KONCZYKOWSKI, OLIVIE CAVANI, LSI, Ecole Polytechnique — Temperature dependence of in-plane and inter-plane electrical resistivity was studied in single crystals of hole doped iron based superconductor Ba1−xKxFe2As2 (0 ≤ x ≤ 1). Low temperature (20 K) irradiation with relativistic 2.5 MeV electrons was used to control residual resistivity of the samples. Matthiessen rule is found to be universally violated for all compositions and for both current flow directions. This is in stark contrast with electron doped Ba(Fe1−xCox)2As2 [1] and iso-electron substituted BaFe2(As1−xPx)2 [2]. Possible reasons for Matthiessen rule violation are discussed.

*This work was supported by the US DOE, Office of Science, BES Materials Science and Engineering Division under contract # DE-AC02-07CH11358.
1:51PM G61.00012: Strain effect on the superconductivity of FeSe$_{0.5}$Te$_{0.5}$ thin films induced by mica substrate
YE GAO (Presenter), CHENGuang MEI, MIAO MENG, XI ZHANG, YONGGuANG ZHAO, Tsinghua University — Iron-based superconductors have attracted much attention because of their promising prospects in both applied and fundamental research. Iron chalcogenide superconductors, which have the simplest structure, play an important role in this field. It has been shown that pressure or strain has remarkable influence on their superconducting transition temperatures ($T_C$) [1, 2]. To further explore the strain effect, we grow epitaxial FeSe$_{0.5}$Te$_{0.5}$ (FST) thin films on muscovite mica substrates by pulsed laser deposition, because different strains can be induced by bending mica owing to the flexibility of mica after mechanical exfoliation [3]. It is shown that $T_C$ value of FST increases under compressive strain while decreases under tensile strain. It is also indicated that the relative orientations of electrical current and strain are important in the change of transport property. The results are discussed by considering different contributions. This work is helpful to understand superconducting mechanism of iron chalcogenide superconductors, and shows a great potential for novel applications with flexible superconductors.

2:03PM G61.00013: Spontaneous Nernst Effect in an Iron-based Topological Superconductor Fe$_{1+y}$Te$_{1-x}$Se$_x$  
LU CHEN (Presenter), ZIJI XIANG, COLIN B TINSMAN, Univ of Michigan - Ann Arbor, GENDA GU, Brookhaven National Laboratories, LU LI, Univ of Michigan - Ann Arbor — We report on a study of Nernst effect in an iron-based superconductor Fe$_{1+y}$Te$_{1-x}$Se$_x$. We observe a zero-field Nernst effect that appears around the superconducting transition temperature $T_C$. This spontaneous Nernst signal does not follow the temperature and field dependence of the thermal power and occur only in the temperature range near $T_C$ where the superconducting fluctuation is strong and vortex liquid is robust. This intrinsic spontaneous Nernst signal indicates the violation of time reversal symmetry (TRS) in the superconducting state. The TRS in Fe$_{1+y}$Te$_{1-x}$Se$_x$ may be broken by pinning flux introduced by the interstitial iron impurity. To further understand the role of excess Fe atoms, we study a series of Fe$_{1+y}$Te$_{1-x}$Se$_x$ single crystals that have different $T_c$ and different levels of excess Fe concentrations and demonstrate how they affect the spontaneous Nernst effect signal.

Session G62 DMP: Nanostructures and Metamaterials V  Mile High Ballroom 4C - Xiaobo Yin, Lawrence Berkeley National Laboratory
11:15AM G62.00001: Soft porous polymer materials, a new range of acoustic metasurfaces*

KATERINA KAMPIOTI (Presenter), JACQUES LENG, CNRS Bordeaux — In 2011 a new range of 2D materials, widely known as metasurfaces, has emerged. These planar metamaterials of subwavelength thicknesses, capable of wave front shaping, consist of a single or several layers of artificial structure1.

In general, metasurfaces are engineered by assembling arrays of deep sub wavelength building blocks. Here, we present a bottom-up approach which is based on soft-porous material: the dependence of the refractive index of soft porous polymer materials with their porosity enable us to fabricate acoustic gradient-index (GRIN) metasurfaces1. Yet, their fabrication requires photo-polymerization of the thin film, which is made difficult by the presence of porogenic agents that scatter light. We will present a rational approach to understand the coupling between photo-chemistry and light scattering (in scattering media), and we will illustrate how the use of grayscale lithography facilitates the generation of this high precision microstructures.

*This work was funded and performed within the project BRENNUS ANR-15-CE08-0024.

11:27AM G62.00002: Self-Assembly of Poly(ethylene glycol)-Functionalized Gold Nanorods at the Vapor/Liquid Interface*

HYEONG JIN KIM (Presenter), WENJIE WANG, Ames laboratory, Iowa State University, WEI BU, ChemCARS, The University of Chicago, SURYA MALLAPRAGADA, DAVID VAKNIN, Ames laboratory, Iowa State University — Using surface sensitive synchrotron X-ray diffraction, we report on the self-assembly of gold nanorods (AuNRs) into 2D films at the vapor/liquid interface. The films are facilitated by grafting the AuNRs with poly(ethylene glycol) (PEG). Grazing incidence small angle X-ray scattering (GISAXS) and specular X-ray reflectivity (XRR), show that PEG-AuNRs in aqueous suspensions migrate to the vapor/liquid interface in the presence of salt, forming a uniform monolayer with planar-to-surface orientation. Furthermore, the 2D assembled PEG functionalized AuNRs exhibit short range order into rectangular symmetry with side-by-side and tail-to-tail nearest-neighbor packing. The effect of PEG chain length and salt concentration on the 2D assembly are also reported.

11:39AM G62.00003: Temperature-induced self-assembly and crystallization of gold nanorods*  DAVID VAKNIN (Presenter), HYEONG JIN KIM, WENJIE WANG, ALEX TRAVERSET, SURYA MALLAPRAGADA, Ames Laboratory, Iowa State University — We report on temperature-induced and improved assembly and crystallization of gold nanorods (AuNRs) that are grafted with poly(ethylene glycol) (PEG) in electrolytic suspensions. Small angle X-ray scattering (SAXS) reveals that elevating the temperature of dispersed PEG-AuNRs suspensions in the presence of electrolytes or poly-electrolytes spontaneously induces the assembly of the AuNRs into hexagonal superlattices. Surprisingly, we find that the lattice constant of the crystalline AuNRs significantly decreases and crystal quality improves by increasing the temperature of the suspensions. Implications of the results for engineering new nanomaterials are discussed.

11:51AM G62.00004: Laser-written nanograting deep inside silicon*  AQIQ ISHRAQ (Presenter), RANA ASGARI SABET, ONUR TOKEL, UNAM - National Nanotechnology Research Center, Bilkent University — Functional optical elements fabricated on the surface of silicon (Si) constitute fundamental building blocks of Si-photonics. For fabrication of these elements, generally conventional lithography and etching techniques are used. We recently demonstrated a laser-writing method that enables direct creation of buried or “in-chip” optical elements inside the wafer [1]. This direct laser-writing method had enabled 3D optical elements at 1-µm resolution [1]. Here, we expand the technique for demonstrating the first in-chip nanogratings crated in Si, realized without damaging the wafer surface. In order to achieve this, we exploit the ‘non-diffracting’ nature of Bessel beams, and infrared laser pulses of ~5 ns, 1.55 µm where Si is transparent. The crystal structure is modified in the form of periodic rod-like structures with structure-widths 250 nm to 1-micrometer, resulting in grating efficiencies up to 45%. These in-chip optical elements constitute the first examples of a larger class of emerging in-chip nano-photonic components, that can potentially lead to novel infrared elements at the nanoscale.

* Bilim Akademisi (BAGEP Award)
12:03PM G62.00005: Large Area Superhydrophilic Silicon Surface Texturing using Nanosecond Laser Pulses  
NANCY VERMA (Presenter), Light and Matter Physics Department, Raman Research Institute, Bengaluru, India, K. K. ANOOP, Department of Physics, Cochin University of Science and Technology, Cochin, India, PRIYA DOMINIC, REJI PHILIP, Light and Matter Physics Department, Raman Research Institute, Bengaluru, India — We report experimental investigations of large area laser micro/nano texturing of silicon (100) targets by Nd: YAG laser pulses (λ=532 nm, τ =7 ns) addressing the wetting behavior of processed silicon surface. In particular, ns laser surface processing is used to develop hierarchical surface structures by the line scanning method to create parallel micro-channels with proper overlap between the lines at different laser pulse fluence ranging from 2 J/cm$^2$ to 4 J/cm$^2$. We observe that the bottom of craters formed due to single and multipulse laser irradiations are rather flat, but some concentric nano-ripple features are present along the rim of the craters, resulting in the formation of multiscale surface morphology. The topography of the samples is investigated using AFM and SEM, whereas the wetting property is measured through sessile drop contact angle measurements. The combination of microscale channels written by parallel line scan, with self-organized surface patterns and random nanoparticles decoration, formed on the surface allow developing highly hydrophilic silicon surfaces with contact angle values reaching around 5°, presenting potential interest for superwetting applications.

12:15PM G62.00006: Growth Kinetics of Metal Nanowires and Nanoplates*  
KRISTEN FICHTHORN (Presenter), ZIHAO CHEN, JUNSEOK KIM, Pennsylvania State University — Metal nanocrystals have gained tremendous attention due to their superior performance in various applications, ranging from selective catalysis to electronic devices to plasmonic applications. For these and many other applications, the properties of the nanocrystals are highly sensitive to their shape. However, it remains a challenge to achieve high shape selectivity in solution-phase syntheses. I will discuss our efforts to understand the growth of Cu and Ag nanocubes, nanowires and nanoplates, which is facilitated by the inclusion of halide ions (chloride, bromide, and iodide) in the synthesis protocol. We use ab initio thermodynamics based on quantum density-functional theory (DFT) to demonstrate how these halides create thermodynamic driving forces for cubes, plates and wires, by selectively altering surface energies. Using a combination of DFT and the theory of absorbing Markov chains, we demonstrate how halides affect surface diffusion and interfacet transport to drive the growth of particular nanoshapes in the presence of halide. Our results agree with experiment and indicate a promising way to exact control over nanocrystal synthesis.

Molecular dynamics simulation of silicon nanowires with oxide layers under uniaxial tension

WENTING XU (Presenter), WOO KYUN KIM, Univ of Cincinnati — The size-dependent brittle-to-ductile transition (BDT) of silicon is an important scientific topic, but its underlying mechanism is still unclear. Silicon nanostructures such as nanowires have been widely used in electronics and optoelectronics applications and have also been used to study the BDT phenomenon of silicon in both experiments and simulations. While silicon is spontaneously oxidized when exposed to air, most of the previous simulation studies have neglected the effect of oxide layers on BDT. In this work, we employ the molecular dynamics (MD) simulation method to study the influence of oxide layers on the BDT of silicon nanowires under uniaxial tension loading. The oxide layers are created by inserting oxygen atoms into the Si-Si bonds from the nanowire surface and several key factors such as nanowire diameter, thickness of oxide layers, temperature, and strain rate are considered. The MD simulation results reveal the effect of oxide layers on the plastic deformation of silicon nanowires and elucidate its atomic-scale mechanisms.

Porous Silica Cluster Collision Molecular Dynamics

ERIC SWITZER (Presenter), ANIKET BHATTACHARYA, Univ of Central Florida — Silica nanoparticles are theorized to exist in the interstellar medium, where collision velocities range over several orders of magnitude. We report molecular dynamics simulation studies of the coalescence of small (approx. 2 nm) porous silica clusters with each other for a range of velocities and initial cluster porosities. Our use of the ReaxFF bond-order potential allows us to account for bond dynamics during the collision. We vary cluster porosity through the random removal of silica base units during the cluster formation stage and monitor post-collision structural dynamics. We compare both the pair correlation function and structure factors of prepared porous clusters as verification of our preparation method. We use simulation data to study the evolution of post-collision cluster morphology characterized in terms of final porosities and fractal dimensions as a function of the initial range of porosities and velocities. We compare our results with similar studies using different potentials during collision processes.
12:51PM G62.00009: Granular aluminum meandered superinductors for quantum circuits

PLAMEN KAMENOV (Presenter), WEN-SEN LU, KONSTANTIN KALASHNIKOV, THOMAS J DINAPOLI, Rutgers University, New Brunswick, MATTHEW T BELL, University of Massachusetts, Boston, MICHAEL GERSHENSON, Rutgers University, New Brunswick — We report on the optimization, fabrication, and characterization of superinductors made of meandered nanowires of strongly disordered (granular) Aluminum [1]. Superinductors are essential for numerous superconducting quantum circuits operating at millikelvin temperatures. We succeeded in increasing the self-resonance frequency of superinductors by the optimization of its in-plane dimensions. These compact superinductors are beneficial for a wide range of applications, from superconducting circuits for quantum computing to microwave elements of cryogenic parametric amplifiers and kinetic-inductance photon detectors. We have also demonstrated that the superinductors based on granular Aluminum films can be integrated in “hybrid” superconducting circuits containing conventional Al-Al2O3-Al Josephson junctions.

1:03PM G62.00010: Characterization of Spin-Thermal Environment Interaction Leading to Nuclear Quadrupolar Spin Relaxation

SANGHAMITRA NEOGI (Presenter), MANOJ SETTIPALLI, University of Colorado, Boulder — The control of spin dynamics at the nanoscale is crucial for quantum technologies based on spin qubits. Quadrupolar nuclei with spin > ½ facilitates creation of N-qubit systems, the representation of many qubits with one nuclear species. Additionally, nuclei with strong quadrupole moments can be used to perform QIP with NQR. However, the strong quadrupole couplings lead to faster spin relaxation and stronger dissipation due to spin-environment interaction. It is crucial to analyze the effect of local environment fluctuations on spin-environment relaxation (SER) to correctly predict the evolution of the qubits implemented by the quadrupolar spins. The prediction of quadrupolar relaxation time (T1) in alkali halides improved considerably due to the inclusion of realistic phonon density of states, over approximate phonon dispersions. However, the predicted T1 is still off by an order of magnitude compared to measured data. Here, we extend the formulation by incorporating the full dispersion relations of thermal phonons to describe T1. Our study provides a framework to characterize the thermal noise affecting the nuclei spin qubits. We anticipate that this work will lead to tailoring the relaxation time by controlling phononic environment of the spin qubits.
1:15PM G62.00011: Spin transport in ferromagnet-InSb nanowire quantum devices

ZEDONG YANG (Presenter), BRETT HEISCHMIDT, School of Physics and Astronomy, University of Minnesota, SASA GAZIBEGOVIC, GHADA BADAWY, DIANA CAR, Eindhoven University of Technology, PAUL CROWELL, School of Physics and Astronomy, University of Minnesota, ERIK BAKKERS, Eindhoven University of Technology, VLAD PRIBIAG, School of Physics and Astronomy, University of Minnesota — Semiconductor nanowires (NWs) such as InSb are a leading platform for realizing future Majorana zero modes based on quantum computing\(^1\). However, the appliance of external magnetic fields can suppress the superconductivity and place geometric restrictions on the device. These challenges can be circumvented by integrating magnetic elements with the NWs. In our experiments, by fabrication ferromagnetic contacts, we investigate spin transport across InSb NWs in a quasi-1D ballistic regime\(^2\). Hysteretic magnetoconductance can be observed proving spin-polarized transport across the NWs. Moreover, we show that electrostatic gating tunes the observed hysteretic signal and also reveals a transport regime where the device acts as a spin filter.

1:27PM G62.00012: Optical Properties of Monolayer Bismuthene under Electric Field based on First-principles Calculations

WEI CHIEH LIU (Presenter), LIANGLIANG XU, MING-CHIEH LIN, Department of Electrical and Biomedical Engineering, Hanyang University, TSAN-CHUEN LEUNG, Department of Physics, National Chung Cheng University, HUA-YI HSU, Department of Mechanical Engineering, National Taipei University of Technology — Monolayer bismuthene has extraordinary optoelectronic, catalytic, and biocompatible properties, and potential as a 2D topological insulator. When monolayer bismuthene deposited on the surface of the object to form sufficiently thin, there is a stable form of a low buckling hexagonal structure. If the thickness of the crucible becomes thinner than the Fermi wavelength, there may be a transition from a semimetal to a semiconductor due to the quantum confinement effect. So this could be a promising low-dimensional thermoelectric material. The monolayer bismuthene is a p-type semiconductor, but the hole concentration arising from the intrinsic defects is very low and hard to control. It is found that the optical properties can be changed dramatically by applying external electric field. In this work, the energy band structure, density of states, and optical constants of bismuthene have been calculated using the first-principles calculations based on density functional theory (DFT). With applying an electric field, the optical properties of bismuthene are determined and compared to those calculated from the tight-binding model. The controlled optical properties of monolayer bismuthene may have some applications in optoelectronics, either combined with other 2D or topological materials.
1:39PM G62.00013: Shadowing of epitaxial superconductors on selectively grown in-plane semiconductor wires for advanced quantum devices  
JOON SUE LEE (Presenter), University of Tennessee Knoxville, MIHIR PENDHARKAR, CONNOR DEMPSEY, SUKGEUN CHOI, ARANYA GOSWAMI, University of California Santa Barbara, HAO WU, PO ZHANG, University of Pittsburgh, ROY OP HET VELD, ERIK BAKKERS, Eindhoven University of Technology, SERGEY M FROLOV, University of Pittsburgh, CHRIS J PALMSTROM, University of California Santa Barbara — In superconductor-semiconductor systems, a clean interface between superconductor and semiconductor is crucial for quantum transport studies. Advances in epitaxial Al growth on low-dimensional semiconductors have resulted in enhanced features of superconducting proximity effect. In addition, development of clean junctions by in-situ shadowing has led to further improvement of superconducting features in 1D nanowire-based systems. Here we demonstrate a shadowing scheme of epitaxial superconductors on in-plane quantum wires by selective-area growth. Shadow wall structures are pre-fabricated next to wire-shape trenches. After epitaxial growth of semiconductor wires on the trenches, Al deposition is carried out at an angle between 40 and 60 degrees from the normal direction of the substrate. The shadowing of Al results in clean Al-semiconductor junctions based on the shape of the shadow wall structures. This shadow scheme can be applied to any selective-area growth wires by various techniques such as molecular beam epitaxy, chemical beam epitaxy, and metalorganic vaporphase epitaxy. We further discuss transport studies in devices prepared by this scheme as well as deposition of another superconductor with a higher superconducting transition temperature.

1:51PM G62.00014: Synthetic Weyl Points and Chiral Anomaly in Majorana Devices  
PANAGIOTIS KOTETES (Presenter), Institute of Theoretical Physics, Chinese Academy of Sciences, MARIA TERESA MERCALDO, University of Salerno, MARIO CUOCO, CNR-SPIN — We demonstrate how to design various nonstandard types of Andreev-bound-state (ABS) dispersions, via a composite construction relying on Majorana bound states (MBSs). Here, the MBSs appear at the interface of a Josephson junction consisting of two topological superconductors (TSCs). Each TSC harbors multiple MBSs per edge by virtue of a chiral or unitary symmetry. We find that, while the ABS dispersions are $2\pi$ periodic, they still contain multiple crossings which are protected by the conservation of fermion parity. A single junction with four interface MBSs and all MBS couplings fully controllable, or networks of such coupled junctions with partial coupling tunability, open the door for topological band structures with Weyl points or nodes in synthetic dimensions, which in turn allow for fermion-parity (FP) pumping with a cycle set by the ABS-dispersion details. In fact, in the case of nodes, the FP pumping is a manifestation of chiral anomaly in 2D synthetic spacetime. The possible experimental demonstration of ABS engineering in these devices further promises to unveil new paths for the detection of MBSs and higher-dimensional chiral anomaly. 

Tuesday, March 3, 2020 11:15 AM - 2:15 PM

Session G63 DMP DCMP FIAP: Defects in Gallium Oxide and Nitride  
High Ballroom 4D - Anderson Janotti, University of Delaware - Tag(s): Focus
Gallium oxide is an emerging ultra-wide bandgap semiconductor that holds enormous promise for devices needed to operate in extreme conditions, including high electric fields, high temperatures and radiation environments. Attributes such as its ~ 4.8 eV bandgap, ease of n-type doping, ability to synthesize AlGaO alloys to enable heterostructure devices, availability of melt-grown large area Ga2O3 substrates, and device figures of merit that theoretically exceed more mature wide bandgap technologies based on SiC and GaN, all contribute to rapid acceleration of research in this area. To date, Ga2O3 materials and devices are being grown using a wide range of epitaxial methods, and identifying point defects that are associated with growth conditions, and discriminating between impurity and native physical sources are key to guiding the advancement of material quality so that Ga2O3 can reach its ultimate properties desired for applications in RF power electronics and UV optoelectronics. This presentation focuses on the ongoing investigation of defect states in the Ga2O3 bandgap using a range of defect spectroscopy methods that enable comprehensive characterization of deep level defects across the entire ~ 4.8 eV bandgap. Deep level optical spectroscopy, deep level transient (thermal) spectroscopy and admittance spectroscopy are applied to Ga2O3 materials and devices grown by MBE, MOCVD, LPCVD and EFG methods to enable a quantitative comparison of how defect introduction varies with growth method. High energy particle radiation is used to distinguish native from impurity-based defect states provides further differentiation regarding physical sources. Identification of which defects contribute to important properties for device transport, such as carrier compenstation and electron mobility, is discussed.

*This work is sponsored by the Defense Threat Reduction Agency (DTRA HDTRA1-17-10034) and the Air Force Office of Scientific Research (FA9550-18-1-0059 and FA9550-18-1-0479).
11:51AM G63.00002: Ab initio studies on segregation of n-type dopants and vacancies near beta-Ga2O3(010) surface  JINGYANG WANG (Presenter), Materials Science and Engineering, Stanford University, PAULETTE CLANCY, Chemical and Biomolecular Engineering, Johns Hopkins University — Beta-Ga2O3 is a wide-bandgap semiconductor with important electronic and optoelectronic applications. It has been observed that upon extended period of thermal annealing, certain types of n-type dopants such as Sn show strong tendency of segregation towards Ga2O3 surfaces, even forming a secondary SnO2 phase. Using density functional theory, we conducted a comprehensive study on the thermodynamic preference of common n-type dopants (Si_Ga, Ge_Ga, Sn_Ga) and intrinsic defects (V_Ga, V_O) both near the (010)-surface and in the bulk of Ga2O3. The key findings are: (1) in bulk Ga2O3, Si prefers to occupy tetrahedral over octahedral Ga site (by -0.60 eV), Sn shows the opposite preference (by -0.90 eV), and Ge have almost equal preference on either Ga site; (2) Si and Ge shows weaker likelihood of segregation towards Ga2O3(010) surface (-0.14 eV for Si, -0.11 eV for Ge) than Sn (-0.25 eV), while both V_Ga and V_O assume strong tendency of segregation (< -0.4 eV); (3) all dopant species (Si, Ge, Sn) show significantly decreased (increased) segregation energy with the presence of surface V_Ga (V_O); (4) co-doping with Si or Ge in the second-nearest-neighbor configuration can raise the segregation energy of Sn. The implications for experimental processing conditions will be discussed.

12:03PM G63.00003: Electronic properties of the Ga2O3-Fe2O3 system  SHOAIB KHALID (Presenter), Department of Physics and Astronomy, University of Delaware, FERNANDO SABINO, ANDERSON JANOTTI, Department of Material Science and Engineering, University of Delaware — Fe2O3 has attracted a lot of interest due to its interesting electronic, chemical and magnetic properties, with applications in photoelectrochemical cells, gas sensor, and Li ion batteries. It is readily available as one of the most abundant material found on earth. On the other hand Ga2O3 is a wide-band-gap semiconductor promising for high power electronic devices and UV blind photodetectors. Here we present results for the electronic structure of Fe2O3 and Ga2O3 in both monoclinic and corundum phases using different exchange correlation functionals. We show how the valence and conduction band edges change with respect to the vacuum level depending upon the choice of functional used for Fe2O3 and Ga2O3. We discuss their band alignments, and the electronic structure and stability of the Ga2O3-Fe2O3 alloys. Finally, we discuss the possibility of forming a p-n heterojunction with p-Ga2O3 and n-Ga2O3 and its characteristics.
Unusual Formation of Point Defects and Their Complexes in Ultra-wide Band Gap Beta-Ga2O3

JARED JOHNSON, Ohio State Univ - Columbus, ZHEN CHEN, Cornell University, JOEL VARLEY, Lawrence Livermore National Laboratory, CHRISTINE JACKSON, ESMAT FARZANA, AARON AREHART, HSIEN-LIEN HUANG, STEVEN RINGEL, Ohio State Univ - Columbus, CHRIS VAN DE WALLE, University of California, Santa Barbara, DAVID MULLER, Cornell University, JINWOO HWANG (Presenter), Ohio State Univ - Columbus — Beta-Ga2O3 has unique advantages including high breakdown voltage and availability as bulk substrates, which make it a viable candidate for next-generation power device applications. We present the first direct microscopic observation of the unusual formation of interstitial-divacancy complexes within beta-Ga2O3 lattice using atomic resolution scanning transmission electron microscopy. We observed that cation atoms are present in multiple interstitial sites, and each interstitial atom is paired with two adjacent vacancies. The observed structure is consistent with density functional theory calculation, which predicts them to be compensating acceptors. The number of the complexes increase as a function of Sn doping, which matches with the increase of the trap state at Ec - 2.1 eV measured using deep level optical spectroscopy, strongly suggesting that the defects correspond to that trap level. We also show that two neighboring complexes can further relax the structure in between, creating more cation vacancies. Our finding provides new crucial information on the exact structural origin of the properties of beta-Ga2O3 that has been unobtainable using other methods.

Donor and acceptor properties in Ga2O3 polymorphs

JOHN LYONS (Presenter), DARSHANA WICKRAMARATNE, Center for Computational Materials Science, United States Naval Research Laboratory, JOEL VARLEY, Lawrence Livermore National Laboratory — An ultra-wide band gap and substrate availability make Ga2O3 an attractive power electronic material. But questions still remain as to how best control its electrical conductivity through impurity doping. In this work, we evaluate the properties of acceptor and donor dopants in Ga2O3 polymorphs using first-principles calculations based on hybrid density functional theory. Hole localization and low-lying valence bands are exhibited by all Ga2O3 phases, causing deep acceptor behavior for all impurities considered. These polymorphs also share other properties, such as similar positions of the deep oxygen vacancy defect levels. In contrast, cation-site donors (such as C, Si, Ge, and Sn) are found to be shallow. These donors do exhibit defect transition levels above the Ga2O3 conduction band minimum, which may become relevant if Ga2O3 is alloyed with aluminum and the band gap increases.

12:39PM G63.00006: Optical Properties of Acceptor Impurities in Ga$_2$O$_3$  INTERÓN CHATRATIN
(Presenter), FERNANDO SABINO, Department of Materials Science & Engineering, University of Delaware, PAKPOOM REUNCHAN, Department of Physics, Kasetsart University, ANDERSON JANOTTI, Department of Materials Science & Engineering, University of Delaware — Ga$_2$O$_3$ has attracted great attention as a promising material for high power electronic applications due to a very large band gap, high breakdown voltage and ability to be doped n-type. The Ga$_2$O$_3$ Baliga’s figure of merit is only lower than that of diamond. Most importantly, large single crystals of Ga$_2$O$_3$ are available, facilitating epitaxial growth. Although p-type Ga$_2$O$_3$ have not been demonstrated as acceptor impurities tend to introduce deep acceptor levels, they can be used to make semi-insulating layers, and that can be useful in device designing. The deep levels of acceptor impurities in ultra-wide-band gap oxides are often difficult to probe experimentally. To facilitate the experimental characterization of the acceptor impurities, we employed hybrid density-functional calculations to investigate the optical transitions of acceptor impurities in monoclinic Ga$_2$O$_3$. We constructed configuration coordinate diagrams to determine the absorption and emission energies that can be compared with the optical absorption and photoluminescence measurements. The results show that all impurities exhibit deep acceptor transitions. The calculated emission energies are compared with the available experiment data.

12:51PM G63.00007: Transition levels for impurities in β-Ga$_2$O$_3$*  SUMAN BHANDARI
(Presenter), MARY ZVANUT, Univ of Alabama - Birmingham — Bulk Ga$_2$O$_3$ is of interest for both electronic and optical applications. However, the large number of different impurities often complicates understanding of the basic material properties. Confusion can be minimized by directly monitoring individual impurities using photo-induced electron paramagnetic resonance (EPR). Specifically, the present work tests the validity of several proposed defect levels in Fe-doped and Mg-doped β-Ga$_2$O$_3$ crystals by identifying each impurity, Fe$^{3+}$, Mg$^0$, and Ir$^{4+}$ with an EPR spectrum. The EPR intensity for the impurity is monitored during illumination from 1500 to 300 nm at 30 K or 130 K, and changes are associated with ionization. A photo-threshold between 2.0 and 2.3 eV where Ir$^{4+}$ increases and Fe$^{3+}$ decreases is assigned to the Ir$^{3+/4+}$ defect level, and one between 1.2 and 1.5 eV where Fe$^{3+}$ increases is assigned the Fe$^{2+/3+}$ level after consideration of the lattice relaxation. Ongoing study of the Mg-doped samples indicates that Mg$^0$ decreases between 1.6 and 1.9 eV, consistent with reported levels for Mg$^{-}/0$; however the photon energy dependence for the generation of the neutral Mg$^0$ is not yet clear. The presentation will describe procedure and analysis details, particularly for the curious case of neutral Mg.

*This work is supported by NSF-1904325
1:03PM G63.00008: Bismuth-alloyed Ga₂O₃ as a novel p-type transparent conducting oxide
XUEFEN CAI (Presenter), FERNANDO P. SABINO, ANDERSON JANOTTI, University of Delaware, SUHUAI WEI, Beijing Computational Science Res Ctr — Ga₂O₃ is a wide-band-gap semiconductor that has attracted great attention for applications in power electronics and UV-blind detectors. It is easy to make it n-type by adding Si, Ge, or Sn, yet difficult (or impossible) to make it p-type unless its electronic structure is fundamentally changed. Here we show that adding a few percent of Bi to Ga₂O₃ leads to an intermediate valence band that is sufficiently high in energy to enable p-type doping. Using first-principles calculations we study the electronic structure of Bi-alloyed Ga₂O₃ and the doping efficiency of possible acceptor impurities in this system. Specifically, we discuss the results for Mg, Zn, and Cu acceptors in (BiₓGa₁₋ₓ)₂O₃, including their most favorable incorporation sites, formation energies, and transition energy levels. We show that dilute (BiₓGa₁₋ₓ)₂O₃ alloys could be good candidates for novel p-type transparent conducting oxide that will create new opportunities in Ga₂O₃-based device design.

1:15PM G63.00009: Direct Imaging on Strain Relaxation of MBE-grown Single Phase alpha-(Al,Ga)₂O₃ on m-sapphire Substrate in Atomic Resolution Using Scanning Transmission Electron Microscopy
CELESTA CHANG (Presenter), Department of Physics, Cornell University, RIENA JINNO, DEBDEEP JENA, HUILI GRACE XING, Electrical and Computer Engineering, Cornell University, DAVID ANTHONY MULLER, Applied and Engineering Physics, Cornell University — MBE-grown corundum structured alpha-Ga₂O₃ on c-plane sapphire substrates often contains considerable amount of beta-Ga₂O₃ due to c-plane facets. Recently, a successful MBE-growth of pure alpha-(Al, Ga)₂O₃ on m-plane sapphire was reported. Here, we show the relaxation mechanism of such films by performing strain analysis with scanning transmission electron microscopy (STEM). The films are partially relaxed through dislocation cores at the interface, some of which tend to climb up into the film. High angle annular dark field (HAADF)-STEM images in plan-view shows the formation of very thin gamma-Ga₂O₃ at the interface occupying less than 1% area density. Owing to its defect spinel-type structure that requires two cation vacancies, gamma-Ga₂O₃ is believed to form naturally at the interface to accommodate the strain arising from lattice mismatch.

*This material is based on the work supported by the Cornell Center for Materials Research (CCMR) Shared Facilities, which are supported through the NSF MRSEC program (No.DMR-1719875). This work is supported by the Cornell/AFOSR ACCESS center of excellence (No. FA9550-18-1-0529).
1:27PM G63.00010: Ultrafast Optical Measurement of Defect Dynamics in \( \beta \)-Ga\(_2\)O\(_3\) using Supercontinuum Pump-Probe Spectroscopy.* ARJAN SINGH (Presenter), OKAN KOKSAL, NICHOLAS TANEN, DEBDEEP JENA, HUILI XING, FARHAN RANA, Cornell University — Ga\(_2\)O\(_3\) polymorphs have shown great promise for high power devices. \( \beta \)-Ga\(_2\)O\(_3\) has a large number of intrinsic and extrinsic defects with poorly understood properties. Non-equilibrium optical spectroscopy has proven to be a valuable tool in studying midgap defects in materials. In this work, we use optical pump-probe spectroscopy that employs a supercontinuum pulse to probe the defects and their ultrafast dynamics in a wide energy interval within the material bandgap. Our results show transient absorption of the probe pulse by midgap defects that is highly polarization selective. Our results show that hole capture times of defects scale with their separation in energy from the valence band with defects furthest away from the valence band exhibiting the slowest hole capture rates. Temperature dependence of hole capture rates indicate a thermally activated capture process involving lattice relaxation (multi-phonon process) that can be fitted with a Mott-Seitz expression. We present models to explain the nature of these defects and the ultrafast dynamics associated with the capture of photoexcited carriers by these defects.

*The research was funded by AFOSR ACCESS grant FA9550-18-1-0529.

1:39PM G63.00011: X-ray diffraction studies of GaN p-i-n structures for high power electronics* ALEXANDRA ZIMMERMAN (Presenter), JIAHENG HE, GUANJIE CHENG, DAVIDE DEL GAUDIO, JORDAN OCCENA, Materials Science and Engineering, University of Michigan, FABIAN NAAB, Michigan Ion Beam Laboratory, University of Michigan, MOHSEN NAMI, BINGJUN LI, JUNG HAN, Department of Electrical Engineering, Yale University, RACHEL GOLDMAN, Materials Science and Engineering, University of Michigan — Although silicon-based electronics are used to power light-emitting diodes and electric vehicles, their utility in high power applications is limited by a low breakdown voltage. The most promising alternative power devices consist of vertical GaN devices, which often require regrown active regions. In this work, we examine the p-i interface of a series of GaN p-i-n structures prepared with and without ex-situ ambient exposure and/or chemical etching. For the “in-situ” GaN structure, elastic recoil detection analysis (ERDA) revealed the highest interfacial \([H]\) and Rutherford backscattering shows the highest density of displaced Ga atoms, likely due to efficient incorporation of Mg\(_{Ga}\). Here, we report on x-ray diffraction studies of the crystallinity of the GaN p-i-n structures. The full width at half max (FWHM) of phi and omega scans were used to quantify the mosaicity and threading dislocation (TD) densities at the p-i interfaces. Interestingly, the lowest screw-type dislocation density and highest edge-type dislocation density are observed for the “in-situ” GaN structure. The relationship between interfacial \([H]\), displaced Ga, and screw- and edge-type dislocations will be discussed.

*We gratefully acknowledge the support of ARPA-E through AWD0000191.
Influence of interfacial defects on the electronic states at GaN p-i-n diode interfaces

GUANJIE CHENG (Presenter), JIAHENG HE, ALEXANDRA ZIMMERMAN, DAVIDE DEL GAUDIO, Department of Materials Science and Engineering, University of Michigan, FABIAN NAAB, Michigan Ion Beam Laboratory, University of Michigan, MOHSEN NAMI, BINGJUN LI, JUNG HAN, Department of Electrical Engineering, Yale University, RACHEL GOLDMAN, Department of Materials Science and Engineering, University of Michigan — Although silicon-based electronics are used for light-emitting diodes and electric vehicles, their utility in high power applications is limited by a low breakdown voltage. A promising alternative is vertical GaN devices, but these require regrown active regions. Here, we report on the influence of regrowth processing steps on interfacial defects and their electronic signatures. A comparison of GaN p-i-n structures prepared with and without ex-situ ambient exposure and/or chemical etching reveals the highest interfacial near-band edge (NBE) and donor-acceptor pair (DAP) cathodoluminescence (CL) emission from the in-situ structures. Interestingly, elastic recoil detection analysis (ERDA) and Rutherford backscattering spectroscopy reveal the lowest interfacial [H] but the highest fraction of displaced Ga atoms, suggesting efficient incorporation of Mg$_{Ga}$. On the other hand, for the ex-situ structures, minimal interfacial [H] is observed, and the highest surface NBE and DAP CL emission is apparent. Finally, for the etched/regrown structures, ERDA reveals the highest interfacial [H], and significant yellow CL emission is observed. We will discuss relationships between interfacial [H], the fraction of displaced Ga atoms, CL emission features, and diode performance.

Study of carbon-related point defects in C-doped GaN using photo-induced electron paramagnetic resonance spectroscopy

SUBASH PAUDEL (Presenter), MARY ZVANUT, Univ of Alabama - Birmingham, MICHAL BOCKOWSKI, Institute for High Pressure Physics, Police Academy of Sciences — Incorporation of carbon impurities in GaN creates semi-insulating substrates. However, the role of carbon has not been fully understood. We used photo-induced electron paramagnetic resonance (EPR) to study point defects in mm thick free-standing 10$^{17}$-$10^{19}$ cm$^{-3}$ C-doped GaN. An isotropic signal at $g \approx 1.987$ was observed at 3.5 K with an intensity which increases with carbon concentration, indicating the signal represents a C-related defect. In $[C] < 6 \times 10^{17}$ cm$^{-3}$ samples, additional signals, a neutral donor with $g_{par}=1.951$ and $g_{per}=1.950$, and an anisotropic signal with $g_{par} \approx 2.121$, were observed. The intensity of the C-related and the donor signal start to increase at 2.75 eV and decrease at 0.95 eV. The same quenching threshold for C-related and donor signals suggests that 0.95 eV represents the energy required to excite an electron to C-related defects. The ionization threshold, 0.95 eV, is consistent with the predicted value for (-/0) transition level of C$_{N}$. The decrease in donors during quenching is one order of magnitude less than the decrease in C-related defects, which suggests the change in C-related defects is not solely controlled by the donor but also by other defects such as $g_{par} \approx 2.121$ defect.

The work at UAB was supported by the National Science Foundation, NSF/DMR 1606765.
Session G64 DMP: Strong Correlation, Competing Phases, and Spin-Orbit Interactions in Complex Oxide Heterostructures

11:15AM G64.00001: Electronic reconstruction at the interface of SrIrO$_3$ and SrRuO$_3$

JOCIENNE NELSON (Presenter), NATHANIEL SCHREIBER, Cornell University, ALEXANDRU BOGDAN GEORGESCU, Center for Computational Quantum Physics, Flatiron Institute, BERIT GOODGE, CYRUS ZELEDON, LENA FITTING KOURKOUTIS, Cornell University, ANDREW MILLIS, ANTOINE GEORGES, Center for Computational Quantum Physics, Flatiron Institute — The interface between SrIrO$_3$ and SrRuO$_3$ has been the focus of much attention due to reports of emergent phenomena including the topological Hall effect and magnetic skyrmions. However, due to the presence of electron correlations, strong spin orbit interactions, and ferromagnetism, the electronic structure of the interface is challenging to predict and understand. Here we employ a combination of oxide molecular-beam epitaxy, in situ angle-resolved photoemission spectroscopy, scanning transmission electron microscopy, and density functional theory to investigate heterostructures of SrIrO$_3$/SrRuO$_3$. We perform a systematic investigation of the electronic structure of (SrIrO$_3$)$_n$(SrRuO$_3$)$_{20}$, spanning n = 1 to 10 to investigate the electronic reconstruction as a function of distance from the interface.

11:27AM G64.00002: Breaking Symmetries to Create a Robust Room-Temperature Ferrimagnetic Ferroelectric in LuFeO$_3$/CoFe$_2$O$_4$ Superlattices [Invited]

DARRELL SCHLOM (Presenter), Materials Science and Engineering, Cornell University — Materials that exhibit simultaneous order in their electric and magnetic ground states hold tremendous promise for use in next-generation, low-power memory and logic devices in which electric fields control magnetism. Such materials are, however, rare as a consequence of the competing requirements for ferroelectricity and magnetism, and until recently BiFeO$_3$ was the only material with this functionality at room temperature. Interface materials are a way to overcome these competing requirements, as was recently demonstrated for (LuFeO$_3$)$_m$/LuFe$_2$O$_4$ superlattices [J.A. Mundy et al. Nature 537 (2016) 523–527]. The rumpling imposed by the geometric ferroelectric hexagonal LuFeO$_3$ imposes a local distortion on the neighboring LuFe$_2$O$_4$—a distortion that removes the mirror symmetry that the LuFe$_2$O$_4$ layers would otherwise have. This breaking of symmetry enables the LuFe$_2$O$_4$ to become simultaneously ferrimagnetic and ferroelectric. This rumpling is distinct from strain engineering because no macroscopic strain is involved. In this presentation we extend this atomically engineered design methodology to LuFeO$_3$/CoFe$_2$O$_4$ superlattices producing a robust ground state that is simultaneously ferroelectric and ferrimagnetic at temperatures well above room temperature.

12:03PM G64.00003: Metal-insulator transition and charge transfer in complex oxide heterostructures from DFT+DMFT  
SOPHIE BECK (Presenter), CLAUDE EDERER, Materials Theory, ETH Zurich — We study the interplay between several control mechanisms on the emerging functionalities of complex oxide thin films and heterostructures composed of different early transition metal oxides, including correlated metals, Mott insulators and band insulators, using a combination of density functional theory (DFT) and dynamical mean-field theory (DMFT). We discuss several examples where factors, such as e.g. lattice mismatch-induced epitaxial strain, dimensional confinement, and multilayer engineering lead to modifications of structural as well as electronic properties, that give rise to a variety of phases not present in the corresponding bulk compounds.

In particular, we address multilayers composed of materials that share the same B-site atom, such as, for example, LaVO3/SrVO3 and LaTiO3/CaTiO3, where the electronegativity difference leads to charge transfer from the higher valent to the lower valent transition metal cation, rendering the interface to be more metallic than the bulk constituents on a length scale of few unit cells in good agreement with experimental results. We draw a conceptual comparison to other types of heterostructures and give an overview on interface effects in early transition metal oxides.

12:15PM G64.00004: Long-range magnetic reconstruction of J_\text{eff} = 1/2 pseudospins in Sr_2IrO_4 via 5d-4d interfacial interactions with Sr_2RuO_4  
MARYAM SOURI (Presenter), University of Kentucky, CHRISTOPHER DIETL, Argonne National Laboratory, EKATERINA PAERSCHKE, University of Alabama at Birmingham, GABRIEL A CALDERON ORTIZ, The Ohio State University, SUJAN SHRESTHA, University of Kentucky, JINWOO HWANG, The Ohio State University, GANG CAO, University of Colorado at Boulder, JONG WOO KIM, JUNG HO KIM, Argonne National Laboratory, AMBROSE SEO, University of Kentucky — Sr_2IrO_4 has attracted attention for its relativistic Mott insulating states originating from strong spin-orbit coupling (SOC) and electron-correlation. The strong SOC in iridates entangles the magnetic moments and orbital degrees of freedom, making the system sensitive to external stimuli.

We report the magnetic properties of Sr_2IrO_4 driven by 5d-4d interfacial interactions with Sr_2RuO_4. We have synthesized Sr_2IrO_4 thin films on Sr_2RuO_4 single crystal substrates by pulsed laser deposition. This heterostructure has never been studied before. We have observed the magnetic properties of this heterostructure are distinct from Sr_2IrO_4 thin-films under similar strain (-0.5 %) and Sr_2IrO_4 bulk crystals. Resonant inelastic x-ray scattering has revealed an anisotropic softening of magnetic excitations in the Sr_2IrO_4/Sr_2RuO_4, where the modified magnon dispersion indicates enhanced longer-range interactions between the J_\text{eff} = 1/2 pseudospins of Sr_2IrO_4. Note that this long-range magnetic reconstruction occurs throughout the entire Sr_2IrO_4. Our results imply the strong interfacial interactions between 5d iridates and 4d ruthenates. The approach of synthesizing epitaxial thin films on unconventional single crystal substrates opens a new direction of studying strongly correlated systems.
12:27PM G64.00005: Effect of Misfit Dislocation in SrIrO$_3$ heterostructures* ZHEN WANG (Presenter), DAVID A HOWE, PRAHALD SIWAKOTI, MOHAMMAD SAGHAYEZHIAN, Louisiana State University, Baton Rouge, YIMEI ZHU, Brookhaven National Laboratory, E WARD PLUMMER, JIANDI ZHANG, Louisiana State University, Baton Rouge — Iridates benefit from a large spin-orbit coupling where the Ir-O bond geometry strongly impacts both electronic and magnetic properties leading to topologically non-trivial spin textures. The coupled spin and charge combined with interface engineering provides a unique opportunity to harvest the expected magnetoelectric coupling in BaTiO$_3$ (BTO)/ SrIrO$_3$ (SIO) superlattices where induced non-centrosymmetricity is present. A clear picture of the microstructures at interface is required for understanding the intrinsic structure-property relationship. By using scanning/transmission electron microscopy, we studied the structural feature of the BTO/SIO superlattices on SrTiO$_3$ (001) substrate. Misfit dislocations are found in the superlattices to compensate the large lattice parameter and octahedra rotation mismatch between BTO and SIO. Due to the gradual relaxation of mismatch strain, the density of the misfit dislocation changes as a function of the superlattice thickness, and it almost disappears under a certain thickness. Moreover, the effect of the misfit dislocation on the magnetic property will also be discussed.

*Supported by the US Department of Energy (DOE) under Grant No. DOE DE-SC0002136.

12:39PM G64.00006: Nanophotonic Engineering of Reconfigurable Vanadium Dioxide Phases* DUSTIN SCHRECONGOST, YINXIAO Xiang, West Virginia University, HAI-TIAN ZHANG (Presenter), ROMAN ENGEL-HERBERT, Penn State Univ, CHENG CEN, West Virginia University — The metal-insulator transition in VO$_2$ has extended applications in active optoelectronics and metasurfaces. Recently we have shown that by using scanning probe lithography techniques, various insulating and metallic VO$_2$ phases can be manipulated on-demand in nanoscale. Here we study the plasmonic properties of a room-temperature monoclinic metal phase of VO$_2$ and explore planar structure designs for desired optical functionalities. As a proof of concept, reconfigurable optical polarizers and plasmonic spatial modulators have been demonstrated. These results showcase the potential of building programmable nanophotonic devices on a monolithic correlated material platform.

*Experimental work at West Virginia University was supported by the Department of Energy Grant No. DE-SC-0010399 and National Science Foundation Grant No. NSF-1454950. The work at Pennsylvania State University was supported by the National Science Foundation through Grant No. DMR-1352502 and the Penn State MRSEC program DMR-1420620.
12:51PM G64.00007: Characteristic Lengths of Interlayer Charge-Transfer in Correlated Oxide Heterostructures*  
GANESH JI OMAR (Presenter), ARIANDO ARIANDO, Natl Univ of Singapore — Electronic devices in the form of high mobility conducting channel with charge carriers can be regulated through the internal charge transfer or chemical doping. Here, we demonstrate the effect of a crystalline LaFeO$_3$ buffer layer on amorphous and crystalline LaAlO$_3$/SrTiO$_3$ heterostructures with a different characteristic length of interlayer charge transfer. The LaFeO$_3$ buffer layer acts as an energetically favored electron acceptor in both LaAlO$_3$/SrTiO$_3$ systems, resulting in modulation of interfacial carrier density and hence metal-to-insulator transition. Such different critical LaFeO$_3$ thicknesses are explained in terms of distinct characteristic lengths of the redox-reaction-mediated and polar-catastrophe-dominated charge transfer, controlled by the interfacial atomic contact and Thomas-Fermi screening effect, respectively. Our results not only shed light on the complex interlayer charge transfer across oxide heterostructures but also establish a new route to precisely tailor the charge-transfer process at a functional interface by atomically engineered buffer layers.

*This research is supported by the Agency for Science, Technology and Research (A*STAR), National University of Singapore (NUS) and the Singapore National Research Foundation (NRF).

1:03PM G64.00008: Synthesis and characterization of freestanding Sr$_2$IrO$_4$ epitaxial thin films  
SUJAN SHRESTHA (Presenter), MARYAM SOURI, MATTHEW COILE, Department of Physics and Astronomy, University of Kentucky, JIWOONG KIM, Department of Physics, Pusan National University, JOHN G CONNELL, Department of Physics and Astronomy, University of Kentucky, JONG WOO KIM, Advanced Photon Source, Argonne National Laboratory, AMBROSE SEO, Department of Physics and Astronomy, University of Kentucky — Mott insulating states in Sr$_2$IrO$_4$ have attracted substantial interest due to the coexistence of strong spin-orbit interactions and electron correlation. To understand the effect of strain on Sr$_2$IrO$_4$, we have synthesized freestanding Sr$_2$IrO$_4$ epitaxial thin films. We have deposited Sr$_2$IrO$_4$ thin films on water-soluble Sr$_3$Al$_2$O$_6$ buffer layers$^1$ using pulsed laser deposition. XRD and RSM show that the Sr$_3$Al$_2$O$_6$ buffer layer is strained compressively and Sr$_2$IrO$_4$ thin films follow the in-plane lattice constants of the buffer layer. However, the width of rocking curve of freestanding Sr$_2$IrO$_4$ thin films is about three times greater than as-grown Sr$_2$IrO$_4$ thin films. Also, the in-plane lattice constants of freestanding Sr$_2$IrO$_4$ thin films are slightly larger than Sr$_2$IrO$_4$ single crystals, presumably due to the introduction of defects during delamination. The optical spectra of freestanding Sr$_2$IrO$_4$ thin films show the blue shift of $J_{\text{eff}} = \frac{1}{2}$ interband optical transitions compared to Sr$_2$IrO$_4$ thin films grown on SrTiO$_3$. The blueshift is consistent with the result of tensile strained Sr$_2$IrO$_4$ thin films.
Freestanding Sr$_2$IrO$_4$ thin films offer an opportunity to study their properties under large strain by combining with piezoelectric or mechanical devices.

1:15PM G64.00009: Epitaxial Growth of Perovskite Vanadates*  JASON HOFFMAN (Presenter), JENNIFER E. HOFFMAN, Harvard University — Perovskite vanadates have recently attracted significant attention for their wide-range of functional properties. Below around 140 K, LaVO$_3$ undergoes a structural transition, and becomes an orbitally ordered antiferromagnetic insulator. SrVO$_3$, on the other hand, is a strongly correlated paramagnetic metal. In this work, we use oxygen-plasma assisted molecular beam epitaxy (MBE) to deposit epitaxial LaVO$_3$ and SrVO$_3$ thin films on insulating SrTiO$_3$ substrates. We use *ex-situ* x-ray diffraction and magnetotransport measurements to compare the properties of (001) and (111)-oriented samples. We also discuss the behavior of LaVO$_3$ / SrVO$_3$ heterostructures, where above-room-temperature ferromagnetism has been reported and ferroelectricity has been predicted.

*This work supported by the STC Center for Integrated Quantum Materials, NSF Grant No. DMR-1231319 and the Gordon and Betty Moore Foundation’s EPiQS Initiative through Grant No. GBMF4536.

1:27PM G64.00010: Metal-Insulator Transition in Strongly Correlated Quantum Confined SrVO$_3$ Superlattices*  ALYN JAMES (Presenter), Univ of Bristol, MARKUS AICHHORN, Institute of Theoretical and Computational Physics, Graz University of Technology, JUDE LAVEROCK, Univ of Bristol — Superlattices (such as SrVO$_3$/SrTiO$_3$) have many interesting physical phenomena influenced by orbital degeneracy, quantum confinement, interfaces and electron-electron correlations to name a few. The use of varying the number of SrVO$_3$ layers in superlattices gives a way to tune the strongly localized electron-electron correlations and the metal-insulator transition (MIT). These local correlations are beyond the predictive capabilities of standard density functional theory (DFT) calculations. Therefore, dynamical mean field theory (DMFT) needs to be used in conjunction with DFT (the DFT+DMFT method) to model these local correlations.

This talk will discuss our ongoing work on using the DFT+DMFT method to understand the fundamental electron correlation physics in previous experimental data of SrVO$_3$/SrTiO$_3$ superlattices. We investigate the effects on the correlated electron behavior of varying the thickness of SrVO$_3$ layers and propose a potential mechanism behind the MIT in these systems.

1:39PM G64.00011: Variable-temperature infrared microscopy of conducting oxide interfaces
STEFANO GARIGLIO (Presenter), WEIWEI LUO, MARGHERITA BOSELLI, JEAN-MARIE POUMIROL, IVAN ARDIZZONE, JEREMIE TEYSSIER, DIRK VAN DER MAREL, JEAN-MARC TRISCONE, ALEXEY B KUZMENKO, Univ of Geneva — Probing the local transport properties of two-dimensional electron systems confined at buried interfaces requires a non-invasive technique with a high spatial resolution. Using a scattering-type scanning near field optical microscopy, we study the conducting LaAlO$_3$/SrTiO$_3$ interface from room temperature down to 6 K [1]. We observe that the near-field optical signal is highly sensitive to the transport properties of the electron system. According to our model, such sensitivity originates from the interaction of the AFM tip with coupled plasmon–phonon modes.

1:51PM G64.00012: Direct imaging of the internal Bloch-components of polar-skyrmions and anti-hedgehogs in oxide heterostructures* YU-TSUN SHAO (Presenter), Applied and Engineering Physics, Cornell University, SUJIT DAS, Materials Science and Engineering, University of California, Berkeley, RUIJUAN XU, Applied Physics, Stanford University, SWATHI CHANDRIKA, Applied and Engineering Physics, Cornell University, HAROLD HWANG, Applied Physics, Stanford University, RAMAMOORTHY RAMESH, Materials Science and Engineering, University of California, Berkeley, DAVID ANTHONY MULLER, Applied and Engineering Physics, Cornell University — Emergent topological textures in ferroelectric heterostructures such as polar vortices and skyrmions has been the playground for exploring new phases and phenomena, exhibiting exotic functionalities including emergent chirality and local negative capacitance. These topologies can be realized in superlattices of (PbTiO$_3$)$_n$/(SrTiO$_3$)$_n$, either on a rigid substrate or fully lifted-off as 2D-like membranes. The electric analog of magnetic skyrmions, nm-scale polar-skyrmion bubbles, was recently observed yet their local dipole configurations and response to external stimuli are less explored. Results of electron diffraction-imaging show that the in-plane polarization curling direction is preserved (counter-clockwise, CCW) whether the skyrmion bubbles are elongated, merged, or broken apart under the perturbation of a focused electron probe. Furthermore, an ordered skyrmion square lattice appeared when heated to 373 K, in which a CCW curling dipole moment was surrounded by arrays of anti-hedgehogs and clockwise curling dipole moments.

2:03PM G64.00013: Self-doping in Sr2VO4/Sr2IrO4 superlattice*  YUHAO GU (Presenter), JIANGPING HU, Institute of Physics, Chinese Academy of Sciences, HANGHUI CHEN, Department of Physics, New York University Shanghai — Searching for high transition temperature superconductivity in non-cuprate materials has always been one of the focus topics in condensed matter physics. Theoretically, Sr2IrO4 has been proposed as a promising candidate to induce high Tc superconductivity because of the similarity of its electronic structure to that of cuprates [1]. Experimentally, surface-electron doped Sr2IrO4 exhibits spectroscopic signatures that are consistent with a superconducting gap but a zero-resistance state is yet to be found [2,3]. Here we artificially design a Sr2VO4/Sr2IrO4 superlattice, composed of VO2 layer and IrO2 layer alternating along the c-axis. Our ab initio calculations show that only V-dxy band and Ir-J=1/2 band cross the fermi level, forming a coupled two-dimensional Hubbard model with self-doping. The superlattice can be used as an effective way to electron dope iridates without introducing chemical disorder.

Session G65 DMP: Defects and Dopants in Low Dimensional Materials
Mile High Ballroom 4F - Jinkyoung Yoo - Tag(s): Focus

11:15AM G65.00001: Covalent Quantum Defects of Carbon Nanotubes: A New Material for Quantum Information Science*  HAN HTOON (Presenter), Center for Integrated Nanotechnologies, Materials Physics and Applications Division, LOS ALAMOS NATL LAB — sp³ defects of single wall carbon nanotubes (SWCNTs), often referred to “organic color centers”,¹ are rapidly emerging as a new material system for chemistry, physics, materials science, engineering and quantum technologies. These defects are created via covalent bonding of organic functional groups to the sp² lattice of SWCNTs and display quantum mechanical properties in a way similar to color centers of solid state systems. In this talk, I will provide a brief over view on our recent accomplishments in understanding and controlling quantum optical properties of this new material system. Specifically, I will cover (1) unique molecularly tunable electronic structures of these covalent quantum defects², (2) demonstration of room temperature single photon emission at 1.55 µm telecommunication wavelength with 0.99 single photon purity,³ ⁴ and (3) single defect magneto PL experiment revealing hidden spin sensitive electronic fine structure states.

11:51AM G65.00002: Carrier recombination mechanisms at quantum point defects in wide band gap two-dimensional materials*  
TYLER SMART (Presenter), Physics, University of California, Santa Cruz, FENG WU, JUNQING XU, YUAN PING, Chemistry and Biochemistry, University of California, Santa Cruz — The identification and design of defects in two-dimensional (2D) materials as promising defect based qubits and single photon emitters requires a deep understanding of the underlying carrier recombination mechanisms. Yet, the dominant mechanism of carrier recombination at defects in 2D materials has not been well understood. In order to address these concerns, we developed first-principles methods to calculate the radiative and nonradiative recombination rates at defects in 2D materials, using h-BN as a prototypical example. We reveal the carrier recombination mechanism at defects in 2D materials being mostly dominated by defect-defect state recombination. In particular, we disentangle the nonradiative recombination mechanism into key physical quantities: the zero-phonon line and Huang-Rhys factor. At the end, we identified that strain can effectively tune the electron-phonon coupling at defect centers and drastically change the nonradiative recombination rates. This work serves as a general platform for understanding carrier recombination at defects in 2D materials, while providing pathways for engineering of quantum efficiency.

*This work is supported by NSF DMR-1760260 and DMR-1747426.

12:03PM G65.00003: Curvature-driven atomic localization and dipole alignment of quantum emitters in h-BN  
DONGGYU YIM (Presenter), MIHYANG YU, GICHANG NOH, JIEUN LEE, HOSUNG SEO, The Energy System, Ajou Univ — Hexagonal boron nitride (h-BN) has recently emerged as a promising materials platform for developing various solid-state quantum technologies. In particular, a number of color centers in h-BN have been found to be stable and bright single-photon-emitters (SPEs) operating at room temperature, which are crucial elements for quantum optical applications. In this talk, we combine first-principles theory and experiment to investigate the intimate relation between curvature in h-BN and atomic localization of SPEs. We use density functional theory to calculate the energetically stable configuration of various defect models of the SPEs in a buckled h-BN plane with different curvatures. We show that the vacancy-derived point defects in h-BN prefer to form in the highest-curvature area of the buckle and we find that the high curvature induces a dimer reconstruction for the atoms surrounding vacancy. Our result provides not only a microscopic understanding on the recent experimental observations of the SPEs being located in h-BN buckles but also strongly suggests that the atomic origin of the SPEs may be vacancy-derived. We also discuss several key features of the SPEs formed on h-BN buckle such as dipole orientation, which would be helpful to design future experiments of the SPEs in h-BN.
12:15PM G65.00004: Excitons and Radiative Lifetimes at Point Defects in Hexagonal Boron Nitride from First Principles* SHIYUAN GAO (Presenter), HSIAO-YI CHEN, MARCO BERNARDI, Caltech — Point defects in hexagonal boron nitride (hBN) have been recently investigated as promising single-photon emitters. Previous theoretical work has proposed candidate atomic structures for these localized emitters using density-functional theory (DFT) calculations, which focused on the defect formation energy, symmetry, and single-particle electronic transitions. Here, we use DFT plus the GW-Bethe-Salpeter equation method to compute the ground and excited states of a set of candidate hBN defect structures. Our calculations can predict the band gap, excitons and radiative lifetimes of the various defects, while including anisotropic dielectric screening and spin-orbit interaction effects. We show that the radiative lifetime can differ by orders of magnitude among different candidate structures, and it can be used as an effective physical quantity to rule out candidate defects. We analyze our results for the most promising structure, which exhibits energy and radiative lifetime in very good agreement with experiment. Through a statistical analysis, we comment on the likelihood that our calculations can successfully identify the structure behind the single-photon emitters observed experimentally.

*This work was supported by the Department of Energy under Grant No. DE-SC0019166.

12:27PM G65.00005: Ab initio theory of negatively charged boron vacancy qubit in hBN* VIKTOR IVÁDY (Presenter), GERGELY BARCZA, GERGŐ THIERING, Wigner Research Center for Physics, SONG LI, City University of Hong Kong, HANEN HAMDI, ÖRS LEGEZA, Wigner Research Center for Physics, JYH PIN CHOU, City University of Hong Kong, ADAM GALI, Wigner Research Center for Physics — Highly correlated orbitals coupled with phonons in two-dimension are identified for paramagnetic and optically active boron vacancy in hexagonal boron nitride by first principles methods which are responsible for recently observed optically detected magnetic resonance signal. We report on ab initio analysis of the correlated electronic structure of this center by density matrix renormalization group and Kohn-Sham density functional theory methods. By establishing the nature of the bright and dark states as well as the position of the energy levels, we provide a complete description of the magneto-optical properties and corresponding radiative and non-radiative routes which are responsible for the optical spin polarization and spin dependent luminescence of the defect. Our findings pave the way toward advancing the identification and characterization of room temperature quantum bits in two-dimensional solids.

Boron Dangling Bonds as Single Photon Emitters in Hexagonal Boron Nitride

MARK TURIANSKY (Presenter), University of California, Santa Barbara, AUDRIUS ALKAUSKAS, Center for Physical Sciences and Technology (FTMC), LEE BASSETT, University of Pennsylvania, CHRIS VAN DE WALLE, University of California, Santa Barbara — Defects in semiconductors are an attractive candidate to realize quantum information applications such as quantum computing and cryptography, as well as nanoscale sensing. Hexagonal boron nitride (h-BN) is a desirable host for these quantum defects due to its two-dimensional crystal structure, excellent stability, and wide band gap. Single-photon emission has been observed in h-BN from point defects in the lattice, but microscopic identification of the underlying defect has proved elusive. In this work, we employ hybrid density functional theory to demonstrate that the properties of boron dangling bonds are consistent with the experimental reports. Specifically, doubly occupied boron dangling bonds give rise to optical emission at 2.06 eV with a Huang-Rhys factor of 2.3. The emission is linearly polarized, with indirect excitation into the conduction band explaining the lack of dipole alignment seen in experiment. The boron dangling bond possesses a metastable triplet state, which can be used to realize spin-sensing applications.

This work is supported by NSF.

Influence of the environment on the coherence properties of spin-defects in low-dimensional solids and nanostructures: a computational study

MYKYTA ONIZHUK (Presenter), University of Chicago, MENG YE, Department of Physics, Tsinghua University, GIULIA GALLI, University of Chicago — Several recent studies have shown that in three-dimensional materials (e.g. diamond and SiC), at low temperature and in the presence of a large magnetic field, the central spin decoherence is mainly due to the fluctuating magnetic field induced by nuclear spin flip-flop transitions. Hence the interaction between electronic defects with the nuclear spin bath of the crystal is the dominant one in determining spin-defect decoherence times. However, in the case of two-dimensional (2D) and nanostructured semiconductors, the interaction with the environment, for example a supporting substrate, is expected to significantly affect spin-coherence times. We present a computational study aimed at understanding environmental effects on coherent lifetimes of spin-defects. We evaluated coherence functions using the Cluster Correlation Expansion method, and we computed the Hahn-echo $T_2$ time – an important metric for qubit performance – for spin defects in 2D transition metal di-chalcogenides [1] interacting with various substrates, and for nanodiamonds with different surface terminations.

1:03PM G65.00008: Carbon dimers as the source of 4.1 eV luminescence in hexagonal boron nitride*

MAZENA MACKOIT-SINKEVICIENE, Center for Physical Sciences and Technology (FTMC), Vilnius, Lithuania, MAREK MACIASZEK, Faculty of Physics, Warsaw University of Technology, Poland, CHRIS VAN DE WALLE (Presenter), University of California, Santa Barbara, AUDRIUS ALKAUSKAS, Center for Physical Sciences and Technology (FTMC), Vilnius, Lithuania — Hexagonal boron nitride (h-BN) is an exciting material for electronics and optoelectronics, as well as for quantum information applications. h-BN samples typically display bright luminescence with a zero-phonon line (ZPL) at 4.1 eV, and single-photon emission associated with this line has been observed. The source of the luminescence has been intensely debated, though there seems to be broad agreement that carbon is involved. We propose that the carbon dimer, C\textsubscript{B}–C\textsubscript{N}, gives rise to this ubiquitous narrow luminescence band. Such carbon dimers have actually been observed in transmission electron microscopy. Our first-principles calculations, based on hybrid density functional theory, show that the neutral state of the dimer is stable over a wide range of electron chemical potentials. The calculated ZPL energy, Huang-Rhys factor, and radiative lifetime are all close to the experimental values. The optical transition occurs between two localized π-type defect states, with the lower-lying state localized on C\textsubscript{N}, while the higher-lying state is localized on C\textsubscript{B}. We find the transition to be dipole allowed with polarization in the h-BN plane.

1:15PM G65.00009: Gate-defined quantum dots in monolayer and bilayer WSe\textsubscript{2}: Part I, Fabrication*

JEB STACY (Presenter), SHIVA DAVARI DOLATABADI, ALEJANDRO MERCADO TEJERINA, JEREMY TULL, RABINDRA BASNET, KRISHNA PANDEY, MD NABI, Physics, Univ of Arkansas-Fayetteville, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, JIN HU, HUGH CHURCHILL, Physics, Univ of Arkansas-Fayetteville — Gate-defined quantum dots in monolayer and bilayer WSe\textsubscript{2} are a platform for novel quantum transport and quantum optoelectronic investigations of WSe\textsubscript{2}, as well as for potential applications in coherent valleytronics. In this presentation, we discuss design considerations and implementations for the fabrication of ~100 nm diameter gate-defined, p-type quantum dots in monolayer and bilayer WSe\textsubscript{2}. The devices were controlled using a combination of bottom confining gates and a top accumulation gate, with hBN used for gate insulation and encapsulation of the WSe\textsubscript{2}. Top hBN and WSe\textsubscript{2} were transferred onto Pt for reliable p-type bottom contact.

*We acknowledge support from AFOSR award FA-9550-16-1-0203
1:27PM G65.00010: Gate-defined quantum dots in monolayer and bilayer WSe$_2$: Part II, Measurement*  
SHIVA DAVARI DOLATABADI (Presenter), JEB STACY, ALEJANDRO MERCADO TEJERINA, JEREMY TULL, RABINDRA BASNET, KRISHNA PANDEY, MD NABI, Physics, Univ of Arkansas-Fayetteville, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, JIN HU, HUGH CHURCHILL, Physics, Univ of Arkansas-Fayetteville — Gate-defined quantum dots in monolayer and bilayer WSe$_2$ are a platform for novel quantum transport and quantum optoelectronic investigations of WSe$_2$, as well as for potential applications in coherent valleytronics. In this presentation, we discuss low-temperature electronic transport measurements of p-type gate-defined quantum dots in monolayer and bilayer WSe$_2$. These devices are operated with gates above and below the WSe$_2$ layer so that carriers are accumulated in the WSe$_2$, then selectively depleted to define the dot. We report observations of Coulomb blockade as well as excited state spectroscopy of confined holes in WSe$_2$ dots. 

*We acknowledge support from AFOSR award FA-9550-16-1-0203.

1:39PM G65.00011: A carbon dimer defect as a spin qubit candidate in hexagonal boron nitride: an ab-initio study  
JOOYONG BHANG (Presenter), DONGGYU YIM, Department of Energy Systems Research, Ajou University, Suwon, Gyeonggi 16499, Korea, HE MA, GIULIA GALLI, Pritzker School of Molecular Engineering, University of Chicago, Chicago, IL 60637, USA, HOSUNG SEO, Department of Energy Systems Research, Ajou University, Suwon, Gyeonggi 16499, Korea — Hexagonal boron nitride has been recently found to host a variety of quantum defects that are potentially useful for advancing solid-state quantum technologies. However, optically addressable spin quantum bits (qubits), such as the diamond NV center, have not yet been reported in h-BN. In this talk, we propose a carbon dimer(C$_2$) defect as a promising candidate of optically active spin qubit in h-BN. We use first-principles density functional theory to investigate its structural and electronic properties. We show that the C$_2$ defect features a non-zero spin ground state (S=1), arising from defect-induced deep levels in the band gap of the host material, and localized unpaired electrons. We calculate the defect formation energy of the C$_2$ defect and other C-related defects in h-BN and we show that the C$_2$ defect is energetically stable. To assist potential future experiments, we report the zero-phonon line, the zero-field splitting tensor, and the hyperfine tensor of the C$_2$ defect at various DFT levels of theory, including the HSE hybrid functional. Our study aimed at searching coherent spin qubits in h-BN can be potentially applied to a wide variety of other two-dimensional van der Waals materials systems.
1:51PM G65.00012: Ab initio design and control of quantum emitters in low-dimensional materials

CHITRALEEMA CHAKRABORTY (Presenter), CHRISTOPHER CICCARINO, PRINEHA NARANG, Harvard University — The formation of atomic defects is unavoidable in 2D materials with currently available growth techniques\(^1\). Nevertheless, a myriad of functionalities in modern optoelectronic and nanophotonic devices leverage quantum defects including the recent demonstration of single photon emitters in 2D materials\(^2\). In parallel, advances in scanning probe techniques provide opportunities to directly create, manipulate and characterize defects down to the atomic scale in 2D materials\(^3\). We predict optically active quantum defects in 2D transition metal dichalcogenides from first-principles. We will discuss the excited state defect configuration(s) and the corresponding electron-phonon interactions\(^4\) to quantify the optical efficiency of emitters via the Huang-Rhys factor. Our work presents a pathway for maximizing the optical efficiency of designer quantum emitters in low-dimensional systems and provides a deterministic choice for defect creation at the atomic scale\(^3\).

*This work was supported by DOE ‘Photonics at Thermodynamic Limits’ Energy Frontier Research Center under grant DE-SC0019140.

2:03PM G65.00013: Mie Resonant Dielectric Metastructure based Quantum Optical Circuits Integrated with Single Photon Source: A new paradigm for Quantum Information Processing

SWARNABHA CHATTARAJ (Presenter), JIEFEI ZHANG, Univ of Southern California, SIYUAN LU, IBM Thomas J. Watson Research Center, ANUPAM MADHUKAR, Univ of Southern California — Realization of scalable optical quantum information processing systems requires optical circuits built around on-chip single photon sources (SPS) in spatially regular arrays\(^1\) to provide the needed light manipulating functions of enhancement of SPS emission rate, control on emission directionality, guiding, splitting and recombining to enable on-chip controlled photon interference and entanglement. To this end we have introduced use of light manipulating units (LMU) based on metastructures of subwavelength dielectric building blocks in which a collective Mie mode provides all the above noted functions while eliminating mode mismatch between the components of the network, including the SPS\(^2\). In this talk we present FEM based simulation and design of such SPS-LMUs that result in two types of entanglement over large on-chip distances: (1) path-entanglement via interference of photons from distinct SPSs, and (2) emergence of coherence and entanglement via direct photon-mediated long-range coupling resulting in super-radiance with ~2-fold decay rate enhancement of the coupled SPSs\(^3\).

11:15AM G66.00001: Spin-triplet superconducting state in the nearly ferromagnetic compound UTe2 [Invited]  SHENG RAN (Presenter), University of Maryland, College Park — Our recent discovery of the novel spin-triplet superconductivity in UTe2 [1] has inspired a lot of interests in the community. Superconducting state of UTe2 closely resembles that of ferromagnetic superconductors, but the normal state is paramagnetic with no indication of magnetic ordering. Unusual properties of $H_c^2$, NMR Knight shift, and specific heat strongly indicate that the superconductivity in UTe2 is carried by spin-triplet pairs. Even more striking, superconductivity reenters in the magnetic field of 45 tesla and persists up to 65 tesla, reflect a new kind of exotic superconductivity rooted in magnetic fluctuations and quantum dimensionality [2]. Application of pressure reveals a two-fold enhancement of this unusual superconductivity, which is closely related to the suppression of Kondo coherence [3]. In this talk, I will review our recent results on UTe2.

11:51AM G66.00002: Field- and pressure-induced phenomena in novel spin-triplet superconductor UTe2* [Invited]  DAI AOKI (Presenter), Tohoku Univ — We present our recent results on the novel spin-triplet superconductor UTe2, which is at the verge of the ferromagnetic order. The huge upper critical field exceeding the Pauli limit indicates the spin-triplet state. For the field along b-axis, the field reentrant superconductivity is observed up to $H_m \sim 35$T, where the first order metamagnetic transition occurs. The field reentrant superconductivity in UTe2 is similar to that observed in ferromagnetic superconductors, namely URhGe and UCoGe. Applying the pressure in UTe2, the superconducting transition temperature splits and the mulitple superconducting phase is detected in the AC calorimetry measurements. We overview the results on UTe2 comparing with ferromagnetic superconductors, and show our perspective. This work was done in collaboration with G. Knebel, A. Pourret, J.P. Brison, D. Braithwaite, Q. Niu, M. Valiska, J. Flouquet, A. Nakamura, F. Honda, Y. Homma, D.XLi, Y. Shimizu, Y. J. Sato, A. Miyake, S. Imajo, S. Kohama, M. Tokunaga, H. Harima, W. Knafo, I. Sheikin, C. Paulsen, Y. Tokunaga, S. TRISTIN METZ (Presenter), SEOKJIN BAE, Center for Quantum Materials, University of Maryland, SHENG RAN, I-LIN LIU, NIST Center for Neutron Research, YUN SUK EO, WESLEY T FUHRMAN, Center for Quantum Materials, University of Maryland, DANIEL AGTERBERG, Physics, University of Wisconsin, Milwaukee, STEVEN ANLAGE, Center for Quantum Materials, University of Maryland, NICHOLAS BUTCH, NIST Center for Neutron Research, JOHNPIERRE PAGLIONE, Center for Quantum Materials, University of Maryland — Low-temperature electrical and thermal transport, magnetic penetration depth, and heat capacity measurements were performed on single crystals of the actinide superconductor UTe$_2$ ($T_c$=1.6K) to determine the structure of the superconducting energy gap. Heat transport measurements performed with currents directed along both crystallographic a- and b-axes reveal a vanishingly small residual fermionic component of the thermal conductivity. The magnetic field dependence of the residual term follows a quasi-linear increase consistent with the presence of nodal quasiparticles, rising rapidly toward the a-axis upper critical field where the Wiedemann-Franz (WF) law is recovered. Together with a quadratic temperature dependence of the magnetic penetration depth up to $T/T_c$= 0.3, these measurements provide evidence for an unconventional spin-triplet superconducting order parameter with point nodes positioned along the crystallographic a-axis. Millikelvin specific heat measurements reveal an upturn below 300 mK that is well described by a divergent quantum-critical contribution to the density of states (DOS). Modeling this contribution with a $T^{-1/3}$ power law allows restoration of the full entropy balance in the superconducting state and reveals a perfect $T^3$ power law for the electronic DOS below $T_c$ which is consistent with the point nodal gap structure determined by thermal conductivity and penetration depth measurements.
1:03PM G66.00004: Electronic band structure of triplet superconductor UTe₂ from angle resolved photoemission spectroscopy* [Invited] L. ANDREW WRAY (Presenter), New York Univ NYU, LIN MIAO, Southeast University, SHOUZHENG LIU, YISHUAI XU, ERICA KOTTA, New York Univ NYU, SHENG RAN, NIST Center for Neutron Research, JOHNPIERRE PAGLIONE, Univ of Maryland-Colege Park, JONATHAN DENLINGER, Lawrence Berkeley National Laboratory, NICHOLAS BUTCH, NIST Center for Neutron Research — The compound UTe₂ has recently been shown to realize spin triplet superconductivity from a non-magnetic normal state. This has sparked intense research activity, including theoretical analyses that suggest the superconducting order parameter to be topologically nontrivial. However, the underlying electronic band structure is a critical factor for these analyses, and remains poorly understood. I will present high resolution angle resolved photoemission (ARPES) measurements covering multiple planes in the 3D Brillouin zone of UTe₂, revealing distinct Fermi pockets from two light electron bands and one heavy band. Electronic symmetries and many-body ordering instabilities will be discussed in comparison with numerical simulations.

1:39PM G66.00005: Coexistence of ferromagnetic fluctuations and superconductivity in the actinide superconductor UTe₂* [Invited] JEFF SONIER (Presenter), Simon Fraser Univ — We report low-temperature muon spin relaxation/rotation (μSR) measurements on single crystals of the actinide superconductor UTe₂. Below 5 K, we observe a continuous slowing down of magnetic fluctuations that persists into the superconducting state, but find no evidence of long-range or local magnetic order down to millikelvin temperatures. The temperature dependence of the dynamic relaxation rate is consistent with spin fluctuations for a three-dimensional weak itinerant ferromagnetic metal, and suggests UTe₂ is close to a ferromagnetic quantum critical point. Our μSR results also indicate that the superconductivity coexists with the magnetic fluctuations and similar to other actinide-based superconductors, UTe₂ has a very low superfluid density.

Session G67 DCMP: Quantum Valley Hall Edge Channels: Highways for Electrons, Photons, and Surface Plasmons Four Seasons 2-3 - Long Ju, Massachusetts
11:15AM G67.00001: Topological valleytronics using kink states in bilayer graphene: a valley valve and beam splitter [Invited] JING LI (Presenter), Los Alamos National Laboratory — Two-dimensional honeycomb lattices possess a valley degree of freedom, the control of which offers opportunities to realize topologically protected edge modes to transport electrons without dissipation, and potentially contribute to new paradigms of electronics, namely valleytronics. In this talk, I will describe how we realize valley-momentum locked topological 1D channels, i.e. quantum valley Hall kink states, at internal line boundaries of two artificial domains of Bernal stacked bilayer graphene with opposite band gaps via asymmetrical gating [1]. These kink states possess mean free path of a few µm at B=0, and their helicity (±1) can be conveniently controlled by changing the gating polarity. In an all electrically defined “cross” device with 4 channels, I will demonstrate reconfigurable ballisitic waveguides of the kink states, and valleytronic operations such as valley valve and electron beam splitter that exploit topological protection [2]. Kink states can ballistically transmit through two channels with aligned helicity (on state), while get blocked between channels with opposite helicity (off state). The on/off ratio reaches 800% at B=0, and it doesn't require valley-polarized current to operate, instead relying on the control of topology. In a B-field, Fermi energy becomes a knob to continuously tune the current splitting ratio of kink states in two propagation directions, resembling the function of a quantum point contact for quantum Hall edge states. The versatile control and potential scalability of the kink states open the door to many exciting possibilities in low dimensional topological applications.

11:51AM G67.00002: Polaritons in Moire Superlattices of Graphene and Boron Nitride [Invited] DMITRI BASOV (Presenter), Physics, Columbia University — Electronic properties of graphene can be drastically altered when it is laid upon another graphene layer, resulting in a moiré superlattice. The relative twist angle between the two layers is a key tuning parameter of the interlayer coupling in thus-obtained twisted bilayer graphene (TBG). We studied the propagation of plasmon polaritons in TBG by infrared nano-imaging. The atomic reconstruction occurring at small twist angles transforms the TBG into a network of conducting channels that act as efficient reflectors of plasmon polaritons. The analysis of plasmonic images allows one to infer the conductivity of the domain walls in moire superlattices. TBG at small twist angles effectively acts a natural plasmon photonic crystal for propagating nano-light. We observed similar nano-optical effects in other twisted van der Waals crystals including hexagonal boron nitride. In hBN, domain walls modify the response of phonon polaritons.
12:27PM G67.00003: Topological photonics: slow light and solitons* [Invited] MIKAEL RECHTSMAN (Presenter), SEBABRATA MUKHERJEE, JONATHAN GUGLIELMON, Pennsylvania State University — In this talk we will describe the realization of chiral edge states for photons in a photonic Floquet topological insulator, employing optical waveguide arrays. We will describe how such topological states can be used to simultaneously overcome two shortcomings of slow-light systems, namely disorder-induced scattering (and Anderson localization) as well as low bandwidth. We will show how optical nonlinearity can be used to realize Gross-Pitaevskii-type interactions, and a resulting soliton that spectrally resides in a topological band gap.

1:03PM G67.00004: The electron thickness of graphene [Invited] KLAUS ENSSLIN (Presenter), ETH Zurich — The van-der-Waals stacking technique enables the fabrication of heterostructures, where two conducting layers are atomically close. In this case, the finite layer thickness matters for the interlayer electrostatic coupling. Here we investigate the electrostatic coupling of two graphene layers, twisted by 22 degrees such that the layers are decoupled by the huge momentum mismatch between the K and K' points of the two layers. We observe a splitting of the zero-density lines of the two layers with increasing interlayer energy difference. This splitting is given by the ratio of single-layer quantum capacitance over interlayer capacitance C and is therefore suited to extract C. We explain the large observed value of C by considering the finite dielectric thickness d of each graphene layer and determine d=2.6 Angstrom. In a second experiment we map out the entire density range with a Fabry-Pérot resonator. We can precisely measure the Fermi-wavelength in each layer, showing that the layers are decoupled. We find that the Fermi wavelength exceeds 600nm at the lowest densities and can differ by an order of magnitude between the upper and lower layer. These findings are reproduced using tight-binding calculations.

1:39PM G67.00005: Atomic and electronic reconstruction at van der Waals interface in twisted 2-D materials [Invited] HYOBIN YOO (Presenter), Sogang University — Controlling the interlayer twist angle in two-dimensional (2-D) van der Waals (vdW) heterostructures offers an experimental route to create moire superlattices. One can realize exotic electronic states by adjusting the width of the electronic bands with a tunable moire length scale. However, in the small twist angle regime, vdW interlayer interaction can cause significant structural reconfiguration at the interface, creating the arrays of domain structures. In this talk, we will discuss the atomic reconstruction at twisted vdW interfaces and its effect on electronic structure and electrical transport behavior. Moreover, one can tune the domain topology at the reconstructed interface using 2-D vdW crystals that has lower symmetry. We will discuss the connection between crystal symmetry and tunable domain topology.
Session G68 DQI: Superconducting Qubit Quantum Simulation and Algorithms

11:15AM G68.00001: Quantum Supremacy: Benchmarking the Sycamore Processor [Invited]
KEVIN SATZINGER (Presenter), Google Inc - Santa Barbara — The promise of quantum computers is that certain computational tasks might be executed exponentially faster on a quantum processor than on a classical processor. A fundamental challenge is to build a high-fidelity processor capable of running quantum algorithms in an exponentially large computational space. Here we report the use of a processor with 53 programmable superconducting qubits. In our Sycamore processor, each qubit interacts with four neighbors in a rectangular lattice using tunable couplers. A key systems engineering advance of this device is achieving high-fidelity single- and two-qubit operations, not just in isolation but also while performing a realistic computation with simultaneous gate operations across the entire processor. We benchmark the Sycamore processor using cross-entropy benchmarking, a scalable method to evaluate system performance. Our largest system benchmarks feature circuits that are intractable for classical hardware, culminating in the demonstration of quantum supremacy. Furthermore, the fidelities from full-system benchmarks agree with what we predict from individual gate and measurement fidelities, verifying the digital error model and presenting a path forward to quantum error correction.

Nature 574, 505-510 (2019)

11:51AM G68.00002: Quantum supremacy using the Sycamore processor
CHARLES NEILL (Presenter), Google Inc - Santa Barbara — The promise of quantum computers is that certain computational tasks might be executed exponentially faster on a quantum processor than on a classical processor. A fundamental challenge is to build a high-fidelity processor capable of running quantum algorithms in an exponentially large computational space. Recently, our team has demonstrated a dramatic speedup relative to all known classical algorithms providing an experimental realization of quantum supremacy on a computational task. In this talk, I will focus on the hardware details of the Sycamore processor and how this device enabled supremacy-quality two-qubit gates.
Electromagnetic fields possess zero point fluctuations (ZPF) which lead to observable effects such as the Lamb shift and the Casimir effect. In the traditional quantum optics domain, these corrections remain perturbative due to the smallness of the fine structure constant. To provide a direct observation of non-perturbative effects driven by ZPF in an open quantum system we wire a highly non-linear Josephson junction to a high impedance transmission line, allowing large phase fluctuations across the junction. Consequently, the resonance of the former acquires a relative frequency shift that is orders of magnitude larger than for natural atoms. Detailed modelling confirms that this renormalization is non-linear and quantum. Remarkably, the junction transfers its non-linearity to about 30 environmental modes, a striking back-action effect that transcends the standard Caldeira-Leggett paradigm. This work opens many exciting prospects for longstanding quests such as the tailoring of many-body Hamiltonians in the strongly non-linear regime, the observation of Bloch oscillations, or the development of high-impedance qubits.

Analog quantum simulation of a Kondo impurity with superconducting circuits  

NICHOLAS GRABON (Presenter), ROMAN KUZMIN, NITISH JITENDRAKUMAR MEHTA, University of Maryland, College Park, MOSHE GOLDSTEIN, Tel Aviv University, VLADIMIR MANUCHARYAN, University of Maryland, College Park —

A particular quantum simulator can be used to access the many body properties of the Kondo problem [1]. We created the first experimental realization of this quantum simulator. The simulator is comprised of a high impedance Josephson junction waveguide connected to a fluxonium qubit at its end. The fluxonium hosts a fluxon mode that can be far detuned from any of the other transitions. It can thus be considered as a two level system that then acts as the spin in the simulated Kondo model. This spin couples to a continuum of modes in the waveguide, which acts as the bath, thus completing the model. We study the spectra of inelastic and elastic scattering of the waveguide photons which are expected to reveal the many body correlation functions of the Kondo model.

12:39PM G68.00006: Simulating a Dirac particle with coupled transmon circuits* ELISHA SVETITSKY (Presenter), NADAV Y KATZ, Hebrew University of Jerusalem — The core concept of quantum simulation is the mapping of an inaccessible quantum system onto a controllable one by identifying analogous dynamics. We map the Dirac equation of relativistic quantum mechanics in 3+1 dimensions onto a multi-level superconducting Josephson circuit. Resonant drives determine the particle mass and momentum and the quantum state represents the internal spinor dynamics, which are cast in the language of multi-level quantum optics. The degeneracy of the Dirac spectrum corresponds to a degeneracy of bright/dark states within the system and particle spin and helicity are employed to interpret the multi-level dynamics. We simulate the Schwinger mechanism of electron-positron pair production by introducing an analogous electric field as a doubly degenerate Landau-Zener problem. All proposed measurements can be performed well within typical decoherence times. This work opens a new avenue for experimental study of the Dirac equation and provides a tool for control of complex dynamics in multi-level systems.

12:51PM G68.00007: Quantum Simulation of Hyperbolic Space with Circuit Quantum Electrodynamics: From Graphs to Geometry* IGOR BOETTCHER (Presenter), PRZEMYSLAW BIENIAS, RON BELYANSKY, ALICIA KOLLAR, Joint Quantum Institute, University of Maryland, College Park, MD 20742, USA, ALEXEY V GORSHKOV, Joint Center for Quantum Information and Computer Science, NIST/University of Maryland, College Park, MD 20742, USA — We give a quantum field theoretic perspective on recent breakthrough experiments in circuit quantum electrodynamics, where hyperbolic lattices are realized with superconducting resonators and photons are tricked into believing that space is hyperbolic. We show how these finite lattice geometries can be mapped onto quantum field theories in continuous negatively curved space. We use this as a computational tool to quantitatively reproduce ground state energy, spectral gap, and correlation functions of the noninteracting lattice system by means of analytic formulas on the Poincare disk, and show how conformal symmetry emerges for large lattices. I will discuss how interaction effects can be induced by coupling qubits to the hyperbolic lattice. This sets the stage for studying interactions and disorder on hyperbolic graphs, and to resolve fundamental open problems at the interface of interacting many-body systems, quantum field theory in curved space, and quantum gravity using tabletop experiments.

Demonstration of programmable quantum simulations of lattice models using a superconducting parametric cavity

JAMAL BUSNAINA (Presenter), JIMMY SHI-HUN HUNG, M.V. MOGHADDAM, CHUNG WAI SANDBO CHANG, A.M. VADIRAJ, Institute for Quantum Computing and Department of Electrical Engineering, University of Waterloo, HADISEH ALAEIAN, Physikalisches Institut, Universität Stuttgart, ENRIQUE RICO, Department of Physical Chemistry, University of the Basque Country, C.M. WILSON, Institute for Quantum Computing and Department of Electrical Engineering, University of Waterloo — There has been a growing interest in realizing quantum simulators for important physical systems where perturbative methods are ineffective. The scalability and flexibility of circuit quantum electrodynamics (cQED) make it a promising platform for implementing various types of simulators, including lattice models of strongly-coupled field theories. With this in mind, we use a multimode superconducting parametric cavity to create programmable lattices of bosonic modes by parametrically pumping at mode-difference frequencies. The choice of pump frequencies allows changing the graph of the lattice in situ. Further, the resulting hopping terms induced between the modes can be made complex by controlling the relative phases of the parametric drives. This enables us to study a wide variety of interesting lattice models. For instance, controlling the total loop phase in closed plaquettes allows us to simulate the motion of particles in a static gauge field, including producing nonreciprocal transport. The system can also realize models with topological features such as the bosonic Creutz ladder. In this talk, we present experimental results on a variety of different small lattice models.

Quantum simulation of a spin chain with superconducting circuits

QUENTIN FICHEUX (Presenter), AARON SOMOROFF, NITISH JITENDRAKUMAR MEHTA, ROMAN KUZMIN, University of Maryland, College Park, IVAR MARTIN, Argonne National Laboratory, MAXIM G VAVILOV, University of Wisconsin-Madison, VLADIMIR MANUCHARYAN, University of Maryland, College Park — An Ising chain is one of the simplest many-body systems to exhibit a quantum phase transition. In the presence of a transverse field and disorder, this model produces a rich variety of non integrable ground states giving rise to exotic phase transitions including many body localization and Anderson localization.

Initial experimental efforts to simulate this model have focused on cold atoms [1] and trapped ion systems [2,3] with limited coupling strength imposed by the laws of nature. Our experiment uses an artificial spin chain made of highly anharmonic fluxonium qubits [4] arranged on a lattice and coupled to one another by mutual inductance. While the transverse magnetic field and on-site energy can be tuned in situ, disorder and coupling strength can be adjusted at will by microfabrication enabling us to reach unprecedented parameter regimes.

A deeper understanding of the competition and resulting transitions between phases of matter could provide insights into the properties of complex materials and more generally into the many-body physics of quantum systems.

1:27PM G68.00010: Growth and preservation of entanglement in a many-body localized system  
BEN CHIARO (Presenter), University of California, Santa Barbara, BROOKS FOXEN, MATTHEW MCEWEN, JOHN M MARTINIS, AI Quantum, Google — 
We use programmable superconducting qubit quantum processors to provide a detailed survey of the many-body localized (MBL) phase for both 1D and 2D lattice geometries. We demonstrate disorder induced ergodicity breaking by studying the transport properties of excitations as the system evolves under a Bose-Hubbard Hamiltonian. Further, we use interferometric techniques to establish effective non-local interactions in our localized system. Beyond demonstrating these defining features of MBL we directly observe the slow growth of von Neumann entanglement entropy. From density matrix measurements we also compute the entanglement of formation and use this information to provide a spatial and temporal map of entanglement. Finally, starting with a maximally entangled Bell state embedded in an MBL environment, we measure the capability of an MBL system to preserve this quantum correlation and characterize its degradation in response to a remote excitation.

1:39PM G68.00011: Approximating finite-temperature dynamic correlation functions on quantum computers  
JEFFREY COHN (Presenter), IBM Research-Almaden, KHADIJEH NAJAFI, Virginia Tech, BARBARA JONES, IBM Research-Almaden, JAMES FREERICKS, Georgetown University — Dynamic correlation functions such as single particle Green's functions, linear response functions, or dynamical susceptibilities serve as a foundational tool kit for studying strongly correlated quantum systems. Ideally, a quantum computer will be able to extract these functions for systems sizes that are intractable on classical computers. When it comes to studying these functions at finite temperature the main bottleneck comes from the resource overhead and circuit complexities required in preparing each Gibbs sample. We present a framework aimed at alleviating this bottleneck by optimizing a series of approximations. Specifically, we sample from a series of time averaged embedded clusters initially in their respective local Gibbs states. After extracting each approximate dynamic correlation function we employ Richardson extrapolation where the error expanded in the series is determined by the total number of sub-clusters used in each approximation. We obtain higher order estimates for each distinct path of approximations. We can optimize even further by weighting each distinct path by how closely each path fits the proper fluctuation theorem. We demonstrate this toolbox numerically using exact diagonalization of the Hubbard model on small clusters.
1:51PM G68.00012: Band engineering for quantum simulation with superconducting circuits
CHRISTIE CHIU (Presenter), ANDREW HOUCK, Princeton University — Quantum simulation has been implemented on a variety of experimental platforms such as neutral atoms, ions, quantum dots, and superconducting circuits, each offering unique features. Superconducting circuits can and have been used to realize artificial photonic materials in a wide range of lattice geometries and graph connectivities, due to the flexibility of on-chip fabrication. In addition, photon-photon interactions are highly tunable using nonlinearities such as superconducting qubits, leveraging the vast toolkit developed for quantum computation. Here I report on recent progress towards engineering flat bands for studies of strongly correlated many-body physics.

*This research was supported by the Princeton Materials Science Postdoctoral Fellowship and the ARO MURI program.

G68.00013: Propagation and Localization of Collective Excitations on a 24-Qubit Superconducting Processor
YANGSEN YE (Presenter), University of Science and Technology of China — Superconducting circuits have emerged as a powerful platform of quantum simulation, especially for emulating the dynamics of quantum many-body systems. Here we construct a Bose-Hubbard ladder with a ladder array of 20 qubits. We then use pairs of controllable qubits to study the dynamics of the ladder model. We investigate theoretically and demonstrate experimentally the dynamics of single- and double-excitation states with distinct behaviors. We observe linear propagation of photons in the single-excitation case. The double-excitation state, initially placed at the edge, localizes; while placed in the bulk, it splits into two single-excitation modes. Our work paves the way to simulation of exotic logic particles by subtly encoding physical qubits and exploration of rich physics by superconducting circuits.

H71.00003: Hydrodynamic Transport in Near Magic Angle Twisted Bilayer Graphene*

MOHAMMAD ZARENIA (Presenter), Univ of Missouri - Columbia, INDRA YUDHISTIRA, Yale-NUS College, SHAFFIQUE ADAM, National University of Singapore & Yale-NUS College, GIOVANNI VIGNALE, Univ of Missouri - Columbia — Using the semiclassical quantum Boltzmann theory and employing the Dirac model with twist angle-dependent Fermi velocity we obtain results for the electrical resistivity, the electronic thermal resistivity, the Seebeck coefficient, and the Wiedemann-Franz ratio in near magic angle twisted bilayer graphene, as functions of doping density (around the charge-neutrality-point) and modified Fermi velocity. The Fermi velocity-dependence of the relevant scattering mechanisms, i.e. electron-hole Coulomb, long-ranged impurities, and acoustic gauge phonons is considered in detail. We find a range of twist angles and temperatures, where the combined effect of momentum-non-conserving collisions (long-ranged impurities and phonons) is minimal, opening a window for the observation of strong hydrodynamic transport. Several experimental signatures are identified, such as a sharp dependence of the electric resistivity on doping density and a large enhancement of the Wiedemann-Franz ratio and the Seebeck coefficient.

H71.00004: Detecting superconductivity out-of-equilibrium*

BENEDIKT FAUSEWEH (Presenter), Los Alamos National Laboratory, SEBASTIAN PAECKEL, ALEXANDER OSTERKORN, Institut für Theoretische Physik, Georg-August-Universität Göttingen, D-37077 Göttingen, Germany, THOMAS KOEHLER, Department of Physics and Astronomy, Uppsala University, Box 516, S-751 20 Uppsala, Sweden, DIRK MANSKE, Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, D-70569 Stuttgart, Germany, SALVATORE MANMANA, Institut für Theoretische Physik, Georg-August-Universität Göttingen, D-37077 Göttingen, Germany — Pump-probe experiments on cuprates and similar systems suggest the existence of a transient superconducting state far above the critical temperature. This poses the question how to reliably identify the emergence of superconductivity, out-of-equilibrium. In our contribution we investigate this point by studying the non-equilibrium dynamics in an extended Hubbard model and by computing various observables, which are used in theory and experiment to identify superconductivity. We specifically show, that the time-dependent optical conductivity is not sufficient to distinguish between a dynamical induced superconductor or an enhanced metallic state. In turn, we suggest to utilize time-resolved ARPES experiments in the two-particle channel to probe for superconducting signatures.

H71.00005: WITHDRAWN ABSTRACT
H71.00007: Stimulated electron-electron interaction in cavities* HONGMIN GAO (Presenter), FRANK SCHLAWIN, DIETER JAKSCH, University of Oxford — Electron interactions mediated by the exchange of virtual bosonic excitations form a central cornerstone in quantum many-body theory where they are responsible for many-body phases such as superconductivity [1,2]. More recently, interactions mediated by excitations with photonic character, such as exciton-polaritons [3,4] and transverse cavity photons [5] have also been tipped to lead to superconductivity. We propose a novel scheme to engineer stimulated electron interactions in any 2D electron system coupled to a cavity under driving. The interaction can be tuned to be attractive (or repulsive) and lead to Cooper instability at temperature up to ~1K. Our scheme opens up a new avenue for on-demand quantum material engineering.

H71.00008: First-principles study on the electronic structures of ternary TMDC alloys in monolayer and multilayer forms* JUN NARA (Presenter), WENTONG GENG, TAKAHISA OHNO, National Institute for Materials Science — Transition metal dichalcogenides (TMDCs) have attracted great attention for their potential application in many fields including light-emitting diodes and photo detectors. The possibility in controlling the stacking sequence of different kind of TMDC layers by means of van der Waals epitaxy enables us to design novel materials through electronic structure engineering. Recently, two-dimensional lateral heterostructures have been successfully synthesized by Sahoo et al. [1], providing us a new freedom in heterostructure design other than sequential stacking. We have investigated the electronic structures of a monolayer and multilayers of ternary alloys made of Mo\(_{(1-x)}\)W\(_x\)S\(_2\) by using PHASE/0 [2], a first-principles electronic structure calculation code. We obtain a direct energy band gap whose width is smaller than both MoS2 and WS2. Details of the results will be given in the presentation.

We used the NIMS Numerical Materials Simulator for the calculations.

H71.00009: Electronic states and Coulomb excitations of $\alpha$-$T_3$ zigzag nanoribbons  
PAULA FEKETE (Presenter), US Military Academy at West Point, ANDRII IUROV, Medgar Evers College of the City University of New York, GODFREY GUMBS, Hunter College of the City University of New York, DANHONG HUANG, Air Force Research Laboratory, Kirtland Airforce Base, Albuquerque, NM — We have examined all possible non-equivalent types of edge terminations for pseudospin-1 $\alpha$-$T_3$-based nanoribbons. Our results show that all of their fundamental electronic properties depend significantly on both the hopping parameter $\alpha$ and the particular geometry of their edge. For all non-equivalent edge terminations, we have calculated the electronic wave functions, Coulomb potential, and plasmon dispersion relations. We also report on the dependence of the plasmon dispersion on the electron doping concentration for zigzag edged nanoribbons.

H71.00010: Ultrafast nonlinear electron dynamics in gapped graphene*  
AHMAL ZAFAR (Presenter), SEYYEDEH AZAR OLIAEI MOTLAGH, ARANYO MITRA, FATEMEH NEMATOLLAHI, VADYM APALKOV, MARK I STOCKMAN, Georgia State University — We theoretically study the ultrafast electron dynamics in gapped graphene. Graphene consists of two equivalent sublattices and has both inversion and time-reversal symmetries. Breaking the inversion symmetry in graphene opens the bandgap and makes sublattices inequivalent. Gapped graphene is used as a model for a broad class of two-dimensional materials, including transition metal dichalcogenides. The ultrafast electron dynamics in gapped graphene is induced by a linearly polarized ultrafast optical pulse applied perpendicular to graphene monolayer. Our results show that the residual, i.e., after the pulse, conduction band (CB) population, which characterizes the irreversibility of the electron dynamics, is large and shows interference fringes in the reciprocal space. The finite bandgap in graphene makes the electron dynamics partially reversible, which manifests itself in smearing of the interference fringes in the CB population distribution.

H71.00011: Ultrafast field-driven currents in gapped graphene*  ARANYO MITRA (Presenter), SEYYEDEH AZAR OLIAEI MOTLAGH, AHMAL ZAFAR, FATEMEH NEMATOLLAHI, VADYM APALKOV, MARK I STOCKMAN, Georgia State University — We study theoretically interaction of a linearly polarized ultrashort and ultrafast optical pulse with gapped graphene monolayer. A finite conduction band population and corresponding electric currents are generated during the pulse. In gapped graphene, inversion symmetry is broken, and while one axis, is still the axis of symmetry (y-axis), the other axis (x-axis) is no longer so, which results in generation of non-trivial currents. When the incident pulse is polarized along x-axis, both the longitudinal and transverse currents are generated. Our results show that both currents strongly depend on the bandgap. The generated electric currents transfer electrical charge and make the gapped graphene electrically polarized. The transferred charge in longitudinal direction has monotonic dependence on the field amplitude and weak dependence on the bandgap, while in transverse direction, the transferred charge shows non-monotonic dependence on the field amplitude.

H71.00012: Optical absorption spectrum for $\alpha\mc{T}_3$ materials interacting with light.  DIPENDRA DAHAL (Presenter), The Graduate Center, City University of New York, GODFREY GUMBS, Physics and Astronomy, Hunter College, City University of New York, ANDRII IUROV, Physics and Astronomy, Medgar Evers College, City University of New York, DANHONG HUANG, Air Force Research Laboratory — We have investigated the optical absorption properties of $\alpha\mc{T}_3$ materials, interacting with linearly and circularly polarized irradiation. The peaks in the optical absorption spectra and the plasmon modes show strong dependence on the hopping parameter $\alpha$ and a relatively moderate dependence on the strength of light-matter interaction, as well as on the polarization of the incoming off-resonance dressing field.
Temperature dependence of van Hove singularity excitons in atom thick semiconductors*  
GARRETT BENSON (Presenter), VIVIANE ZURDO COSTA, NEAL BORDER, SHIRIN JAMALI, San Francisco State Univ, KENTARO YUMIGETA, MARK BLEI, SEFAATTIN TONGAY, Materials Science and Engineering, Arizona State University, ANDREW ICHIMURA, AKM SHAH NEWAZ, San Francisco State Univ — Atomically thin semiconducting transition metal dichalcogenides (TMDs) are emerging as a new platform for exploring two-dimensional exciton physics. These excitons play a crucial role in determining the light-matter interactions of a semiconducting material, such as absorption, photoluminescence, and electroluminescence. In addition to direct-band gap transition excitons (known as $A$- and $B$- excitons), there also exists a pair of van Hove singularity (vHS) assisted excitonic transitions, known as the $C$- and $D$- excitons. Currently it is not known how these vHS excitons modify at different temperature. To bridge the knowledge gap, we probed the temperature dependence of both direct-band gap and vHS excitons via photocurrent spectroscopy. We observed that all the excitonic peaks shift to lower energy as the temperature decreases. Moreover, we observed that the rate of shift for vHS excitons differs significantly from the rate of shift for the direct-band gap excitons. This study advances our understanding of the intrinsic properties of excitons in 2D TMDs.

Steering valley-polarized emission of monolayer MoS$_2$ sandwiched in plasmonic antennas  
TE WEN (Presenter), HU AIQIN, School of Physics, Peking University, YANG CHEN, CHENG-WEI QIU, Department of Electrical and Computer Engineering, National University of Singapore, QIHUANG GONG, GUOWEI LV, School of Physics, Peking University — Monolayer transition metal dichalcogenides (TMDCs) have intrinsic spin-valley degrees of freedom, making it appealing to exploit valleytronic and optoelectronic applications at the nanoscale. Here, we demonstrate that a chiral plasmonic antenna consisting of two stacked gold nanorods (GNRs) can modulate strongly valley-polarized photoluminescence (PL) of monolayer MoS$_2$ in a broad spectral range at room temperature. The valley-polarized PL of the MoS$_2$ with the antenna can reach up to ~48% accompanied with more than three orders of magnitude enhancement of PL intensity. Also, the $K$ and $K'$ valleys under opposite circularly polarized light excitation exhibit different emission intensities and directivities in the far-field, which can be attributed to the valley-dependent exciton modulation by the chiral antenna in both excitation and emission processes. The distinct features of the ultra-compact hybrid suggest potential applications for valleytronic and photonic devices, chiral quantum optics, and high-sensitive detection.
H71.00015: Electron transport through pair of Graphene-Superconductor junctions*
SHAHRRUKH SALIM, RAHUL SURESH MARATHE, SANKALPA GHOSH (Presenter), Indian Inst of Tech-New Delhi — Electron transport across Graphene-Superconductor (GS) junctions have recently attracted a lot of attention [1] after it was pointed out that the Andreev processes in such junction holds distinct features as compared to Andreev processes in Normal metal-Superconductor junction because of the ultra relativistic dispersion of the charge carriers in Graphene. In this work we analyze transport properties through a pair of such junctions that can be either GSG or SGS form due to Andreev and normal processes. In one part of the work we compare such transport with certain optical phenomena such as Goos-Hanchen shift [2] and discuss its experimentally verifiable features. We also investigate the formation of the Andreev Bound States (ABS) in heterojunctions like SGS, and explore its connection with the transport properties; Josephson current.

H71.00016: Strain Imaging of Laterally-Stitched Monolayers by Nonlinear Optical Microscopy*
CHUN AN CHEN (Presenter), YING-YU LAI, KUAN-CHANG CHIU, CHEN PO-HAN, YI-HSIEN LEE, YU-TING LIN, YI-CHENG CHIANG, I-TUNG CHEN, National Taiwan Normal Univ — Strain configuration is significant to crystal structure and performance of monolayer two-dimensional lattice. Heterojunction of various monolayer transition metal dichalcogenides (TMD) is emergent route to induce unique symmetry and strain configurations. Here, we realize the synthesis of diverse in-plane artificial lattice by lateral stitching of different monolayer TMD using sequential CVD growth. Highly oriented strain patterns are observed and studied by second harmonic generation imaging of the TMD multijunctions. Strain pattern with lateral and vertical heterostructures are studied using angle resolved second harmonic generation, which is practical to correlate unique properties by direct probing symmetry and strain configuration of monolayer TMDs.

H71.00017: Synthesis and enhanced magnetoresistance of WTe$_2$ single crystals*  \textbf{YU-TING LIN} (Presenter), CHUN-AN CHEN, CHEN PO-HAN, I-TUNG CHEN, YI-CHENG CHIANG, YI-HSIEN LEE, Materials Science and Engineering, National Tsing Hua University, Hsinchu 30013, Taiwan — Tungsten ditelluride (WTe$_2$) is one of the low symmetry two-dimensional materials and exhibits extremely large magnetoresistance (XMR) below 10K. Understanding of novel properties in the materials is highlighted to induce unique properties at elevated temperature. Study of the temperature dependent MR is essential for real applications and deep insights. Most reported studies on fundamental issues are mainly achieved in exfoliated WTe$_2$ (for reduced disorders) which is encapsulated with h-BN layers (for ideal interfaces). Here, we demonstrate synthesis and enhanced performances of the synthesized WTe$_2$ single crystals. Tunable thickness and high crystallinity of the WTe$_2$ are achieved using promoter-assisted CVD. A large MR of the CVD-grown WTe$_2$ is experimentally realized.

H71.00018: Carbonaceous magnetic nanocomposites*  \textbf{DEREJE SEIFU} (Presenter), Morgan State Univ, SHASHI P KARNA, WMRD, US ARL, HAIPING HONG, EE, SDSMT — Ferromagnetic nanoparticles when in proximity to low-dimension carbonaceous structures, such as 1D carbon nanotubes and 2D graphene, induce ferromagnetism in the latter through spin-orbit coupling and exchange interaction. Taking advantage of these interaction, we have created carbonaceous magnetic nanocomposites using carbon nanotubes and multilayer graphene that exhibit enhanced magnetic properties compared to the pristine nanoparticles [1-3]. The Magnetic nanoparticles studied included Fe, Fe$_2$O$_3$, Fe$_3$O$_4$, Co$_3$O$_4$, and CoFe$_2$O$_4$ on both carbon nanotubes and multilayered graphene. Structural and magnetic studies showed that magnetic enhancement occurred by proximity effect.

H71.00019: Nonlinear Electrical and Linear Optical Properties of Layered Graphene Oxide
DEJAN MAKSIMOVSKI, Colgate University, N. G. HALLFORS, Biomedical Engineering, KUST, ABDEL ISAKOVIC (Presenter), Colgate University — We measured a significant, two orders of magnitude decrease in the resistance of layered (5 - 100 nm) reduced graphene oxide. The resistance drops as the number of layers increases, lending a notion to the influence of out-of-plane transport being modulated by modifications to the changes in electronic structure, as additional layers are added. These changes are observed for line and area resistance, as well, indicating that geometry doesn't play major role. In parallel with this result, we report spectroscopic study (Raman, FTIR) on the same samples, where the ratio of spectral D (1350 cm\(^{-1}\)) and G (1580 cm\(^{-1}\)) features shows unusual dependence on the thickness (the number of layers of graphene oxide), in that it mimics the dependence of the resistance on thickness. Detailed spectroscopic study of various bonds (some sp\(^2\) related, some not) shows a number of features that are potentially relevant for explanation of observed resistance behavior. The role of carbon vacancies is also studied, showing that the bonding of molecules external to graphene oxide becomes modified in the presence of vacancies. AFM and electron microscopy studies complement these findings and show how layered graphene oxide large area, nanoscale thickness scale structures evolve with controlled defects.

H71.00020: Towards an electrically driven single photon source made from a carbon nanotube
DUBLIN NICHOLS (Presenter), DUY NGUYEN, ETHAN MINOT, Oregon State Univ — On-demand single photon sources have potential applications in quantum cryptography, quantum computing, and metrology. In particular, there is a need for devices that can be integrated into an on-chip network and can produce indistinguishable photons on-demand. Such devices would enable practical designs for all-optical quantum computers. We aim to create electrically driven single photon sources using individual semiconducting carbon nanotubes with sp\(^3\) defects. Novel aspects of our device design include integration with van der Waals heterostructures, and the use of electrostatic gating to form p-n junctions. I will show why this is a promising platform, and discuss our progress towards fabricating a working prototype.
H71.00021: Transport in armchair graphene nanoribbons and in ordinary waveguides
MUHAMMAD ZUBAIRM (Presenter), Department of physics, Concordia University, MOUSA BAHRAMI, Department of Computer Science and Mathematics, Nippising University, PANAGIOTIS VASILOPOULOS, Department of physics, Concordia University — We study dc and ac transport along armchair graphene nanoribbons using the k.p spectrum and eigenfunctions and general linear-response expressions for the conductivities. Then, we contrast the results with those for transport along ordinary waveguides. In all cases, we assess the influence of elastic scattering by impurities, describe it quantitatively with a Drude-type contribution to the current previously not reported, and evaluate the corresponding relaxation time for long- and short-range impurity potentials. We show that this contribution dominates the response at very low frequencies. In both cases, the conductivities increase with the electron density and show cusps when new subbands start being occupied. As functions of the frequency, the conductivities in armchair graphene nanoribbons exhibit a much richer peak structure than in ordinary waveguides: in the former, intraband and interband transitions are allowed, whereas in the latter, only the intraband ones occur. This difference can be traced to that between the corresponding spectra and eigenfunctions.

H71.00022: Electronic Structure Study of Halogen and Gold Halide Doped Carbon Nanotubes
MD LATIFUR RAHMAN, MD HASIBUL AMIN, AHMED ZUBAIRM (Presenter), Electrical and Electronic Engineering, Bangladesh University of Engineering and Technology — Achieving high electrical conductivity of carbon nanotubes (CNTs) through doping will facilitate its application in power transmission cable and nanoelectronic interconnects. Here, we report extremely efficient p-doping of CNT using halogen and gold halide molecules. Using ab initio theoretical calculations based on density functional theory, we investigated the effect of dopants, such as I\textsubscript{2} and AuCl\textsubscript{3}, on the electronic band structure of semiconducting and metallic CNTs. We found that both I\textsubscript{2} and AuCl\textsubscript{3} introduces states between the first Van Hove singularities of conduction and valance bands. I\textsubscript{2} was reported being an efficient dopant for CNTs. From our calculations, we confirm that large Fermi level shift occurs for both I\textsubscript{2} and AuCl\textsubscript{3} doping. Though the Fermi shift is much larger for AuCl\textsubscript{3} doping. Moreover, transmission function calculations reveal that a few fold increase in available quantum channels exists for AuCl\textsubscript{3} doping compared to I\textsubscript{2} doping. Therefore, gold halide such as AuCl\textsubscript{3} can be a perfect candidate as a dopant molecule of CNTs to produce conductors with ultra-high conductivities.
H71.00023: Investigating single-walled carbon nanotube films for LEDs and lasers*  
MARK STEGER (Presenter), BRYON LARSON, KIRA THURMAN, ANDREW FERGUSON, JEFFREY L BLACKBURN, National Renewable Energy Laboratory — Carbon nanotubes (CNT) offer interesting optoelectronic properties including engineered conductivity and tunable infrared emission. CNTs have been extensively studied as carrier transport layers for OLEDs or as single-nanotube LEDs. Here, we investigate LED and laser architectures using CNT films as a bulk active emitter layer tunable in the near IR. We investigate the intrinsic stability of the emitter layer and optimize device structure.

*This work was authored by the National Renewable Energy Laboratory, operated by Alliance for Sustainable Energy, LLC, for the U.S. Department of Energy (DOE) under Contract No. DE-AC36-08GO28308. Funding provided by the LDRD Program at NREL.

H71.00024: Phase segregation and superconductivity in Cu doped Ni$_{2-x}$Cu$_x$NbSn Heusler alloys  
BRANDON REESE (Presenter), MAHMUD KHAN, Miami University — Heusler alloys exhibit numerous exotic properties including superconductivity that can be systematically controlled via manipulation of their stoichiometry and elemental doping. It has been reported that partial substitution of Ni by Cu in Ni$_{2-x}$Cu$_x$ZrGa results in a systematic reduction of T$_{C}$. Considering this observation it is interesting to explore the effect of Cu doping on the superconducting properties of other Heusler alloys. Therefore, we have performed an experimental study on the superconducting properties of partially Cu doped Ni$_{2-x}$Cu$_x$NbSn materials. Ni$_2$NbSn has 29 valence electrons per formula unit and 7.25 valence electrons per atom. The material exhibits a superconducting phase transition at T$_{C}$ = 3.4 K. A series of Ni$_{2-x}$Cu$_x$NbSn materials were synthesized by arc-melting and annealing techniques. All materials were characterized by x-ray diffraction, dc magnetization, and transport measurements. Interestingly, a Cu concentration of 2.5% resulted in phase segregation of the system. Two superconducting transitions were observed in all compounds at temperatures near T$_{C1}$ = 17.8 K, and T$_{C2}$ = 3.4 K. Magnetization data has confirmed type-II superconductivity for each sample at both T$_{C1}$ and T$_{C2}$.

H71.00025: Gapless spin liquid state and quantum phase diagram in the spin-1/2 $J_{1}$-$J_{2}$ square Heisenberg model  WEN-YUAN LIU (Presenter), physics, Chinese Univ of Hong Kong, SHOUSHU GONG, physics, Beihang University, ZHENGCHENG GU, physics, Chinese Univ of Hong Kong — The spin-1/2 $J_{1}$-$J_{2}$ square Heisenberg model is one of the most interesting and also challenging quantum spin models, due to the strongly frustrated interactions. It is of the primary candidate models to study quantum spin liquid (QSL). Despite intensively studied in the past 30 years, the nature of the intermediate nonmagnetic phase is still under great debates. Especially, whether the intermediate phase is a QSL is currently a matter of great concern to the community. A recent DMRG calculation suggests that the intermediate region is a valence bond state. However, the DMRG method is essentially a one-dimensional method. Recently, we developed an efficient and accurate finite projected entangled pair states (PEPS) method, which can deal with a very large system in high precision. With this state-of-the-art tensor network based method, we find it is a spin liquid phase for a large region of the nonmagnetic phase, and spin correlations of the spin liquid decay in a power law form, indicating it is gapless. Methodologically, we give the first solid PEPS calculation beyond DMRG. By comparing with DMRG in details, we provide a direct numerical evidence to explicitly demonstrate the conceptual advantage of PEPS over DMRG for large 2D systems.

H71.00026: Thermodynamic properties of a spin-1/2 Heisenberg model on the triangular lattice  KAZUHIRO SEKI (Presenter), SEIJI YUNOKI, RIKEN — By using the numerically exact diagonalization technique and a block-extended version of the finite-temperature Lanczos method, we study thermodynamic properties, such as entropy, specific heat, and uniform susceptibility, of a spin-1/2 Heisenberg model on the triangular lattice with the nearest-neighbor exchange interaction $J$ and the four-spin exchange interaction $J_c$. Our calculations on small clusters containing up to 36 spins have found that, differently from the pure triangular-lattice ($J_c=0$) case, the temperature dependence of the specific heat exhibits a pronounced double-peak structure for finite and moderate $J_c/J$.

H71.00027: Monte Carlo Study of Three-dimensional Flat-Band Ferromagnetism in a Diamond Lattice*  JUNJIA ZHANG, ERIC J BOBROW (Presenter), YI LI, Johns Hopkins University — We study the p-orbital bands in the orbital-active diamond lattice. This system features doubly-degenerate flat bands at each momentum in the Brillouin zone as well as dispersive bands exhibiting nodal-line semimetal behavior. Due to the suppression of kinetic energy, strong correlation effects lead to ferromagnetism in the flat bands, which can be mapped to a modified percolation problem. We investigate the transition between the paramagnetic and ferromagnetic phases in the flat bands via Monte Carlo simulation.

*This work is supported by NSF CAREER DMR-1848349 and in part by the Alfred P. Sloan Research Fellowships.
H71.00028: A highly sensitive TES spectrometer for resonant elastic/inelastic X-ray scattering study of quantum materials  SANG JUN LEE (Presenter), SLAC - Natl Accelerator Lab, SANGJUN LEE, University of Illinois Urbana Champaign, YOUNG-IL JOE, NIST, HAI HUANG, SLAC - Natl Accelerator Lab, WILLIAM B DORIESE, NIST, JASON KNIGHT, DONGHUI LU, SLAC - Natl Accelerator Lab, JOEL N ULLOM, PAUL SZYPRYT, DANIEL SWETZ, NIST, PETER MICHAEL ABBAMONTE, University of Illinois Urbana Champaign, JUN-SIK LEE, SLAC - Natl Accelerator Lab — Resonant inelastic X-ray scattering (RIXS) as well as resonant elastic X-ray scattering (REXS) have been appreciated as compelling techniques in research of quantum materials. It is because the techniques deliver element-, site-, and valence-specific information through a resonance-enhanced photon-in/photon-out process. Conventionally, grating-based spectrometers have been used to measure the scattered photons in RIXS/REXS in the soft X-ray regime. However, we often experience a lack of sensitivity when a weak signal needs to be detected. Here, we introduce a novel method to overcome such difficulty using transition-edge sensors (TESs). A spectrometer built upon an array of TESs has detection efficiency that is orders of magnitude larger than a conventional grating spectrometer and has shown a spectral coverage broader than 1 keV and a moderate energy resolution of 1.5 eV (FWHM) at 500 eV. A TES spectrometer was recently integrated with the soft X-ray scattering setup at beamline 13-3 of the Stanford Synchrotron Radiation Lightsource (SSRL) and was successfully commissioned. In this poster, we will present new results taken with this new RIXS/REXS + TES approach. We believe that this approach can bring impacts to a wide range of quantum materials studies.

H71.00029: WITHDRAWN ABSTRACT  —

H71.00030: Evidence for effects of nitrogen exposure on the Bi$_2$Se$_3$ density of states  MICHAEL GOTTSCHALK (Presenter), Michigan State University, MAL-SOON LEE, Pacific Northwest National Laboratory, ERIC GOODWIN, Michigan State University, THOMAS CHASAPIS, MERCOURI KANATZIDIS, Northwestern University, S D MAHANTI, STUART TESSMER, Michigan State University — Bi$_2$Se$_3$ is a topological insulator widely used for scientific studies due in part to the ease with which it can be cleaved, exposing a clean surface for study. Typically the materials exhibit n-type doping attributed to selenium vacancies which results in a shift of the Dirac point to between 100 and 300 meV below the Fermi level. Using room temperature scanning tunneling microscopy (STM), we observed evidence for a shift in the expected density of states spectra when crystals first cleaved in a helium gas environment became exposed to ultra high purity N$_2$ gas. The shift brings the Dirac point 50 meV closer to the Fermi level. We will also present density functional theory calculations supporting the picture that nitrogen can bind to the selenium vacancies and shift the density of states. Finally, we will present data showing the time scale over which the exposure occurs.
**H71.00031: Measurement of fractional charge at disclination defects in higher-order topological crystalline insulators**

CHRISTOPHER PETERSON (Presenter), TIANHE LI, TAYLOR L HUGHES, GAURAV BAHL, University of Illinois at Urbana-Champaign — Topological crystalline insulators (TCIs) are known to host quantized fractional charge at boundaries and defects, which is topologically protected by bulk crystalline symmetries. Recently, this bulk-boundary correspondence was extended by the discovery of higher-order TCIs, which may host quantized fractional charge at a boundary of their boundary. Here, we use arrays of microwave resonators to experimentally study higher-order TCIs on lattices with disclination defects. Introducing a disclination defect to a finite lattice is equivalent to inserting or removing one or more sectors, changing the total number of corners and consequently introducing an overall fractional charge. Since the total charge in a lattice must remain an integer, the disclination core is expected to also host fractional charge to compensate. We experimentally measure C4-symmetric higher-order TCIs on square lattices having disclinations with positive and negative Frank angles, which respectively have 5 and 3 corners. We find that, in both cases, the disclination core does indeed host fractional charge, such that the total charge of the lattice is an integer. Furthermore, we show that there are gapless bound states associated with the defect.

*We acknowledge support from the US National Science Foundation.

**H71.00032: Topological surface states in strained Cd3As2 thin films**

PABLO VILLAR ARRIBI (Presenter), Argonne Natl Lab, TIMO SCHUMANN, SUSANNE STEMMER, University of California, Santa Barbara, ANTON BURKOV, University of Waterloo, OLLE HEINONEN, Argonne Natl Lab — Cd3As2 is a Dirac semi-metal with two Dirac nodes near the Γ point in the first Brillouin zone aligned along the crystallographic c-axis. The structure of Cd3As2 is rather complicated with a large unit cell and it is typically grown along the (112) direction, which does result in a projection of the Fermi arc states on the (112) surface. The Dirac points are protected by inversion and C4 symmetry about the tetragonal c-axis. In recent experiments, the inversion symmetry can be broken in thin films, and the C4 symmetry can be broken by a bi-axial strain perpendicular to the c-axis [1]. This brings up the question of what happens to the Fermi arc states in the ultra-thin film limit and in the presence of broken symmetries. We are using a simple description of the low energy physics to examine the behavior of the Fermi arc states. As an example, when inversion symmetry is broken, so is the symmetry of the Fermi arc states near the Dirac points, and the two-fold degeneracy of the Dirac cones is lifted.

*This work was supported U.S. Department of Energy Office of Science, Office of Basic Energy Sciences.
**H71.00033: Chiral Anomaly and Temperature Effects in Tilted Doped Weyl Semi-metals: Dichroism And Dynamic Hall Angle**

ASHUTOSH SINGH (Presenter), JULES P CARBOTTE, McMaster University

We calculate the absorptive part of the dynamic conductivity for both right and left handed circular polarized light in the Kubo formalism. Due to finite contribution from the imaginary part of Hall conductivity, we observe dichroism in certain frequency regime. Including the effect of chiral pumping creates difference in chemical potential in the positive and negative chirality nodes, which leads to additional regions of frequencies where dichroism remains finite. We have also considered the case of a non-centrosymmetric Weyl semi-metal in which the two nodes are displaced in energy by an amount ±Q₀. This also modifies the dichroism in a similar fashion. Further, with increase in temperature (T), the boundaries of the regions of finite dichroism become smeared out in energy and extend beyond their original range for T = 0 and at the same time the dichroism is reduced. When T is increased to be of the order of the chemical potential associated with the doping, the dichroism vanishes. We have also extended the work to include the frequency variation of dynamic Hall angle for both zero and finite temperature cases.

**H71.00034: Ultrafast optical current in Weyl semimetals**

FATEMEH NEMATOLLAHI, VADYM APALKOV (Presenter), MARK I STOCKMAN, Georgia State University

We study theoretically the nonlinear response of Weyl semimetals to an ultrashort optical pulse. Such strong electric field induces a finite conduction band population near the Weyl points in the reciprocal space. Also, the optical pulse causes current in the system both during and after the pulse.

**H71.00035: Sign Change in the Anomalous Hall Effect and Strong Transport Effects in a 2D Massive Dirac Metal Due to Spin-Charge Correlated Disorder***  
AYDIN KESER (Presenter), School of Physics, University of New South Wales, ROBERTO RAIMONDI, Department of Physics, Universita Roma Tre, DIMITRIE CULCER, School of Physics, University of New South Wales — The anomalous Hall effect (AHE) is highly sensitive to disorder in the metallic phase. Here we show that statistical correlations between the charge-spin disorder sectors strongly affect the conductivity and the sign or magnitude of AHE. As the correlation between the charge and gauge-mass components increases, so does the AHE, achieving its universal value, and even exceeding it, although the system is an impure metal. The AHE can change sign when the anticorrelations reverse the sign of the effective Dirac mass, a possible mechanism behind the sign change seen in recent experiments.

*This research was supported by the Australian Research Council Centre of Excellence in Future Low-Energy Electronics Technologies (Project No. CE170100039) and funded by the Australian Government.

**H71.00036: Strain-engineering of Topological Type-II Dirac Semimetal NiTe$_2$***  
ANTONIO MANESCO (Presenter), Kavli Institute of Nanoscience, Delft University of Technology, PEDRO P. FERREIRA, LUCAS EDUARDO CORRÊA, ANTONIO JEFFERSON DA SILVA MACHADO, GABRIELLE WEBER, LUIZ T. F. ELENO, University of Sao Paulo — The electronic, elastic and topological properties of the equilibrium and strained type-II Dirac semimetal NiTe$_2$ were studied within the scope of density functional theory. This bulk transition metal dichalcogenide harbor a tilted symmetry-protected Dirac cone from p-orbital bands in the vicinity of the Fermi level. The projected electronic structure and group analysis suggest that single orbital-manifold band inversion can be assigned as the mechanism behind the present topologically non-trivial states. Also, several applied strain modes are shown to be an effective route to tuning this bulk electronic trends. For instance, a small uniaxial strain along z-direction is enough to approach Dirac fermions into the Fermi energy and suppress another usual non-relativistic bands from the Fermi surface. Through our investigations, we propose a static-control of the electronic states by the intercalation of light-metal monovalent species into the van der Waals gap. We also present a low-energy effective model and discuss effects of external fields and low-dimensionality.

**H71.00037: Nonlinear Anomalous Hall Effect in Type I Weyl Metals**

AYDIN KESER (Presenter), DIMITRIE CULCER, University of New South Wales, ARC FLEET — Within the framework of linear response, Anomalous Hall Effect (AHE) in time reversal (TR) invariant systems is prohibited, yet in inversion symmetry (P) breaking system, AHE second order in the applied fields is expected.

The Fermi sea contribution to both linear and nonlinear AHE in Weyl semimetal is due to Berry dipoles and multipoles, however, in a doped metallic phase free carrier contribution at each node is large when the cone is tilted. We calculate the second order optical AHE conductivity in tilted Weyl nodes and characterize disorder contributions in the DC limit of first and second order AHE. We discuss the implications of our findings in the context of P-breaking TR-invariant system of Weyl nodes at nonzero chemical potential.

**H71.00038: Hybrid Dispersion Dirac semimetal and Hybrid Weyl phases in Luttinger Semimetals: A dynamical approach**

SAYED ALI AKBAR GHORASHI (Presenter), William & Mary — We show that hybrid Dirac and Weyl semimetals can be realized in a three-dimensional Luttinger semimetal with quadratic band touching (QBT). We illustrate this using periodic kicking scheme. In particular, we focus on a momentum-dependent drivings (nonuniform driving) and demonstrate the realization of various hybrid Dirac and Weyl semimetals. We identify a unique hybrid dispersion Dirac semimetal with two nodes, where one of the nodes is linear while the other is dispersed quadratically. Next, we show that by tilting QBT via periodic driving and in the presence of an external magnetic field, one can realize various single/double hybrid Weyl semimetals depending on the strength of external field. Finally, we note that in principle, phases that are found in this work could also be realized by employing the appropriate electronic interactions.

**H71.00040: 3D quantum Hall effect: Theories and recent progress**

FANG QIN, Southern University of Science and Technology, CHUNMING WANG, Shanghai Normal University, HAIZHOU LU (Presenter), Southern University of Science and Technology, XINCHENG XIE, Peking University — The quantum Hall effect is one of the most important discoveries in condensed matter physics. Usually, the quantum Hall effect happens in 2D. A 3D quantum Hall effect has been a long-sought phase of matter. Recently, the quantized Hall resistance has been observed 3D crystals of Cd3As2 and ZrTe5 and can be attributed to the Weyl orbit and charge density wave mechanisms, respectively. In this talk, we will introduce the theories and recent progress of 3D quantum Hall effect.
**H71.00041: Point contact Andreev reflection spectroscopy on possible chiral superconductor UTe$_2$**

SEUNGHUN LEE (Presenter), XIAOHANG ZHANG, SHENG RAN, RICHARD GREENE, University of Maryland, College Park, NICHOLAS BUTCH, National Institute of Standards and Technology, JOHNPIERRE PAGLIONE, ICHIRO TAKEUCHI, University of Maryland, College Park — Recent findings on a heavy-fermion superconductor, UTe$_2$ such as 1) an exceptionally large and anisotropic upper critical field, 2) a large residual Sommerfeld coefficient, 3) the reentrant superconducting phase in a high magnetic field, and 4) pressure-enhanced superconductivity, have attracted great attention as indication of spin-triplet superconductivity. Scanning tunneling microscopy/spectroscopy measurements and microwave surface impedance measurement on UTe$_2$ have suggested presence of the chiral edge state and normal fluid at the surface as evidence for the chiral spin-triplet pairing symmetry of the superconducting order parameter in UTe$_2$. To further investigate the superconducting order parameter, we are performing point contact Andreev reflection (PCAR) measurements on single-crystal UTe$_2$. PtIr and Nb tips are used to form N(I)/S and S(I)/S point-contact junctions, respectively. Evolution of conductance spectra as a function of temperature, magnetic field, and tip pressure will be discussed.

**H71.00042: A New Frontier in Superconductivity: a Study of Hybridized Gold Clusters**

AJIT HIRA (Presenter), JOSE PACHECO, MATILDA FERNANDEZ, BRIDGET ORTIZ, Northern New Mexico College, TOMMY CATHEY, Lockheed Information Systems — In this research we utilize a combination of the tools of ab initio quantum mechanics and the tools of molecular dynamics, the Hubbard Model to study clusters of the compounds Au$_m$X$_n$ (X = atom of a different species; 1 <= m <= 10; and 1 <= n <= 10). We also looked for enhanced absorption characteristics that have sometimes been found at sub-gap frequencies when coupling is decreased. Topological superconductors are of great interest because of the active ongoing experimental efforts to study exotic physics such as Majorana zero modes. These systems have excitations with non-Abelian exchange statistics, which can be a path to quantum information processing. Our calculations reveal two of the signatures of superconductivity at temperatures close room temperature, but not all the signatures. Further calculations are planned in attempts to place our findings on a more firm footing. Such calculations are important in light of the recent reports of room-temperature superconductivity from experimentalists in India. We also discuss the possibility of superconductivity mechanisms other than the formation of cooper pairs.

*The New Mexico AMP program, funded by the NSF, supported some of our work.*
Topological semimetals exhibiting Dirac and Weyl fermions, which support low-energy quasi-particles in condensed matter physics, have been attracting intense research interest because of the exotic properties they possess like high magnetoresistance and high carrier mobilities. The transition metal diarsenides such as MoAs$_2$ and WAs$_2$ have been reported to feature very large magnetoresistance suggesting the possibility of topological quantum state in these materials. Here, we present the systematic electronic structure measurements of TAs$_2$ (T = Mo, W) by using angle-resolved photoemission spectroscopy (ARPES) complemented by first-principles calculations. We observe a single Dirac surface state in MoAs$_2$, which switches to trivial state for different cleaving surface. Interestingly, no Dirac surface state is observed in WAs$_2$, despite its high magnetoresistance, highlighting the role of spin-orbit coupling in the electronic structure. Our study thus provides a new perspective on how cleavage plane and spin-orbit coupling drive changes in the electronic structures in low-symmetry systems.

**H71.00044: Long-Lived Quantum Well State Excitation and Surface Photovoltage Interplay in Topological Insulator**

SAMUEL CIOCYS (Presenter), ALESSANDRA LANZARA, RYO MORI, University of California, Berkeley — Topological insulators with Fermi levels doped into the bulk-gap exhibit strong surface band-bending and long-lived surface photovoltage (SPV) effects. Furthermore, in-situ surface doping of the topological insulators Bi2Se3 and Bi2Te3 can lead to strong Rashba-split quantum well states. In this study, we have combined bulk-doping and surface-doping to obtain both a strong surface photovoltage and spin-momentum locked quantum well states. Remarkably, Time- and angle-resolved photoemission spectroscopy reveals an additional pump-induced quantum well state that persists for 100s of picoseconds and coincides with the surface photovoltage, as well as time-dependent modifications to the quantum well states. Our work demonstrates that topological insulators are an exemplary foundation for tunable spin-textures with complex dynamics.

**H71.00045: Kagome bands disguised in a coloring-triangle lattice**

SHUNHONG ZHANG (Presenter), University of Science and Technology of China, MENG KANG, Wuhan University, HUAQING HUANG, University of Utah, WEI JIANG, University of Minnesota, XIAOJUAN NI, University of Utah, LEI KANG, Beijing Computational Science Research Center, SHUNPING ZHANG, HONGXING XU, Wuhan University, ZHENG LIU, Tsinghua University, FENG LIU, University of Utah — The kagome bands hosting exotic quantum phases generally and understandably pertain only to a kagome lattice. This has severely hampered the research of kagome physics due to the lack of real kagome-lattice materials. Interestingly, we discover that a coloring-triangle (CT) lattice, named after color-triangle tiling, also hosts kagome bands. We demonstrate first theoretically the equivalency between the kagome and CT lattices, and then computationally in photonic (waveguide lattice) and electronic (Au overlayer on electride Ca2N surface) systems by first-principles calculations. The theory can be generalized to even distorted kagome and CT lattices to exhibit ideal kagome bands. Our findings open an avenue to explore the alluding kagome physics.

**H71.00046: Observation of Dirac state in DySb**  
KLAUSS DIMITRI (Presenter), MD MOFAZZEL HOSEN, GYANENDRA DHAKAL, Univ of Central Florida, BAOKAI WANG, Physics, Northeastern University, FIROZA KABIR, CHRISTOPHER SIMS, SABIN REGMI, Univ of Central Florida, ERIC BAUER, FILIP RONNING, Condensed Matter and Magnet Science Group, Los Alamos National Laboratory, ARUN BANSIL, Physics, Northeastern University, MADHAB NEUPANE, Univ of Central Florida — Extreme magnetoresistance (XMR), magnetic and structural phase transition, and possible non-trivial topological phases in the rare-earth monopnictide family have recently invigorated intense research interest. Recent reports have experimentally revealed the presence of a Dirac-like semimetallic phases in some lighter rare earth monopnictide materials. Here we present a systematic ARPES study as well as first-principles calculations of DySb, a potential candidate for hosting a Dirac semi-metal phase. Our studies reveal two hole-like Fermi surface pockets present at the zone center (Gamma) point as well as two elliptical electron-pockets present in the zone corner (X) point of the Brillouin zone (BZ). Interestingly, Rashba-split states are observed at the (X) point of the BZ in a certain momentum direction, which is further supported by our first-principles calculations. A Dirac state is also observed at the (X) point of the BZ in the vicinity of the magnetic transition temperature. Our study opens a new direction to look for Dirac semi-metal states in other members of the rare earth monopnictide family.

*This project is supported by the Air Force Office of Scientific Research under award number FA9550-17-1-0415 and the National Science Foundation (NSF) CAREER award DMR-1847962.

**H71.00047: Infrared absorptions in gate-tuned twisted bilayer graphene**  
KWANGNAM YU, Univ of Seoul, NGUYEN VAN LUAN, TAESOO KIM, Center for Integrated Nanostructure Physics, Institute for Basic Science (IBS), Sungkyunkwan University, JIWON JEON, JIHO KIM, Univ of Seoul, PILKYUNG MOON, New York University Shanghai and NYU-ECNU Institute of Physics at NYU Shanghai, YOUNG-HEE LEE, Center for Integrated Nanostructure Physics, Institute for Basic Science (IBS), Sungkyunkwan University, EUNJIP CHOI (Presenter), Univ of Seoul — We show that the infrared transmission spectrum of electrically gated twisted bilayer graphene (TBG) manifests dramatic changes such as the splitting of the interlinear-band absorption step, the shift of the inter-van Hove singularity transition peak, and the emergence of a very strong intravalence (intraconduction) band transition. These anomalous optical behaviors demonstrate that non-rigid band reconstruction occurs by the ion-gel gating due to layer-dependent Coulomb screening that is confirmed by our band structure calculations. We discuss the implications of such effect on the superconductivity of TBG, and also on possible applications as electro-optical device.
We theoretically investigate periodically driven two dimensional semimetal in high frequency regime and demonstrate the possibility of realizing both Floquet Topological Insulator featuring Floquet edge states and Floquet higher order topological insulating phase, accommodating topological corner modes. Topological phase transition takes place with the external drive where Chern number changes from +1 to -1 with the change of drive amplitude in case with broken time-reversal symmetry (T) due to circularly polarized light. When discreet four-fold rotation symmetry (C_4) is broken by adding a mass perturbation alongwith broken T, the quadrupolar moment Q_{xy} is found to have a quantized value 0.5 and topological corner modes arise in the system which is characterization of second order topological insulator. The nature of the Floquet corner modes with the increase of external drive is examined.
**H71.00049: Higher-order Topological Phases in Dynamical Optical Lattices**

HAIPING HU (Presenter), George Mason Univ, BIAO HUANG, Physics and Astronomy, University of Pittsburgh, ERHAI ZHAO, George Mason Univ, W.VINCENT LIU, Physics and Astronomy, University of Pittsburgh — We propose a versatile framework to dynamically generate Floquet higher-order topological insulators by multi-step driving of topologically trivial Hamiltonians. Two analytically solvable examples are used to illustrate this procedure to yield Floquet quadrupole and octupole insulators with zero and/or \( \pi \)-corner modes protected by mirror symmetries. Furthermore, we introduce dynamical topological invariants from the full unitary return map and show its phase bands contain Weyl singularities whose topological charges form dynamical multipole moments in the Brillouin zone. Combining them with the topological index of Floquet Hamiltonian gives a pair of \( \mathbb{Z}_2 \) invariant \( \nu_0 \) and \( \nu_\pi \) which fully characterize the higher-order topology and predict the appearance of zero- and \( \pi \)-corner modes. Our work establishes a systematic route to construct and characterize Floquet higher-order topological phases.

H71.00050: Stable Higgs Modes in Fulde-Ferrell-Larkin-Ovchinnikov States*  
ZHAO HUANG (Presenter), Los Alamos National Laboratory, CHIN-SEN TING, Texas Center for Superconductivity, University of Houston, JIAN-XIN ZHU, SHIZENG LIN, Los Alamos National Laboratory — Higgs boson is an elementary particle in the Standard Model that was discovered experimentally in 2012. The Higgs boson is massive thus requiring a huge particle collider to enable its discovery. An elementary excitation, analogous to Higgs boson, can also appear in superconductors as a consequence of the U(1) symmetry breaking. Akin to its cousin in particle physics, the Higgs boson in superconductors is very massive, which renders it short lived by decaying into quasiparticle continuum. This raises a question of how to stabilize the Higgs mode in superconductors. Here we study the Higgs mode in thin-film superconductors with spatially inhomogeneous superconducting order parameter, known as the Fulde-Ferrell-Larkin-Ovchinnikov state. By deriving an effective action for the small amplitude fluctuation in the ground state manifold, we obtain the dispersion for the Higgs mode. We find that the Higgs mode becomes massless and more stable at finite momentums.

*This work was carried out under the auspices of the U.S. DOE National Nuclear Security Administration under Contract No. 89233218CNA000001. It was supported by U.S. DOE Office of Basic Energy Sciences E3B5 and in part supported by Center for Integrated Nanotechnologies, a DOE BES user facility.

H71.00051: Superconductivity Suppression in Disordered Films: Interplay of Proximity to the Two- and Three-Dimensional Localization  
DANIIL ANTONENKO (Presenter), MIKHAIL SKVORTSOV, Skolkovo Institute of Science and Technology — We revisit the problem of superconductivity suppression in homogeneously disordered thin films. Andersons theorem stating that the critical temperature is insensitive to the degree of disorder is violated in the vicinity of the Anderson localization transition. For strongly disordered films, the interplay between disorder and interaction effectively suppresses the BCS coupling constant, thereby reducing the critical temperature. For strictly 2D films, superconductivity suppression is coming from large scales (similar to the 2D localization), and summation of the leading logarithms can be performed with the help of Finkelsteins renormalization group. For thicker and sufficiently dirty films, there exists an additional effect originating from small scales (similar to the 3D localization). We calculate the corresponding contribution to the shift of the critical temperature and discuss its importance in the context of experimental situation.

H71.00052: WITHDRAWN ABSTRACT —
**H71.00053: Shape-driven conductivity in graphene**  
**BENJAMIN KATZ** (Presenter), **VINCENT CRESPI**, Pennsylvania State University — A graphene surface is presented which has a non-vanishing density of states at the Fermi level. This is driven by defects in the sheet structure: these defects are solely odd-membered rings, forced upon the system by topological constraints due to its shape, which is a series of cones and saddles. These defects sufficiently distort the electronic structure of pure graphene such that the density of states at the Fermi level is significant. The system, physically, is globally flat--there is no net gaussian curvature--and the density of states is calculated via first principles. The system further possesses multiple stable surface configurations accessible via mechanical inversion of the cones, each with different densities of states.

*Research conducted under support from the 2DCC-MIP at Penn State, funded by NSF grant DMR-1539916.*

**H71.00054: Electric-field screening in multilayer graphene**  
**NIKITA TEPLIAKOV** (Presenter), **QUANSHENG WU, OLEG V. YAZYEV**, Ecole Polytechnique Federale de Lausanne — Electronic properties of multilayer graphene are now routinely controlled using out-of-plane applied electric fields thus enabling novel electronic and optoelectronic devices. In this work, we perform first-principles calculations with explicitly applied external electric field of varying strength on a large number of multilayer graphene models including twisted configurations. We show that multilayer graphene with $N > 3$ layers features a highly nonlinear electric-field screening and nonsymmetric distribution of the electrostatic potential. We further develop a highly accurate parameterization of the tight-binding model for describing multilayer graphene that includes both the electric-field screening and crystal-field splitting effects. Our work is important for the design of devices based on multilayer graphene as it provides quantitative description of the electric-field screening in this system.

**H71.00055: First Principles dielectric spectroscopy of graphene in a tera-Hz frequency region**  
**TOMOYUKI HAMADA** (Presenter), **JUN NARA, TAKAHISA OHNO**, International Center for Materials Nanoarchitechtonics, National Institute for Materials Science — The complex dielectric function $\varepsilon_1 + i\varepsilon_2$ of graphene were calculated from its electronic structure by using a first principles broadband dielectric spectrometer *UVSOR* (Universal Virtual Spectrometer for Optoelectronic Research) [1-3]. The $\varepsilon_2$ was calculated by considering the direct inter-band transitions of electrons of graphene between its conduction and valence bands including those between the two-hold degenerated bands at its Dirac point. Calculations showed that the $\varepsilon_2$ of graphene is proportional to $1/\omega$ ($\omega$ is incident photon frequency) in a low frequency region where the electron transitions in the Dirac cone occurs and that it positively diverges as $\omega \to 0eV$. The optical spectra of graphene in a frequency region from 1 to 30 tera (T) Hz were calculated. Calculated optical absorption coefficients showed that graphene is a weak absorber of THz electro-magnetic waves. Details of calculations and calculation results will be given in the presentation.

*This work was supported by Innovative Science and Technology Initiative for Security, ATLA, Japan.*
**H71.00056: Stokes and anti-Stokes Raman scattering in mono- and bilayer graphene**  
CONG XIN (Presenter), PING-HENG TAN, State Key Laboratory of Superlattices and Microstructures, Institute of Semiconductors, Chinese Academy of Sciences — Stokes and anti-Stokes Raman spectroscopy associated with the intervalley double resonance (DR) process in carbon materials is a unique technique to reveal the relationship between their characteristic electronic band structures and phonon dispersion. Here, we report the Stokes and anti-Stokes Raman scattering of the 2D mode in pristine graphene. The excitation energy ($E_{ex}$)-dependent frequency discrepancy between anti-Stokes and Stokes components of the 2D mode ($\Delta \omega(2D)$) is observed, which is in good agreement with the theoretical results. $E_{ex}$-dependent $\Delta \omega(2D)$ is attributed to the nonlinear dispersion of the in-plane transverse optical (iTO) phonon branch near the K point, confirmed by the nonlinear $E_{ex}$-dependent frequency of the 2D mode ($\omega(2D)$) in the range of 1.58–3.81 eV. The wavevector-dependent phonon group velocity of the iTO phonon branch is directly derived from $\Delta \omega(2D)$. We also report Stokes and anti-Stokes Raman scattering of the D mode in defected graphene and the 2D mode in bilayer graphene associated with intervalley DR Raman processes.

**H71.00057: Progress in quantum transport study of magic-angle twisted bilayer/bilayer graphene**  
HYEON-WOO JEONG (Presenter), JINHO PARK, SU-BEOM SONG, JONGHWAN KIM, Pohang Univ of Sci & Tech, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, GIL-HO LEE, Pohang Univ of Sci & Tech — Magic-angle twisted bilayer/bilayer graphene (TBBG) has shown various kinds of correlated electronic phases including superconductivity, ferromagnetism, Mott insulator [1, 2]. First, we discuss our dry transfer technique for making atomically clean TBBG with so-called tear-and-stack process. In our experiment, we measured the electron-electron interaction induced Mott insulating state at half fillings. We also observed the signature of superconducting phase near Mott insulating phase, and investigated by measuring temperature dependence and magnetic field dependence of current-voltage characteristics. As twist angle uniformity is crucial to form a macroscopic superconducting phase [3], we discuss our efforts and progress in realizing more homogeneous twist angle in TBBG devices.

H71.00058: Hydrodynamic Transport Theory of a non-Galilean invariant Electron Liquid*
ANTON ANDREEV, University of Washington, Seattle, SONGCI LI (Presenter), ALEX LEVCHENKO, University of Wisconsin - Madison — We develop a hydrodynamic transport theory of a non-Galilean invariant electron liquid in the presence of smooth inhomogeneities with emphasis on graphene. We computed the transport coefficients near charge neutrality point and showed a break down of the Wiedemann Franz law, resembling the observations in Crossno et al. Science 351, 1058, (2016). We studied magnetotransport phenomena and showed that the magnetoresistance is positive and quadratic in weak fields. Lastly, we examined magnetothermal transport phenomena and derived the Nernst and Ettingshausen coefficients.

*The work was suppported by DOE-BES Award No. DE-FG02-07ER46452 (A. A), NSF Grants No. DMR-1653661 and No. DMR-1743986 (S. L and A. L).

H71.00059: Growth Evaluation of Wafer-based Au-catalyzed GaAs Nanowires on GaAs(111)B Substrates with Different Patterning Conditions using µ-Raman Characterization
SE-JEONG PARK (Presenter), Korea ITS Application R&D Center, Korea I.T.S. Co., Ltd., JEUNG HUN PARK, Andlinger Center for Energy and the Environment, Princeton University — We report the relation between the catalyst patterning conditions and the intensity of the 1st order Raman active modes in Au-catalyzed GaAs nanowires. Au-patterned GaAs(111)B substrates were prepared by e-beam Litho with varying patterning conditions and GaAs NWs were grown via VLS process using a solid-source MBE. To understand the effects of the preparation conditions and resulting morphologies on the optical characteristics of 1st order TO and LO phonon modes of GaAs, the NWs were characterized by µ-Raman and SEM as a function of the e-beam dose rate, inter-dot spacing, and pattern size. The Ensembles of single crystalline NWs covered with different Au-thickness showed a downshift and asymmetric broadening of the TO and LO phonon peaks relative to GaAs bulk modes. The TO and LO intensity were clearly increased as well as the relatively higher peak shift and broadening of Raman spectra from the 100 nm pattern in response to the dose rate change. We have shown that not only the identifications of the changes in GaAs LO and Arsenic anti-site peaks are good indicators to characterize the quality of as-grown GaAs NWs but Raman spectroscopy is a powerful tool for characterizing chemical, structural, and morphological information of as-grown NWs within the supporting substrate.
H71.00060: Enabling Novel Approach to a controlled Fabrication of Freestanding Nanomaterials using Two Direct-Writing Technologies  KEITH MCCORMACK (Presenter), NICK SCHAPER, Saint Louis University, NICK LAVRIK, IVAN KRAVCHENKO, Oak Ridge National Laboratory, MARIA F. PANTANO, University of Trento, IRMA KULJANISHVILI, Saint Louis University — Owing to their unique properties, nanoscale materials, such as nanotubes, nanowires, and 2D layered nanomaterials are emerging as key building blocks of the next generation technologies. Practical implementation of such nanomaterials necessitates their successful incorporation with well-established processes for fabrication of electrical and mechanical devices, often integrated with silicon microstructures. Typically, nanomaterials are synthesized on host substrates and transferred onto the target substrates or devices. In this work, we combine mask-free “direct-write patterning” (DWP) approach for synthesis of nanomaterials at desired locations, and the direct laser writing (DLW) technique, which is based on 2-photon polymerization, to allow for the fabrication of micro-bridge structures with sub-micrometer resolution and nanolithographic patterning of catalysts for in-situ growth of nanoscale 1D or 2D materials. We will discuss our recent results on controlled preparation of 1D and 2D nanostructures with desired morphology using DWP and DLW, as well as the characterization data from Raman, AFM, and SEM measurements. Acknowledgement. A portion of this research was conducted at the ONRL Center for Nanophase Materials Sciences, which is a DOE Office of Science User Facility.

H71.00061: Thermal Hall Effect Measurements on U\textit{Pt}$_3$*  LUKE PRITCHARD-CAIRNS (Presenter), ANDREW HUXLEY, Physics, University of Edinburgh — The heavy fermion material U\textit{Pt}$_3$ is arguably the best understood unconventional superconductor to date, and has been shown to possess multiple superconducting phases [1,2]. Despite this, the symmetry of the superconducting order parameter is still somewhat up for debate, with experimental evidence for both the $E_{2u}$ [3] and $E_{1u}$ [4] representations.

Recent theoretical work has shown that the superconducting state of U\textit{Pt}$_3$ should exhibit a measurable thermal Hall effect [5], the magnitude of which is proportional to the orbital momentum of the superconducting order parameter. This implies that the thermal Hall coefficient should change when moving between the A and B phases. Furthermore, a sufficiently accurate measurement of the thermal Hall effect may be able to distinguish between the $E_{2u}$ and $E_{1u}$ representations.

*I acknowledge studentship funding from EPSRC under the grant number EP/P013686/1.
H71.00062: Muon spin rotation and relaxation in Pr$_{1-x}$Nd$_x$Os$_4$Sb$_{12}$: superconductivity and magnetism in Pr-rich alloys* PEI-CHUN HO (Presenter), Physics, California State University, Fresno, DOUGLAS E MACLAUGHLIN, Physics, University of California, Riverside, M BRIAN MAPLE, Physics, University of California, San Diego, LEI SHU, Physics, Fudan University, ADRIAN HILLIER, ISIS Neutron and Muon Sources, Science & Technology Facilities Council, OSCAR BERNAL, Physics, California State University, Los Angeles, TATSUYA YANAGISAWA, Physics, Hokkaido University, P. K BISWAS, ISIS Neutron and Muon Sources, Science & Technology Facilities Council, JIAN ZHANG, CHENG TAN, Physics, Fudan University, SHOJI D HISHIDA, Physics, California State University, Fresno, TAYLOR MCCULLOUGH-HUNTER, Physics, Hokkaido University — The Pr-rich end of the alloy series Pr$_{1-x}$Nd$_x$Os$_4$Sb$_{12}$ has been studied using muon spin rotation and relaxation. The end compound PrOs$_4$Sb$_{12}$ is an unconventional heavy-fermion superconductor, which exhibits a spontaneous magnetic field in the superconducting phase associated with broken time-reversal symmetry. No spontaneous field is observed in the Nd-doped alloys for x ≥ 0.05. The superfluid density is insensitive to Nd concentration, and no Nd$^{3+}$ static magnetism is found down to the lowest temperatures of measurement. Together with the slow suppression of the superconducting transition temperature with Nd doping, these results suggest anomalously weak coupling between Nd spins and conduction-band states. [1]

H71.00063: Elastic properties of hidden order in URu$_2$Si$_2$ are reproduced by staggered nematic order* JARON KENT-DOBIAS (Presenter), MICHAEL MATTY, BRAD J RAMSHAW, Cornell University — We develop a phenomenological mean field theory of the hidden order phase in URu$_2$Si$_2$ as a "staggered nematic" order. Several experimental features are reproduced when the order parameter is a nematic of the B$_{1g}$ representation, staggered along the c-axis: the topology of the temperature-pressure phase diagram, the response of the elastic modulus (C$_{11}$ – C$_{12}$) / 2 above the hidden-order transition at zero pressure, and orthorhombic symmetry breaking in the high-pressure antiferromagnetic phase. In this scenario, hidden order is characterized by broken rotational symmetry that is modulated along the c-axis, the primary order of the high-pressure phase is an unmodulated nematic state, and the triple point joining those two phases with the high-temperature paramagnetic phase is a Lifshitz point.

*This research was funded in part by NSF grants DMR-1719490 and DMR-1719875.
H71.00064: Electron temperature modulation at the 2D electron system in the GaAs/AlGaAs under microwave photoexcitation*  THARANGA NANAYAKKARA (Presenter), U. KUSHAN WIJEWARDENA, ANNIKA KRIISA, SAJITH WITHANAGE, RAMESH MANI, Georgia State University, CHRISTIAN REICHL, WERNER WEGSCHEIDER, Laboratorium für Festkörperphysik, ETH Zürich — The magnetotransport measurements have been performed on the 2D electron system at GaAs/AlGaAs heterojunctions to understand the influence of the microwave photoexcitation on the spin splitting of the Shubnikov-de Haas oscillations at low temperatures (<1 K). The purpose of the study is to examine the temperature modulation of the electrons under microwave photoexcitation by examining observable spin splitting- and variation thereof under photoexcitation- at high filling factors. In this study, a multicomponent Lifshitz-Kosevevich\(^1\) type function has been applied to describe the magnetotransport data, and relevant results will be presented here.

*This work was supported by the NSF under Grant No. ECCS-1710302, and by the Army Research Office under Grants No. W911NF-14-2-0076 and No. W911NF-15-1-0433.

H71.00065: Translation symmetry broken groundstates near quantum hall edge at \(\nu = 2\)*

AMARTYA SAHA (Presenter), GANPATHY MURTHY, Univ of Kentucky — Edge reconstruction for the 2D electron gas in a magnetic field at \(\nu = 2\) has been studied by Dempsey, Gelfand, and Halperin[1], who found that when the confining potential is softened the two spin polarized channels spatially separate. Using the time dependent Hartree Fock (TDHF) method we found that the collective excitations of this type of groundstate becomes unstable if we decrease the edge potential’s slope beyond certain limit. This analysis is similar to what Franco and Brey[2] did for the \(\nu = 1\) edge. We found two groundstates, charge density wave (CDW) and spin textured edge (STE). These phases not only have lower energy but also screens the background potential better than than the earlier proposed groundstate[1]. Finally, we study the collective excitations of these phases using TDHF method.

H71.00066: Two- and three-electron bubbles in Al$_x$Ga$_{1-x}$As/Al$_{0.24}$Ga$_{0.76}$As quantum wells*
XIAOJUN FU (Presenter), QIANHUI SHI, MICHAEL ZUDOV, University of Minnesota, GEOFF C GARDNER, JOHN WATSON, MICHAEL MANFRA, Purdue University — We report on transport signatures of eight distinct bubble phases in the $N = 3$ Landau level of an Al$_x$Ga$_{1-x}$As/Al$_{0.24}$Ga$_{0.76}$As quantum well with $x = 0.0015$. These phases occur near partial filling factors $\nu \approx 0.2$ (0.8) and $\nu \approx 0.3$ (0.7) and have $M = 2$ and $M = 3$ electrons (holes) per bubble, respectively. We speculate that a small amount of alloy disorder in our sample helps to distinguish these broken symmetry state in low-temperature transport measurements.

*The work at Minnesota (Purdue) was supported by the US Department of Energy, Office of Science, Basic Energy Sciences, under Award No. ER 46640-SC0002567 (DE-SC0006671). H71.00067: Ballistic electrons splashing down in a Fermi sea of a 1-dimensional quantum Hall liquid*
RAMIRO RODRIGUEZ (Presenter), FRANCOIS PARMENTIER, SPEC, CEA, CNRS, Université Paris-Saclay, CEA Saclay, 91191 Gif-sur-Yvette cedex, France, DARIO FERRARO, Dipartimento di Fisica, Università di Genova, Via Dodecaneso 33, 16146, Genova, Italy & SPIN-CNR, Via Dodecaneso 33, 16146, Genova, Italy, PREDEN ROLLEAU, SPEC, CEA, CNRS, Université Paris-Saclay, CEA Saclay, 91191 Gif-sur-Yvette cedex, France, ULF GENNSER, ANTONELLA CAVANNA, Centre de Nanosciences et de Nanotechnologies (C2N), CNRS, Université Paris-Sud, Université Paris-Saclay, 91120 Palaiseau, France, MAURA SASSETTI, Dipartimento di Fisica, Università di Genova, Via Dodecaneso 33, 16146, Genova, Italy & SPIN-CNR, Via Dodecaneso 33, 16146, Genova, Italy, FABIEN PORTIER, SPEC, CEA, CNRS, Université Paris-Saclay, CEA Saclay, 91191 Gif-sur-Yvette cedex, France, DOMINIQUE MAILLY, Centre de Nanosciences et de Nanotechnologies (C2N), CNRS, Université Paris-Sud, Université Paris-Saclay, 91120 Palaiseau, France, PATRICE ROCHE, SPEC, CEA, CNRS, Université Paris-Saclay, CEA Saclay, 91191 Gif-sur-Yvette cedex, France — The one-dimensional, chiral and dissipationless edge channels of the quantum Hall effect are good candidates to form the electrical analogue of optical fibers, which allows to coherently manipulate the propagation of single electronic wave packets. However Coulomb interactions between neighboring edge channels can lead to energy relaxation. We explore this phenomenon by measuring the energy distribution function of quasiparticles emitted at well-defined energy in an edge channel at filling factor $\nu = 2$. Our setup relies on a pair of electrostatically defined quantum dots, used as energy-resolved emitter and detector, tunnel coupled to an edge channel. We show that, on sub-micron lengths, quasiparticles undergo a strong relaxation with a survival probability dropping exponentially with their energy. Remarkably, this relaxation preserves the position and width of the quasiparticle peak in the energy distribution function. Furthermore, at intermediate lengths, we observe a marked revival of the peak at high injection energy. Our findings are qualitatively compatible with the conventionally considered theories, however new ingredients such as dissipation seem crucial in order to provide a more quantitative comparison.

Single crystal growth of Bi2212 with different Bi/Sr ratio for terahertz waves emitters

MAYU NAKAYAMA (Presenter), TAKANARI KASHIWAGI, TAKAYUKI IMAI, SYUNGO NAKAGAWA, GENKI KUWANO, YUKINO ONO, TOMOYUKI SHIZU, YOUTA KANEKO, SHINJI KUSUNOSE, JEONGHYUK KIM, MANABU TSUJIMOTO, University of Tsukuba, TAKASHI YAMAMOTO, QuTech Delft University of Technology, HIDETOSHI MINAMI, University of Tsukuba, TAKASHI MOCHIKU, National Institute for Materials Science, HIRONORI NAKAO, Institute of Materials Structure Science, High Energy Accelerator Research Organization, KEK, HIROSHI EISAKI, SHIGEYUKI ISHIDA, The National Institute of Advanced Industrial Science and Technology, YUKIO HASEGAWA, The university of Tokyo, RICHARD KLEMM, University of Central Florida, KAZUO KADOWAKI, University of Tsukuba — The Bi-based copper oxide high-temperature superconductor Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ (Bi2212) has a nonstoichiometry composition expressed as Bi$_{2+x}$Sr$_{2-x}$CaCu$_2$O$_{8+\delta}$. We consider that the disorder of the insulating layer due to this nonstoichiometric composition (Bi/Sr) affects the CuO$_2$ layer and consequently changes in the superconducting transition temperature and the in-plane residual resistance. The intrinsic Josephson junctions (IJJs) constructed in Bi2212 have been thought to be affected by a crystallographic disorder. For the application of Bi2212 single crystals to terahertz wave emitters (Bi2212-THz emitters) based on IJJs, we evaluated the disorder mainly from the viewpoint of crystal structure. Specifically, we prepared single crystals of Bi2212 with different Bi/Sr ratio and subsequently the oxygen was controlled by post annealing. And the physical properties of the crystals have been examined by using X-ray techniques. We also study the device characteristics of Bi2212-THz emitters made by different ratio of (Bi/Sr) and the obtained results are compared at this moment. We will discuss these characteristics in details in the meeting.
H71.00069: Quantum Signatures in Superconducting-to-Normal Switching Experiments on a Multigap Superconducting Junction* ROBERTO RAMOS (Presenter), University of the Sciences, STEVEN CARABELLO, Penn State Harrisburg, JOSEPH LAMBERT, National Radio Astronomy Observatory, WENQING DAI, Apple, DANIEL CUNNANE, NASA Jet Propulsion Laboratory, QI LI, Pennsylvania State University, KE CHEN, XIAOXING XI, Temple University — We review the results of our tunneling spectroscopy experiments\(^1\) which demonstrated microwave resonant activation in a multi-gap superconductor. We had measured histograms of superconducting-to-normal switching events in hybrid Josephson heterojunctions (MgB\(_2\)/I/Pb and MgB\(_2\)/I/Sn) at sub-Kelvin temperatures. When microwaves were coupled to the junctions, we observed peaks superposed on the histograms - features consistent with microwave resonant activation. This demonstrates microwave resonant activation in a novel superconducting multigap system where one superconducting electrode is multi-gap and the other superconducting electrode is single-gap. In this system, we have observed signatures of quantum behavior such as the Lorentzian shape of the escape rate enhancement, a saturation in the width of the switching current distribution at low temperatures, and evidence of multi-photon transitions.

H71.00070: Nonlinear behaviour of confined superfluid helium.∗ EMIL VARGA (Presenter), VAISAKH VADAKKUMBATT, ALEXANDER SHOOK, JOHN DAVIS, Univ of Alberta — Superfluid Helmholtz resonators provide a versatile tool for the study of both superfluid $^4$He and $^3$He under microscopic confinement. They have proven to be effective at measuring the superfluid fraction [1] and enabled detection of emergent phases under confinement in superfluid $^3$He [2]. We extend previous experiments into the strongly driven regime where the resonance is nonlinear. The nature of the nonlinear behaviour depends on the isotope of helium, and on the phase in superfluid $^3$He.

For superfluid $^4$He, the nonlinearity is due to turbulence, which at relatively high temperatures closely approximates two-dimensional turbulence of discrete point vortices even though the confinement is significantly larger than the coherence length.

For the case of superfluid $^3$He, the coherence length is comparable to the confinement and a new phase appears [2]. Here, the qualitative nature of the nonlinearity (i.e., nonlinear dissipation vs. Duffing resonance) changes with the superfluid phase, enabling phase identification.

H71.00071: Dynamics of $^3$He in a quasi-1D environment using $^4$He-plated MCM-41: NMR Studies∗ CHAO HUAN, JOHNNY ADAMS (Presenter), MARC LEWKOWITZ, NAOTO MASUHARA, Department of Physics and NHMFL, University of Florida, DONALD CANDELA, Department of Physics and NHMFL, University of Massachusetts Amherst, NEIL SULLIVAN, Department of Physics and NHMFL, University of Florida — We utilize pulsed NMR techniques to study the dynamics of $^3$He atoms in quasi-1D. The quasi-1D structure was formed within the nanochannels of mesoporous MCM-41 plated with a monolayer of $^4$He. Measurements were carried out between 0.030K < T < 3.0K, with a $^3$He line density of 0.1Å⁻¹. Direct measurement of the nuclear spin magnetization as a function of temperature show the effect of degeneracy more pronounced in a quasi-1D system compared to 3D systems. Studies of the nuclear spin-lattice interaction show a characteristic peak at 2$T_F$, while the nuclear spin-spin interaction show unusual temperature dependencies below 0.5K.

∗This research was carried out at the National High Magnetic Field Laboratory's High B/T Facility which is supported by NSF Grant DMR 1644779 and by the State of Florida.
H71.00072: Enhancement of critical current density in a superconducting NbSe₂ step junction  
XIN HE (Presenter), YAN WEN, CHENHUI ZHANG, ZHIPING LAI, King Abdullah Univ of Sci & Tech (KAUST), EUGENE M CHUDNOVSKY, Physics Department, Lehman College and Graduate School, XIXIANG ZHANG, King Abdullah Univ of Sci & Tech (KAUST) — We investigate the transport properties of a NbSe₂ nanodevice consisting of a thin region, a thick region and a step junction. We find the critical current density has similar values for both the thin and thick regions away from the junction, while the critical current density of the thin region of the junction increases to approximately 1.8 times as compared with the values obtained for the other regions. We attribute such an enhancement of critical current density to the strong vortex pinning at the surface step.

H71.00073: Optimizing the Lumped Element Resonator via changing the total capacitance and the coplanar waveguide distance for effective magnon-photon coupling*  
YUZAN XIONG (Presenter), Electronic and Computer Engineering, Oakland University, YI LI, TOMAS POLAKOVIC, RALU DIVAN, JOHN PEARSON, Argonne National Laboratory, HONGWEI QU, Electronic and Computer Engineering, Oakland University, ZHILI XIAO, WAI-KWONG KWOK, Argonne National Laboratory, WEI ZHANG, Electronic and Computer Engineering, Oakland University, VALENTYN NOVOSAD, Argonne National Laboratory — Controllable superconducting quantum circuits with strong coupling strength is a key ingredient in the study of magnon-photon coupling in hybrid magnonic systems. The circuit's impedance is a crucial factor for optimizing the magnon-photon coupling as it strongly affects the current-flow pattern. Here, we explore the low-impedance lumped element resonator which is capacitively side-coupled to the signal line of a coplanar waveguide, by altering key parameters that were characterized with a triple-axis vector magnet at 1.5 K. The resonance frequencies are found to be inversely proportional to the circuit's total capacitance. The coupling strength is mostly affected by the distance between them. We identified a critical coupling strength, which suggests an optimal quality-factor along with a minimum insertion loss. Our studies reveal an alternative route to increase the susceptibility of magnon-photon coupling.

**H71.00074: Transfer of Electron Exergy and Thermal Energy in Magnetic Field**

ANDREI SERGEEV (Presenter), US Army Rsch Lab - Adelphi, MICHAEL REIZER, 5614 Naiche Rd., Columbus, OH 43213, USA — Electrons placed in magnetic field create magnetization currents with kinetic and magnetic energy, which is an important part of the electron exergy. Even in the presence of an external thermal field the magnetization currents are dissipationless and, therefore, they do not produce entropy. However, temperature dependence of magnetization involve the magnetization currents into thermal phenomena in rather sophisticated way, which includes transformations of bulk currents into surface currents and interaction between magnetization currents. We review and revise the transfer of electron exergy and thermal energy in magnetic field, including Poynting vector, Onsager relations, Nernst and Ettingshausen effects in superconductors. Recent experiments with single magnetic vortices directly confirm our theoretical conclusions.

*The work is supported by the Army Research Laboratory. Research of AS was accomplished under Cooperative Agreement No. W911NF-18-2-0222.*

**H71.00075: Dependence of physical properties on Bi/Sr ration and oxygen content of Bi$_{2+x}$Sr$_{2-x}$CaCu$_2$O$_{8+\delta}$**

SYUNGO NAKAGAWA (Presenter), TOMOYUKI SHIZU, Univ of Tsukuba, HIRONORI NAKAO, Institute of Materials Structure Science, High Energy Accelerator Research Organization, TAKANARI KASHIWAGI, MAYU NAKAYAMA, JEONGHYUK KIM, TAKAYUKI IMAI, MANABU TSUJIMOTO, Univ of Tsukuba, YUKIO HASEGAWA, The university of Tokyo, SHIGEYUKI ISHIDA, HIROSHI EISAKI, The National Institute of Advanced Industrial Science and Technology, TAKASHI MOCHIKU, National Institute for Materials Science, KAZUO KADOWAKI, Univ of Tsukuba — In order to extract the fundamental physical properties of high transition temperature (high-$T_c$) superconductors, one needs to take account of the details of real materials which possibly affect their properties. In the case of Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ (Bi2212), non-stoichiometry due to the intersubstitution between Bi and Sr atoms exists, yielding its composition Bi$_{2+x}$Sr$_{2-x}$CaCu$_2$O$_{8+\delta}$. Accordingly, the number of hole carries ($n_h$) as well the magnitude of chemical inhomogeneity depends on $x$ and $\delta$ (oxygen content). In order to evaluate the precise $x$- and $\delta$- dependence of the physical properties, high-quality single crystals of Bi2212 with $x=0.10, 0.15,$ and 0.20 were grown by the Travelling-Solvent Floating Zone (TSFZ) method. The $\delta$ values were systematically changed by annealing the as-grown crystals under various conditions. To evaluate $n_h$, we performed XAFS measurements, in which the pre-peak intensity of the oxygen K-edge absorption spectra is known to a measure of $n_h$. We have successfully established the relationship between $n_h$ and $T_c$ of the Bi2212 system with different amount of chemical inhomogeneity ($x$'s). The details of these characteristics will be presented in the meeting.
H71.00076: In-plane ordering of O vacancies in a high-\(T_c\) cuprate superconductor with compressed Cu-O octahedrons: an automated cluster expansion study  
YUNHAO LI  
(Presenter), SHIQIAO DU, ZHENGYU WENG, ZHENG LIU, Tsinghua University — A recently discovered 73K cuprate superconductor \(\text{Ba}_2\text{CuO}_{4.5}\) implies that intact CuO\(_2\) planes are not absolutely necessary in achieving high-T\(c\) superconductivity. Featuring an exceptional Jahn-Teller distortion, wherein the CuO\(_6\) octahedrons are compressed along the \(c\) axis, O vacancies in this material prefer to reside in the CuO\(_2\) plane, which significantly modify the 2D square lattice. By combining first-principles total energy calculation with the automated structure inversion method, the effective cluster interactions of O vacancies are mapped out. Around \(\delta=0.8\), where the superconductivity was observed experimentally, we predict that the O vacancies form a long-range order, which slice the CuO\(_2\) plane into 1D chains and two-leg ladders. The latter was not known to exist in other cuprates. A Monte Carlo simulation is performed based on the effective cluster interaction model, showing that such an ordering pattern is stable up to \(~900\) K. Our results put forth a concrete structural basis to discuss the underlying superconducting mechanism.

H71.00077: Superconductivity in PbBe Multilayer Thin Film*  
THOMAS NOTT (Presenter), JAMES G STOREY, JEFFERY TALLON, JOHN KENNEDY, Victoria Univ of Wellington — It was recently proposed by X. H. Zheng et al [1], that hetero-structures of Pb and Be would exhibit high-temperature superconductivity at 36K due to Beryllium's high Debye temperature and low mass. To investigate this we have alternately grown thin films of Pb and Be in a layered structure by the use of a vacuum evaporator. Layers were approximately 10nm each for a total film thickness of <100nm. Magnetisation measurements show a transition at \(~10\)K, slightly above the bulk T\(c\) of Pb, which persists to fields significantly higher than the critical field of Pb. This shows promise for Pb-Be layered systems and may be further improved with thinner, higher quality layers.

*Funded by the Macdiarmid Institute of New Zealand
H71.00078: Pressure effects on superconductivity and anomalous transition in triangular lattice CuIr$_2$Te$_4$* 

HUNG-DUEN YANG (Presenter), HUNG-CHENG WU, YI-CHIEH CHUNG, TING-WEL GUO, ZONG-HENG YANG, D. CHANDRASEKHAR KAKARLA, Natl Sun Yat Sen Univ, LIANGZI DENG, MELISSA GOOCH, CHING (PAUL) W CHU, Texas Center for Superconductivity, University of Houston — Geometrical spin-frustrated systems play an important role in condensed matter physics. Recently, a proposed charge-density-wave (CDW) along with superconductivity (SC) in CuIr$_2$Te$_4$ was reported [1] through the resistivity and magnetization measurements. It motivated us to further study the competitions between CDW and SC under external hydrostatic pressure. The CuIr$_2$Te$_4$ was synthesized by the solid-state reaction method and characterized using X-ray diffraction (XRD) and magnetization measurements. XRD pattern confirmed the major phase of CuIr$_2$Te$_4$ and the anomalous transition ($T_s \sim 200$ K) along with SC transition below $T_c \sim 3$ K in zero-field-cooling cycle was observed. The preliminary results are in agreement with the previous report [1]. Under the external pressure, both transitions ($T_s$ and $T_c$) exhibit a systematic change, suggesting that a significant competition between anomalous transition and SC occurs in CuIr$_2$Te$_4$. The nature of anomalous transition in CuIr$_2$Te$_4$ will be discussed.

H71.00079: Structure and magnetism of Fe$_{68.8}$Pd$_{31.2}$*

ANUPAM SINGH (Presenter), SANJAY SINGH, School of Materials Science and Technology, Indian Institute of Technology (BHU), Indian Institute of Technology (BHU), RAJEV RAWAT, UGC-DAE Consortium for Scientific Research, Indore, DHANANJAI PANDEY, School of Materials Science and Technology, Indian Institute of Technology (BHU), Indian Institute of Technology (BHU) — Fe-Pd based magnetic shape memory alloys show magnetic as well as structural (martensitic) transition [1]. In the martensite phase these alloys exhibit large magnetic field induced strain about $\sim 3\%$ due to which these alloys can be used as magnetic actuators [2]. We present here the results of sample preparation, compositional analysis, X-ray diffraction (XRD) measurements and magnetic measurements. The sample is prepared by arc-meting technique and composition (Fe$_{67.4}$Pd$_{32.6}$) was verified through Energy Dispersive Analysis of X-rays. The Rietveld refinement shows that room temperature structure is cubic with space group Fm-3m and exhibit tetragonal phase at low temperature. The martensite transition observed around temperature T$\sim 235$ K, where a sharp drop in the magnetization is observed and also confirmed by low temperature XRD. A very low thermal hysteresis of the martensite phase transition makes this system important for various applications.

**H71.00080: Tuning the electronic and magnetic properties of Heusler alloys: A theoretical and experimental investigation**

DANIEL WINES (Presenter), FATIH ERSAN, Univ of Maryland-Baltimore County, RABIN MAHAT, SHAMBHU K KC, SUDHIR REGMI, UPAMA KARKI, University of Alabama, PRAHALAD PADHAN, Indian Institute Of Technology, ARUNAVA GUPTA, PATRICK LECLAIR, University of Alabama, CAN ATACA, Univ of Maryland-Baltimore County — Half metallic Heusler alloys have attracted recent attention because they are suitable materials for information storage and spintronics applications. This work presents a detailed experimental and theoretical study on a series of Fe$_{3-x}$V$_x$Ge, Fe$_{3-x}$Cr$_x$Ge, Co$_2$Fe$_{1-x}$V$_x$Ge, and Co$_2$$_{2-x}$V$_x$FeGe (0 ≤ x ≤ 1) Heusler alloys. To study these alloys, we used the cluster expansion formalism, which uses density functional theory (DFT) calculated energies as a training set, and ultimately gives us the energetics of an alloyed system as a function of concentration. We employed DFT calculations at the GGA and GGA+U level to calculate the energetic stability and the structural, electronic, mechanical and magnetic properties of each alloyed system at specific alloying ratios. Experimental measurements for these materials such as stability, lattice parameter and magnetic moment are in agreement with our calculations. Our results also confirm the half metallicity of certain alloyed materials. The findings of this study not only confirm previous experimental measurements, but can aid future experimentalists and manufacturers in the synthesis of other Heusler alloys with specific desired properties.

**H71.00081: Structure-Property Relationships in Nanocarbon-Al Composites Made by an Electrocharging Assisted Process**

MADELINE MORALES (Presenter), XIAOXIAO GE, CHRISTOPHER KLINGSHIRN, Materials Science & Engineering, University of Maryland, College Park, DANIEL COLE, US Army Research Laboratory, Aberdeen Proving Ground, LOURDES SALAMANCA-RIBA, Materials Science & Engineering, University of Maryland, College Park — Carbon nanostructures are a growing area of research due to their excellent mechanical, electrical and thermal properties. Electrocharging assisted processing of a novel class of materials, termed “covetics,” presents a practical option for macroscale production of nanocarbon-metal composites. This process incorporates carbon on the order of a couple weight percent in metals where carbon solubility is in the low ppm range. Increased tensile strength and electrical conductivity have been measured in Al covetics; however, there is minimal understanding of the structure-process-property relationship and there is high variability in measured properties among trials. We have found that the activated carbon precursor is converted to sp$^2$ graphitic carbon with increased crystallite size. XRD and XPS show no measurable formation of carbide phases. The local electromechanical behavior measured by nanoindentation and AFM gives insight into a fundamental understanding of the improved properties in covetics, and is used to improve the fabrication process for maximal increase in electrical conductivity and tensile strength.

*Funded by DOE-EERE grant DE-EE0008313. Sponsored by the Army Research Laboratory under Cooperative Agreement W911NF-19-2-0291.
**H71.00082: Ab initio investigation of solid-solid interfaces**  
MICHAEL WOODCOX (Presenter), MANUEL SMEU, Binghamton University — Because a material can be engineered to satisfy a particular need through alloying, there are other properties of that material that may not be fully understood, or may be ignored entirely. While these materials may standalone as an excellent solution to a particular problem, when they interact with other materials it may drastically alter their effectiveness. In this work, we have used density functional theory (DFT) and *Ab Initio* Molecular Dynamics (AIMD) to investigate solder-substrate interfaces. This method is being developed to provide fundamental understanding of the atomic-scale interactions occurring at the solder joints and the impact that they have on the strength and stability of the interface. Using first principles to explore these larger systems we hope to provide a level of insight into the nature of soldering, the formation of intermetallic compounds, and an enhanced resolution of forces at the interface that would help to optimize industrial needs while also exploring the limits of system sizes that can be investigated using these methods.

**H71.00083: Magnetic and Microstructure Properties of Co-doped rapidly solidified Ni\textsubscript{50}Mn\textsubscript{25-x}Co\textsubscript{x}Ga\textsubscript{25} Heusler alloys**  
IMADDIN AL-OMARI (Presenter), Dept. of Physics, Sultan Qaboos University, Muscat PC 123, Oman — Cobalt-doped melt-spun ribbons of Ni\textsubscript{50}Mn\textsubscript{25-x}Co\textsubscript{x}Ga\textsubscript{25} were prepared to study the influence of cobalt on the magnetic properties of the NiMnGa based Heusler alloy. Bulk specimens were also prepared for a comparative study. The bulk specimens and the melt spun ribbons were annealed at 900 deg. C for 5 hours followed by quenching. Microstructural studies revealed an extensively twinned structure which is beneficial for magnetic field induced strain. The magnetization measurements showed a reduction in the moment with an increase in the cobalt content from 78.4 emu/g to 52.7 emu/g for Co (x=6) and Co (x=10), respectively. A reduction was also observed in the T\textsubscript{C} when cobalt content was increased from Co (x=6) (T\textsubscript{C} =386K) to Co (x=10) (T\textsubscript{C} =263K).

*We thank Sultan Qaboos University for the support provided during this study.*
H71.00084: Local structure analysis of long-period stacking ordered (LPSO) structure phase-containing Mg alloys by X-ray absorption spectroscopy*  MAIKO NISHIBORI (Presenter), KOHEI FUJINO, KAKERU NINOMIYA, Kyushu Univ — Long-period stacking (LPSO) type Mg alloy [1] has the structure modulation and concentration modulation of the atomic arrangement in long period, and is different from the hcp structure which is a pure Mg crystal structure. In LPSO-Mg alloy, kinks are formed due to the introduction of a significant difference in grain orientation in the crystal accompanying plastic deformation, which leads to material strengthening. However, the mechanism of kink formation and its strengthening has not yet been clarified. In this study, the changes in the local structure of solid solution atoms during the formation of LPSO-phase and the kink deformation were investigated by x-ray absorption spectroscopy. As a result, the central atom of L12 cluster of LPSO-phase contained in Mg alloy was identified, and the possibility of re-diffusion of solid solution atoms by kink deformation was suggested.

*Materials were provided by Prof. K. Hagiwara of Osaka University, Prof. M. Yamasaki and Prof. Y. Kawamura of Kumamoto University. XAS measurements were performed at SPring-8 BL27SU (2019B1433, 2019B1765) and SAGA-LS BL11 (1905029F). This work was supported by MEXT/JSPS KAKENHI, Grant Numbers JP19H05130.

H71.00085: Characterization of Fatigue with the Field Theory of Deformation and Fracture
CONOR MCGIBBONEY (Presenter), SANICHIRO YOSHIDA, NAOYA FUJISHIMA, SHUN TAKAHASHI, Chemistry and Physics, Southeastern Louisiana University, TOMOHIRO SASAKI, Mechanical Engineering, Niigata University — We conducted physical experiments with metal specimens undergoing fatigue loading. Using the optical interferometric technique Electronic Speckle-Pattern Interferometry (ESPI) we analyzed the temporal behavior of the displacement pattern formed while the specimen was experiencing cyclic loads. In traditional Fatigue Analysis of aircraft wings, cracks are formed due to oscillatory loads, these cracks propagate through a structure, and a failure occurs when stresses on these cracks are above a material's ultimate strength. ESPI data from our physical experiments indicates that shear instability is related to dislocation dynamics and it can be observed by unstable temporal behavior of the displacement field, leading us to a more formal physical description of fatigue. From the viewpoint of wave dynamics described by the Field theory of Deformation and Fracture we can describe the transition from deformation to fracture in solids. Deriving field equations that govern the displacement field of solids under deformation, we conducted numerical simulations based on our physical experiments. Our hypothesis is that the Field Theory of Deformation and Fracture characterizes fatigue on a fundamental theoretical level.
H71.00086: Non-noble metal Ni-Mo alloys with special electronic structure as a cocatalyst for alternative Pt in photocatalysis*  XIN HAN (Presenter), LIN AN, CHENGYI HOU, QINGHONG ZHANG, HONGZHI WANG, College of Materials Science and Engineering, Donghua University — Noble metals are often used as cocatalysts in photocatalysis due to their special electrical properties. However, the high cost of noble metals severely limits the development and application of photocatalytic technology. Therefore, the development of non-noble metal cocatalysts is of great significance in the field of photocatalysis. In this work, noble-metal-free Ni-Mo alloys with different Ni/Mo ratios were developed and used as cocatalyst to replace the noble metal Pt using g-C$_3$N$_4$ as a substrate. Experimental results show that the optimal Ni$_4$Mo$_6$/g-C$_3$N$_4$ photocatalyst has a photocatalytic H$_2$ production rate of up to 1785 μmol/g/h, which is about 37 times higher than that of pure g-C$_3$N$_4$, and comparable to that of the Pt/g-C$_3$N$_4$. The improved photocatalytic performance can be attributed to the presence of Ni-Mo alloys with special electronic structure, which effectively promotes the separation of photogenerated e$^-$/h$^+$ pairs.

H71.00087: Non-saturating, Sub-Liner Magnetoresistance in bulk Ge$_2$Sb$_2$Te$_5$*  MING YIN (Presenter), BRANDON LACEY, Benedict College, LEI WANG, Yale University, TIMIR DATTA, Univ of South Carolina — Phase Change materials (PCM) rapidly and reversibly switch or transform between amorphous and crystalline states. This microscopic repositioning of the system in the lattice level may give rise to large macroscopic differences in physical properties; these changes in technologically important electrical, thermal and optical parameters were discovered in 1960's. Ambient temperature operable PCM's are utilized in electronic flash memory drives and in optical data storage devices. Previously we have reported on a well-known PCM alloy Ge$_2$Sb$_2$Te$_5$; where, based on Noritheim-Gorter like scaling between Seebeck coefficient (S) and electrical conductivity (σ) we have argued the existence of two distinct types of scattering. Here we report the high magnetic field magnetoresistance in poly-crystalline specimens Ge$_2$Sb$_2$Te$_5$, especially in the low temperature regime. We observe a relatively strong increase in the ohmic resistance in response to the applied magnetic field, about 150% increase between 0 - 18 T. The transport data can be precisely described by empirical functions, however, the behavior does not follow the well-known Kholer's rule. Overall, the field dependence is sub-linear but does not quite saturates up to 18 T even in the sub-kelvin range.

*DOE DE-NA0002630
H71.00088: Charge transport properties of ZnO, MgO, and CdO alloys* NICK BOECKER (Presenter), MACK ADRIAN DELA CRUZ, GARY PENNINGTON, Towson Univ — Monte Carlo based simulations of charge transport are used to investigate how important electrical properties of doped monoxide metals can be manipulated through alloying. Results include the effects of phonon, impurity, and alloy scattering on the carrier mobility in alloys of ZnO, MgO, and CdO. The electronic structure of the alloys is determined using the virtual crystal approximation and the non-local empirical pseudopotential method, which agrees well with electronic experimental data of these materials. Results have potential applications in optoelectronic devices.

*We acknowledge support from NSF Grant DMR 1709781 and from the Jess and Mildred Fisher College of Sciences and Mathematics at Towson University.

H71.00089: Temperature dependence of the anomalous Nernst effect in a Ni-Mn-Ga system* AVIRUP DE (Presenter), IISER Pune, SANJAY SINGH, School of Materials Science and Technology, IIT BHU, SUNIL NAIR, IISER Pune — Ni-Mn-Ga alloys, well-known for showing large magnetic shape memory effect, undergoes various phase transitions upon cooling, sensitive to their compositional variations. In this work, we report a detail investigation of the off-stoichiometric Ni$_{1.95}$Mn$_{1.05}$Ga through various magnetic, electronic, and thermal characterizations. Of particular, anomalous Nernst effect (ANE) studies are presented for the first time in these class of material, revealing that the ANE is very sensitive across the pre-martensitic transition in comparison to other transport measurements. With the ANE being sensitive to changes at the Fermi surface, we infer the link of structural modulations with the modulation of the Fermi surface via its nesting features. Moreover, the large ANE-signal at room temperature and the significant drop across the martensitic transition could also be promising for many spintronics applications.

H71.00090: Effect of heat treatment on current induced mixed dynamic metal-insulator phase in needle-like VO$_2$ single crystals.  BERTINA FISHER (Presenter), LARISA PATLAGAN, GEORGE M. REISNER, Technion - Israel Institute of Technology — Sliding domains in the current induced mixed Metal-Insulator phase of VO$_2$ single crystals are very sensitive on the crystal quality. Following measurements aimed to test this sensitivity were performed on an initially virgin needle-like crystal:
1. d.c. I-V measurements under steady state conditions (adequate load resistance in the NDR regime) carried out at ambient temperature on a VO$_2$ single crystal under the microscope while sliding domains were recorded on videos.
2. R(T) measurements during three heating-cooling cycles between room temperature and 355 K.
3. Repeated d.c. I-V measurements under same conditions as in 1 with video recording of sliding domains.

The results show:

a. Slow cycling through the transition have a healing effect on the sample: R(T) becomes reproducible and the activation energy in the insulating state is highest.
b. The damping term in $u(J)$ ($u$-sliding velocity and $J$-current density) after heat treatment, is practically zero in contrast to its finite value before.
c. The energetics of sliding domains emission, determined by $P(f)$ ($P=IV$- the power, $f$-the frequency) shows that the energy per domain emission decreases with increasing $f$ before heat treatment, but remains high and constant thereafter. This motivates studying samples with controlled imperfections.

H71.00091: Effect of heat treatment on the current induced dynamic mixed metal-insulator phase in needle-like VO$_2$ single crystals.  BERTINA FISHER (Presenter), LARISA PATLAGAN, GEORGE M. REISNER, Technion - Israel Institute of Technology — Sliding domains in the current induced mixed metal insulator phase of VO$_2$ single crystals are very sensitive on the crystal quality. Following measurements aimed to test this sensitivity were performed on an initially virgin needle-like crystal:

2. R(T) measured during three heating-cooling cycles between room temperature and 355 K.
3. Repeated d.c. I-V measurements under same conditions as in 1 with video recording of sliding domains.

The results show:

a. Slow cyclings through the transition have a healing effect on the sample: R(T) becomes reproducible and the activation energy in the insulating state is highest.
b. The damping term in $u(J)$ ($u$-sliding velocity and $J$-current density) after heat treatment, is practically zero in contrast to its finite value before.
c. The energetics of sliding domains emission, determined by $P(f)$ ($P=IV$- the power, $f$-the frequency) show that the energy per domain emission decreases with increasing $f$ before heat treatment, but remains high and constant thereafter. This motivates studying samples with controlled imperfections.
H71.00092: Mottness Collapse in 1T-TaS$_{2-x}$Se$_x$ Transition-Metal Dichalcogenide: An Interplay between Localized and Itinerant Orbitals*  
SHUANG QIAO (Presenter), Beijing Computational Science Research Center, XINTONG LI, Tsinghua University, XIANHUI CHEN, Nanjing University, JIAN WU, YAYU WANG, ZHENG LIU, Tsinghua University — The layered transition-metal dichalcogenide 1T-TaS$_2$ has been recently found to undergo a Mottinsulator-to-superconductor transition. By combining scanning tunneling microscopy measurements and first-principles calculations, we investigate the atomic scale electronic structure of the 1T-TaS$_2$ Mott insulator and its evolution to the metallic state upon isovalent substitution of S with Se. We identify two distinct types of orbital textures—one localized and the other extended—and demonstrate that the interplay between them is the key factor that determines the electronic structure. In particular, we show that the continuous evolution of the charge gap visualized by scanning tunneling microscopy is due to the immersion of the localized-orbital-induced Hubbard bands into the extended-orbital-spanned Fermi sea, featuring a unique evolution from a Mott gap to a charge-transfer gap.

H71.00093: Evolution of the metallic state of LaNiO$_3$ with thickness as observed with β-detected NMR  
VICTORIA KARNER (Presenter), ARIS CHATZICHRISTOS, DAVID L CORTIE, DEREK FUJIMOTO, ROBERT F KIEFL, University of British Columbia, PHILIP C. P. LEVY, TRIUMF, RYAN M. L. MCFADDEN, University of British Columbia, GERALD MORRIS, MATT PEARSON, MONIKA K STACHURA, TRIUMF, GEORG CHRISTIANI, FRIEDERIKE WROBEL, BERNHARD KEIMER, EVA BENCKISER, ALEXANDER BORIS, Max Planck Institute for Solid State Research, W ANDREW MACFARLANE, University of British Columbia — A unique set of electronic and structural conditions allow for high-$T_c$ superconductivity in the cuprates.

It has been postulated that LaNiO$_3$/LaMO$_3$ (M = Al, Ti, Ga) superlattices (SLs) could share enough of these properties to support a related superconducting state[1]. LaNiO$_3$ is the only one of the rare-earth nickelates (RNiO$_3$) that remains a paramagnetic metal at all temperatures.

Here, we present β-detected NMR measurements on LaNiO$_3$/LaAlO$_3$ SLs. Specifically, we will address the evolution of the metallic phase of LaNiO$_3$ with decreasing sample thickness.

Polariton Optical Transistor based on a MoSe$_2$-WS$_2$ Heterogenous Bilayer embedded in an Optical Microcavity at Room Temperature*  

PATRICK SERAFIN (Presenter), GERMAN KOLMAKOV, New York City College of Technology — Exciton polaritons in an optical microcavity were shown to be a platform for the design of working elements for optical transfer and processing circuits such as optical transistors and switches. In this report, we considered a three-way superposition of cavity photons, direct excitons and indirect excitons in a bilayer semiconducting system; that is, exciton dipolaritons. Using the forced diffusion equation, we studied the room-temperature dynamics of dipolaritons in a transition-metal dichalcogenide (TMD) heterogeneous bilayer embedded in an optical microcavity. Specifically, we considered a MoSe$_2$-WS$_2$ heterostructure, which encompasses Y and Ψ-shaped channels guiding the dipolariton propagation. We demonstrated that optical signals propagating in the channels can be effectively redistributed between the branches of the channels by applying the driving voltage \( \sim 2\)V/mm to one of the TMD layers. Our findings open the route to the design of an efficient room temperature polariton based optical transistor.

Polariton Formation and Propagation in an Optical Microcavity with Embedded Transition Metal Dichalcogenide with Disorder*  

SHAINA E RAKLYAR (Presenter), YAMUNA PAUDEL, New York City College of Technology, YURI LVOV, Rensselaer Polytechnic Institute, DAVID WAYNE SNOKE, University of Pittsburgh, GERMAN KOLMAKOV, New York City College of Technology — Transition-metal dichalcogenides (TMD) provide a platform for optoelectronic applications at room temperatures due to strong light-matter interactions and exciton stability. By considering the coupled dynamics of cavity photons and TMD excitons, we numerically studied exciton-polariton formation and propagation in an optical microcavity with an embedded TMD layer. Specifically, we studied the case where the TMD excitons are affected by a short-scale (10-100 nm) random potential due to the interactions with the environment inside the cavity. To characterize the stability of the polaritonic states in the system, we numerically calculated the energy of eigen modes in a cavity as a function of the wave number, \( E(k) \). In our poster, we present our findings and, in particular, we discuss the crossover from the polaritonic modes formed at weak disorder to strongly broadened photonic and excitonic modes at strong disorder. We also discuss the polariton formation and propagation in a cavity where the TMD layer is non-uniform and consists of a set of separate, topologically disconnected microflakes.

H71.00097: Peculiar electron-phonon coupling in hBN/WS$_2$ heterostructures* MIAO-LING LIN (Presenter), State Key Laboratory of Superlattices and Microstructures, Institute of Semiconductors, Chinese Academy of Sciences, Beijing 100083, China, YU ZHOU, HAI LI, Key Laboratory of Flexible Electronics and Institute of Advanced Materials, Jiangsu National Synergetic Innovation Center for Advanced Materials, Nanjing Tech University, 30, WANG YAO, Department of Physics and Centre of Theoretical and Computational Physics, University of Hong Kong, Hong Kong, China, PING-HENG TAN, State Key Laboratory of Superlattices and Microstructures, Institute of Semiconductors, Chinese Academy of Sciences, Beijing 100083, China — The electron-phonon coupling (EPC) in materials is the key to the fundamental research, underlying many novel quantum behaviors. van der Waals heterostructures (vdWHs) provide new platform to reveal the intrinsic interactions between electrons and phonons. Here we report the cross-dimensional EPC between the three-dimensional (3D) layer-breathing (LB) phonons in a thick hBN/WS$_2$ vdWH up to hundreds of layers and two-dimensional (2D) electrons of its few-layer WS$_2$ constituent. New LB modes are resonantly enhanced in hBN/WS$_2$ vdWHs when the excitation energy approached the C exciton energy of WS$_2$ constituent. This cross-dimensional EPC strength is consistent with the phonon wavefunction projection between the layer-extended bulk-like LB modes in hBN/WS$_2$ vdWHs and the LB modes strongly coupled with the C exciton in the corresponding standalone WS$_2$ flakes, which can be further confirmed by the interlayer bond polarizability model in vdWHs. This work suggests additional possibilities to manipulate EPC in vdWHs for new quantum phenomena.

**H71.00098: Nano-lasing from Zn-doped GaAs nanowires on Iron (Fe) substrate**

GYANAN AMAN (Presenter), Department of Electrical Engineering and Computer Science, University of Cincinnati, Cincinnati, OH 45221, U.S.A, CHIAWEI TU, Department of Physics, University of Cincinnati, Cincinnati, OH 45221, U.S.A, MYKHAYLO LYSEVYCH, HOE TAN, CHENNUPATI JAGADISH, Department of Electronic Materials Engineering, Research School of Physics and Engineering, Australian National University, Canberra ACT, 0200, Australia, HEIDRUN SCHMITZER, Department of Physics, Xavier University, Cincinnati, OH 45207, MARTIN FRAENZL, Department of Physics, University of Leipzig, 04103 Leipzig, Germany, MARC CAHAY, Department of Electrical Engineering and Computer Science, University of Cincinnati, Cincinnati, OH 45221, U.S.A, HANS PETER WAGNER, Department of Physics, University of Cincinnati, Cincinnati, OH 45221, U.S.A — We investigated optically pumped lasing from highly zinc-doped GaAs nanowires (NWs) on an iron (Fe) substrate at 5 K cryostat temperature. The conically shaped GaAs NWs possess an 8 nm thick Al$_2$O$_3$ layer around it to reduce Schottky band-banding. The NWs were optically excited with 150 fs laser pulses generated from Ti-Sapphire centered at a wavelength of 720 nm. The lasing output versus excitation power (L-L) of the lasing NWs shows the characteristic S shaped curve. Lasing NWs on Fe have a length of more than 4 µm with tip and base diameters of ~300 and~500 nm, respectively. Shorter NWs did not provide sufficient modal gain to exceed the plasmonic losses in the Fe film. The emission spectrum reveals two or three longitudinal modes, which resonate within the gain spectrum. The threshold power for NW lasers on Fe substrate were higher than for NWs on Au or glass due to significantly higher losses in the Fe film. FDTD simulations reveal that the hybrid plasmonic mode of lasing NWs on Fe has a predominantly photonic character. In a further step, we will investigate if an applied magnetic field influences the lasing behavior in GaAs NWs on Fe substrate.

**H71.00099: Epsilon-near-zero plasmonic nanowaveguides to achieve efficient resonance energy transfer and quantum entanglement**

CHRITOS ARGYROPOULOS (Presenter), YING LI, University of Nebraska - Lincoln — The efficient entanglement and strong resonance energy transfer between optical dipole emitters randomly distributed in a photonic system over extended time periods and long distances remain a key challenge. The main reasons are the extremely weak dipole-dipole interactions, decoherence, and dephasing between the emitters caused by radiative and nonradiative losses. We tackle this problem by proposing a practical plasmonic waveguide system to engineer both the temporal (entanglement) and spatial (resonance energy transfer and superradiance) coherent emission dynamics by an ensemble of emitters. The proposed nanoscale plasmonic waveguide system, that exhibits an effective epsilon-near-zero (ENZ) response, can simultaneously achieve the efficient inter-emitter entanglement and large enhancement of resonance energy transfer in elongated distances, long time scales, and, even more importantly, independent of the emitters' nanoscale positions [Y. Li, A. Nemilentsau, and C. Argyropoulos, “Resonance Energy Transfer and Quantum Entanglement Mediated by Epsilon-Near-Zero and Other Plasmonic Waveguide Systems,” Nanoscale 11, 14635, 2019]. Our presented results are expected to be useful for the future quantum communication and information plasmonic-based nanodevices.

H71.00100: Tuning photonics structure by integrating with 2D materials* KAI HAO (Presenter), ROBERT SHREINER, AMY BUTCHER, ALEXANDER A HIGH, University of Chicago — Monolayer transition metal dichalcogenides (TMDCs) exhibit exceptional coupling to light and large electrical tunability, which make them perfect candidates for optoelectronics applications. We demonstrate the integration of TMDCs and photonic structures. Due to the strong coupling between the TMDCs and tightly confined light fields, the optical properties of the photonic structures are significantly modified. By electrically tuning the TMDCs, we can control the coupling between them and realize on demand tuning of the photonic structures. This study sheds light on future applications of TMDCs in on-chip photonics.

H71.00101: Critical tuning of Luttinger liquid interactions through control of ion impurities* ANDREAS MICHELESEN (Presenter), Physics and Materials Research Science Unit, University of Luxembourg, MANUEL VALIENTE, Institute for Advanced Study, Tsinghua University, NIKOLAJ TZINNER, Aarhus Institute for Advanced Studies, Aarhus University, ANTONIO NEGRETTI, Zentrum für Optische Quantentechnologien, Fachbereich Physik, Universität Hamburg — Introducing ionic impurities into a Luttinger liquid (LL) of neutral atoms modifies the effective atom-atom interaction. By tuning characteristic parameters of the system, namely the short range phases of the atom-ion polarization potential and the relative density of atoms and ions, we show that the effective interaction of the LL can be tuned across a wide spectrum of values. Remarkably, the introduction of ions allows an interaction which is initially attractive to become effectively repulsive. We demonstrate this by finding the ground state of an atom-ion system using DMRG and extracting the LL parameter and the speed of sound. The LL theory models the low-energy physics of a gas of cold atoms in a one-dimensional trap, and thus these results are experimentally relevant for the recent advances in bringing different atomic species together in hybrid quantum systems.

**H71.00102: First-principles calculation of the electronic nematicity in FeSe**

XUANYU LONG (Presenter), Institute for Advanced Study, Tsinghua University, SHUNHONG ZHANG, International Center for Quantum Design of Functional Materials (ICQD), Hefei National Laboratory for Physical Sciences at the Microscale, and Synergetic Innovation Center of, FA WANG, International Center for Quantum Materials, School of Physics, Peking University, ZHENG LIU, Institute for Advanced Study, Tsinghua University — We report a density functional theory calculation that produces the nonmagnetic electronic nematic state in FeSe, without explicit breaking of the tetragonal lattice symmetry. We incorporate orbital-resolved interactions by +U and hybrid functional, and precondition the initial wavefunction to find local energy minima with spontaneous symmetry breaking. The lowest-energy nematic state we find features an anti-ferro hexadecapolar charge order, instead of a simple ferro-orbital order, which is important to produce the correct Fermi surface topology in FeSe. We propose that the weak inversion symmetry breaking induced by this multipolar order can be detected by high-precision measurement of the band dispersion as well as second-harmonic generation.

**H71.00104: Bogoliubov-de Gennes analysis of superconducting gap in nanowires and nanotubes**

GERMAN LOPEZ (Presenter), CHUMIN WANG, Instituto de Investigaciones en Materiales, Universidad Nacional Autonoma de Mexico — Most quantum theories of superconductivity have been formulated in the reciprocal space by taking the advantage of translational symmetry. Such symmetry is absent in many nanostructured superconductors, whose study requires a real space approach such as the Bogoliubov-de Gennes formalism [1]. In this work, the inhomogenous superconducting gap [2,3] in nanostructures is studied by means of a simple attractive Hubbard model. The results show a unique critical temperature for each nanostructure despite the variation of its local superconducting gap and the spectral average of such gap over the chemical potential location grows when its coordination number diminishes. The latter suggests that the superconductivity in nanostructures could be enhanced by the quantum confinement of electrons, which reduces its kinetic energy and accentuates the potential one.

This work was partially funded by UNAM-PAPIIT-IN110020 and CONACyT-252943. Computations were performed at Miztli of DGTIC-UNAM. G.E.L. thanks the support from UNAM-PAEP 2020.

H71.00105: Effects of percolation on the superconductor-insulator transition in thin films*
KRISTINE UNG, ROBERT LYNN, SAMUEL SHAPIRO, NINA MARKOVIC (Presenter), Goucher College —
Thin films of superconductors are known to undergo a quantum phase transition into the
insulating state as a function of disorder and magnetic field, but the nature of the transition has
been debated for decades. In order to investigate the effects of percolation and rare
superconducting regions on the superconductor-insulator transition in thin films, we have
fabricated a series of nanostructured films with controlled vicinity to the percolation threshold.
We will show how the measurements of resistance as a function of temperature and magnetic
field correlate to the physical texture of the films.

H71.00106: Domains, Domain Walls, and Phase Slips in the Nearly-Commensurate Charge
Density Wave Phase of 1T-TaS₂*
BONING YU (Presenter), MANOJ K SINGH, BISHNU SHARMA, MICHAEL BOYER, Clark University —
The nearly-commensurate charge density wave (CDW) state of 1T-TaS₂ consists of hexagonally ordered domains. Within these domains, the CDW state is
commensurate with the lattice. However, there are domain walls which include phase slips in the
CDW state between neighboring domains. Here we combine our scanning tunneling microscopy (STM) data of the nearly-commensurate CDW state with computer simulations to study, at the
atomic-scale, domains, domain ordering, and phase slips at domain walls in 1T-TaS₂. In particular,
we examine how these features manifest themselves in Fourier transforms of STM topographic
images.

*We acknowledge support from NSF Grant number DMR-1904918.
**H71.00107: The low frequency surface slasmons in multicoaxial NIM cables: Zero magnetic field**

MANVIR KUSHWAHA (Presenter), Rice Univ, BAHRAM DJAFE.I-ROUHANI, Physics, USTL — 
Employing an elegant response function theory\(^1\)\(^-\)\(^3\), which does not require matching of the messy boundary conditions, 
we investigate the surface plasmon excitations in the multicoaxial cylindrical cables made up of negative-index metamaterials. The multicoaxial cables with dispersive metamaterial components exhibit a 
rather richer (and complex) plasmon spectrum with each interface supporting two modes: one 
TM and the 
other TE for \(m\neq 0\) (the integer order of the Bessel function). The cables with nondispersive 
metamaterial components 
bear a different tale: they do not support simultaneously both TM and TE modes over the whole 
range 
of propagation vector. The computed local and total density of states enable us to substantiate 
spatial positions 
of the modes in the spectrum. Such quasi-one-dimensional systems as studied here should prove 
to be the milestones 
of the emerging optoelectronics and telecommunications systems. 1. M.S. Kushwaha, B. Djafari- 
Rouhani, 

**H71.00108: Harnessing the magneto-optics in quantum wires for observing the quantum pinch effect**

MANVIR KUSHWAHA (Presenter), Rice Univ — Here, we report on a two-component, 
cylindrical, quasi-one-dimensional quantum plasma subjected to a \textit{radial} confining harmonic 
potential and an applied magnetic field in the symmetric gauge. It is demonstrated that such a 
system as can be realized in semiconducting quantum wires offers an excellent medium for 
oberving 
the quantum pinch effect at low temperatures. An exact analytical solution of the problem allows 
us to make significant observations: surprisingly, in contrast to the classical pinch effect, the 
particle density as well as the current density display a \textit{determinable} maximum before 
attaining a minimum at the surface of the quantum wire. The effect will persist as long as the 
equilibrium pair density is sustained. Therefore, the technological promise that emerges is the 
route to the precise electronic devices that will control the particle beams at the nanoscale\(^1\). 1. 
M.S. 
**H71.00109: Nanoporous Metal Foams as Efficient Particulate Filters**

JAMES MALLOY (Presenter), KAI LIU, Georgetown University — Nanostructured metal foams offer exciting potential for applications in diverse fields such as catalysts, electronics, heat exchange, structural materials, and filtration due to their extremely high surface area to volume ratios. We have achieved a variety of metallic foams using electrochemical methods, with strong mechanical stability and tunable porosity and density (0.1%-30% of bulk density) [1]. Uniaxial compression tests reveal significantly varying structural strengths depending on the relative density. Additional physical characteristics and applications have been explored. We have also investigated using such foams as efficient filtration membranes for micron and sub-micron sized particles. Over 99% of airborne micron sized particles are found to be filtered after passing through just 1 mm of metallic foam. The foams are also found to be effective for filtering out deep submicron particles. The pressure drops across the foams are found to vary depending on the bulk density of the foam; with the lower density foams being comparable to commercial HEPA filters.

*This work has been supported by the Georgetown Environmental Initiative Impact Program.

**H71.00110: Sub-5 nm patterning via self-assembly and template-assisted assembly of colloidal nanocrystals**

AUSTIN KELLER (Presenter), CHERIE KAGAN, CHRISTOPHER B MURRAY, DIAN, University of Pennsylvania — We explore using colloidal lithography and conventional fabrication tools for patterning substrates at and below the 5 nm scale. Our processing pathway combines bottom-up methods using inorganic nanocrystal (NC) synthesis and self-assembly techniques with top-down nanofabrication techniques. A pattern is established by the size, shape, and arrangement of discrete NC building-blocks, and the density is determined by the interparticle spacing of each element. The collective arrangement of each element sets the ensemble pattern, where each NC serves as a discrete hard etch mask. We explore self-assembly at a liquid-air interface and topographic template-assisted capillary assembly methods to establish the NC patterns. This pattern is transferred to the underlying substrate using inductively couple plasma reactive ion etching, and a selective chemical wet etch is used to remove any remaining mask material after pattern transfer. The NC systems explored are Fe₃O₄ spheres, TiO₂ rods, and GdF₃ rhombic plates with CF₄ and Cl₂ plasma etch chemistries. The goal of our pathway is to implement innovative processing methods into already well-established fabrication methods and technology, while maintaining process simplification and enabling wider access to patterning at the deep nanoscale.
H71.00111: Skyrmions on a sphere shell  DELARAM NEMATOLLAHI (Presenter), KIERAN MULLEN, Univ of Oklahoma — Skyrmions, as small electronic spin-structures, provide a window into strongly interacting many electron systems. The existence of these spin-textures has been studied in quantum Hall (QH) ferromagnets, in which the kinetic energy of the electrons is quenched by the strong external magnetic field. The large angular momentum (l) single particle states on the surface of a sphere are similarly degenerate in energy as a function of their z component (m) for fixed (l). This makes electrons on a sphere an interesting system for studying spin textures. Using Hartree-Fock theory, we initially force a skyrmionic texture on the system by applying a small “scaffolding” field that couples to the spins to produce a texture and investigate the stability of the spin-structure as the field goes to zero. We study the dependence of the skyrmion stability on the number of electrons, the choice of interactive potential, and material parameters.

H71.00112: Metallic density of states in the spin liquid RuCl$_3$.*  ANDREAS RYDH, university of stockholm, ALI BANGURA, Natl High Magnetic Field Lab, KIMBERLY MODIC, max planck dresden, GREGORY SCOTT BOEBINGER, Natl High Magnetic Field Lab, BRAD J RAMSHAW, Cornell, ROSS MCDONALD, Los Alamos Natl Lab, ARKADY SHEKHTER (Presenter), Natl High Magnetic Field Lab — We use resonant line-width spectroscopy and SiN nanocalorimeters to measure specific heat of a small (~1μg mass) RuCl$_3$ sample. The low-temperature limit of C/T is metallic-like, with an extrapolated Sommerfeld coefficient corresponding to a density of states of about 100 mJ/molK$^2$, consistent with Majorana fermions of about 10meV bandwidth. We discuss the field- and angular evolution of this metallic density of states. Finally we examine thermodynamics of the AFM boundary, as well as AFM spin waves in RuCl$_3$.

*NSF through DMR-1157490

H71.00113: Heat Capacity Studies of Nano-Confined Argon*  ERIN MARLOWE (Presenter), Indiana Univ - Bloomington — The effect of confinement on the thermodynamic properties and phase transitions of liquids and solids in confinement has been of long-standing interest and recent interest has focused on the effects of dimensionality. Hydrogen has been of interest due to the importance of quantum effects, in particular zero-point motion, and has been studied extensively in a variety of porous media. Argon is a good model for hydrogen as it will exhibit similar behaviors, in general, to hydrogen. Furthermore, it is important to understand the behavior of noble gasses in confinement as it may be useful for understanding gasses like hydrogen. Templated porous materials, such as MCM-41, provide an attractive model system for studying the effects of confinement due to their highly uniform one-dimensional pores with variable pore size. Unfortunately, the minimum pore diameter is typically limited to a few nanometers which limits our ability to approach the one-dimensional limit. We will present measurements of the heat capacity of argon confined in MCM-41.

H71.00114: Effects of Metamaterial Engineering on Properties of Ultrathin Layers of NbTiN

JONATHON CARTELLI (Presenter), WILL KORZI, Department of Physics Astronomy and Geosciences, Towson University, ANNE-MARIE VALENTE-FELICIANO, Jefferson Lab, JOSEPH PRESTIGIACOMO, MICHAEL OSOFSKY, United States Naval Research Laboratory, IGOR SMOLYANINOV, Saltenna LLC, VERA N SMOLYANINOVA, Department of Physics Astronomy and Geosciences, Towson University — Application of the metamaterial dielectric function engineering is capable of enhancing superconducting properties in type I superconductors such as aluminum and tin, leading to the tripling of the critical temperature $T_c$ in Al-Al$_2$O$_3$ epsilon near zero (ENZ) core-shell metamaterial superconductors. Similar effects have been observed in hyperbolic (superconductor/dielectric) metamaterials [1]. Here, we report on the effects of metamaterial dielectric function engineering on superconducting properties of ultrathin layers of NbTiN. NbTiN/AlN multilayers with varied number of layers and layer thicknesses were fabricated. Dielectric constants of these metamaterials were measured via polarization reflectometry will be reported. Correlation of the results of the transport measurements and the hyperbolic properties of the multilayers will be discussed.

H71.00115: Introducing a new noncentrosymmetric superconductor: Zr$_3$Ir

SAJILESH K P (Presenter), PHYSICS, IISERB, D SINGH, P. K BISWAS, muon, ISIS pulse neutron and muon source, R P SINGH, PHYSICS, IISERB — An intrinsic momentum dependent antisymmetric spin-orbit coupling (ASOC) in noncentrosymmetric (NCS) systems arising due to lack of inversion center in the crystal structure gives way to numerous unusual superconducting properties [1]. The Fermi surface in these systems becomes nondegenerate in the presence of spin-orbit coupling, giving a plausibility to form an admixed superconducting order parameter. This breaks the conventional notion of even parity spin-singlet and odd parity spin-triplet order parameter, leading to the high upper critical field, anisotropic superconducting gap, and time-reversal symmetry breaking [1]. We report a new NCS compound Zr$_3$Ir, crystallizes in a tetragonal $\alpha$-V3S structure. The magnetization, specific heat, and muon spin rotation confirm s-wave superconductivity, having a transition temperature $T_c = 2.3$ K. Muon spin relaxation confirms the preservation of time reversal symmetry in the superconducting ground state [2].

Probing the superconducting ground state of noncentrosymmetric superconductors using muon spectroscopy: A case of Re-based compounds

DEEPAK SINGH (Presenter), Rutherford Appleton Lab, R P SINGH, Department of Physics, Indian Institute of Science Education and Research Bhopal, India, ADRIAN HILLIER, P. K BISWAS, Rutherford Appleton Lab, SOURAV MARIK, Laboratory Crismat, UMR6508 CNRS, Normandie University, France, SAJILESH K P, Rutherford Appleton Lab — Noncentrosymmetric superconductors (NCSs) with broken inversion symmetry has a direct influence on the superconducting properties of the system. In particular, NCSs with α-manganese structure has attracted much attention recently, after the discovery of time reversal symmetry breaking (TRSB) in all the members of the Re$_6$X (X = Ti, Hf, Zr) family [1,2]. Its persistence and the independent nature of the particular transition metal, points to a key role played by Re. To test such a hypothesis, and to ascertain the possible relevance of the noncentrosymmetric structure to TRSB in Re-based NCSs, we proceeded with a twofold study. On one hand, we studied the Re$_6$X family of compounds using muon spectroscopy, whereas, on the other hand we also studied the NbOs$_2$ compound, which doesn't contain Re as the primary element and adopts similar α-Mn structure with superconducting transition temperature $T_c = 2.7$ K [3]. The results of muon spin relaxation/rotation measurements strongly suggests that the local electronic structure of Re is crucial for understanding the TRSB superconducting state in Re$_6$X.

Physical properties of (Mn$_{1-x}$Fe$_x$)Si at x=0.15 along the critical trajectory

ALLA E PETROVA, Institute for High Pressure Physics, SERGEY YU GAVRILKIN, Lebedev Physical Institute, DIRK MENZEL, Technische Universität Braunschweig, SERGEI STISHOV (Presenter), Institute for High Pressure Physics — We report results of studying the magnetization, specific heat and thermal expansion of a single crystal with nominal composition (Mn$_{1-x}$Fe$_x$)Si with x=0.15. We found no thermodynamic evidences in favor of a second order phase transition in this material. The trajectory corresponding to the present composition of (MnFe)Si is a critical one, i.e. approaching quantum critical point at lowering temperature, but some properties may feel the cloud of helical fluctuations bordering the phase transition line.

*AEP and SMS greatly appreciate financial support of the Russian Foundation for Basic Research (grant No. 18-02-00183) and the Russian Science Foundation (grant 17-12-01050).
Investigation of quantum criticality in $\alpha$-RuCl$_3$ by means of dilatometry

ANJA WOLTER, SEBASTIAN GASS, LAURA T. CORREDOR, VILMOS KOCSIS (Presenter), Leibniz Institute for Solid State and Materials Research Dresden, LUKAS JANSSEN, MATTHIAS VOJTA, Institute of Theoretical Physics, Technical University of Dresden, PAULA J KELLEY, STEPHEN E NAGLER, Neutron Scattering Division, Oak Ridge National Laboratory, DAVID MANDRUS, Material Science and Technology Division, Oak Ridge National Laboratory, BERND BUECHNER, Leibniz Institute for Solid State and Materials Research Dresden — The quantum spin liquid candidate $\alpha$-RuCl$_3$ shows field-induced quantum criticality around $\mu_0 H_c \sim 7$-8 T, where the antiferromagnetic zigzag phase is suppressed [1,2]. Such behavior can be studied via the characteristic divergence in the temperature and field dependence of the Grüneisen parameter [3]. Here, we present high-resolution thermal expansion $\alpha$, magnetostriction $\lambda$, and specific-heat ($C_p$) measurements, performed on single crystals of $\alpha$-RuCl$_3$. The length changes were measured parallel to the $c$ axis stacking direction for magnetic field perpendicular to the $c$ axis up to 15 T. The extracted Grüneisen parameter $G = \alpha / C_p$ shows typical hallmarks for quantum critical behavior, with $G$ diverging in a characteristic manner at $\mu_0 H_c = 7.8(1)$ T. Furthermore, our thermodynamic investigations show clear evidence for the existence of three different low-temperature phases in the examined field range in line with recent magnetocaloric and neutron diffraction measurements [4]. We present calculations for thermal expansion and Grüneisen parameter in a minimal lattice model.

Percolation and Quantum Criticality: a New Universality Class

SEAN FAYFAR (Presenter), ALEX BRETAÑA, WOUTER MONTFROOIJ, Physics, University of Missouri Columbia, THOMAS HEITMANN, The Missouri Research Reactor, University of Missouri Columbia — We present the results of computer simulations on a class of percolation systems that form a new universality class. We show the results for the critical exponents for this new class, based on simulations of two- and three-dimensional lattices consisting of half a billion sites, and discuss the ensuing modified scaling laws. This new percolation system, dubbed Protected Percolation, differs from standard site percolation in that once a cluster breaks off the percolating cluster, its sites become protected and cannot be removed; thus, only sites from the lattice spanning cluster can be removed. This restriction closely mimics the situation in chemically doped quantum critical systems where isolated magnetic clusters are protected from (further) Kondo screening. Initial results indicate that Protected Percolation violates the Harris Criterion, which leads to a natural explanation as to why universal critical exponents for quantum phase transitions have been elusive.
H71.00120: Validity of Harris criterion for two-dimensional quantum spin systems with quenched disorder* JHAO-HONG PENG (Presenter), LENG-WEI HUANG, DENG-RUEI TAN, FU-JIUN JIANG, National Taiwan Normal Univ — Inspired by the recent results regarding whether the Harris criterion is valid for quantum spin systems, we have simulated a two-dimensional spin-1/2 Heisenberg model on the square lattice with a specific kind of quenched disorder using the quantum Monte Carlo (QMC) calculations. The considered quenched disorder has a tunable parameter $0 \leq p \leq 1$ which can be considered as a measure of randomness. Interestingly, when the magnitude of $p$ increases from 0 to 0.9, at the associated quantum phase transitions the value of the correlation length exponent $\nu$ grows from a number compatible with the O(3) result 0.7112(5) to a number slightly greater than 1. In other words, by varying $p$, $\nu$ can reach an outcome between 0.7112(5) and 1 (or greater). Moreover, among the studied values of $p$, all the associated $\nu$ violate the Harris criterion except the one corresponding to $p=0.9$. Considering the form of the employed disorder here, the above described scenario should remain true for other randomness if it is based on the similar idea as the one used in this study. This is indeed confirmed by our preliminary results stemming from investigating another disorder distribution.

H71.00121: Percolation Physics in doped and stochioetric Quantum Critical System ALEX BRETAÑA (Presenter), SEAN FAYFAR, WOUTER MONTFROOIJ, Physics, University of Missouri - Columbia, THOMAS HEITMANN, The Missouri Research Reactor, University of Missouri - Columbia — We argue that spontaneous fragmentation of the magnetic lattice in strongly correlated electron systems close to the quantum critical point accounts for most of the observed non-Fermi liquid behavior. Upon cooling, magnetic fragmentation of the Kondo lattice is caused by a distribution of Kondo temperatures, which in turn originate from small variations in interionic separations (0.05-0.1 Å). This temperature-dependent fragmentation transforms the magnetic lattice to a percolation system resulting in the creation of isolated clusters which dominate the low-temperature response of quantum critical systems. We argue the validity of this new scenario for the physics near a QCP using literature data on systems where interionic distances have been modified by means of chemical doping (e.g., UCu$_4$Au) as well as stoichiometric systems where zero-point phonons are responsible for such variations (e.g., CeRu$_2$Si$_2$). The percolation physics describing QCP-systems represents a new universality class (see Fayfar et al.). This new class appears to violate the Harris criterion, thereby providing a natural explanation for the lack of universality of the critical exponents observed in QCP-systems.
Many-Body Localization in Central Spin.* MARCOS TRIVELATO (Presenter), CARLOS EGUES, Sao Carlos Institute of Physics at the University of Sao Paulo, JOHN SCHLIEermann, Institute for Theoretical Physics, University of Regensburg, JOAO VITOR IGNACIO COSTA, Sao Carlos Institute of Physics at the University of Sao Paulo — We investigate many-body localization in a periodic one dimensional Heisenberg chain, with a central spin interacting equally with each spin in the chain. The chain is subject to a uniaxial quenched disorder field. Apart from a detailed analysis of the phase diagram, we study the time evolution of nonlocal out-of-time-ordered correlators to diagnose the information scrambling in the dynamics of the system.

*This work was supported by the Brazilian agencies CNPq, CAPES and FAPESP grant 2016/08468-0.

Multi-Layer Restricted Boltzmann Machine Representation of 1D Quantum Many-Body Wave Functions HUAN HE, YUNQIN ZHENG (Presenter), ANDREI BERNEVIG, Princeton University, GERMAN SIERRA, Universidad Autónoma de Madrid, Instituto de Física Teórica, UAM-CSIC — We consider representing two classes of 1D quantum wave functions of spin systems, including the AKLT and CFT correlator wave functions, in terms of multi-layer restricted Boltzmann machines. In our prescription, the AKLT wave function can be exactly represented by a 2-layer restricted Boltzmann machine with five hidden spins per visible spin. The construction can be generalized to prove that any MPS wave function on \( N \) unit cells with finite bond dimension can be approximated by a 2-layer restricted Boltzmann machine with \( O(N) \) hidden spins within an error which scales linearly with \( N \). The Haldane-Shastry wave function or a chiral boson CFT correlator wave function, as any Jastrow type of wave functions, can be exactly written as a 1-layer Boltzmann machine with \( O(N^2) \) hidden spins and \( N \) visible spins. Applying the cumulant expansion, we further find that the chiral boson CFT correlator wave function (with small vertex operator conformal dimension \( \alpha \), i.e., \( \alpha < 0.1 \)) can be approximated, within 99.9\% accuracy up to 22 visible spins, by a 1-layer RBM with \( O(N) \) hidden spins. The cumulant expansion also suggests that the hidden spins of the restricted Boltzmann machine can be interpreted as the conformal tower of the chiral boson CFT on the cylinder.
H71.00124: Puzzling "bad metal" resistivity and optical conductivity of normal-state cuprates: an emergent Bose liquid perspective  
LONG ZOU, Shanghai JiaoTong University, ZIJIAN LANG, Tsung-Dao Lee Institute & Shanghai JiaoTong University, SHENGTAO JIANG, Shanghai JiaoTong University, WEI KU (Presenter), Tsung-Dao Lee Institute & Shanghai JiaoTong University — We investigate anomalous normal-state in-plane resistivity and optical conductivity of cuprates by using multi-orbital bose-liquid model. Specifically, we assume that the charge carriers in cuprate are tightly bound pre-formed pairs. We show the low-energy optical spectrum involving both intra- and inter-band excitation. While inter-band excitation explain the continuous spectrum and its contribution around the van-Hove singularities of the pre-formed pairs can reproduce the experimental observed onset near 1000cm⁻¹, the intra-band excitation will mainly contributes to low frequency conductivity and gives rise to linear resistivity without saturation. Instead of considering about the mean free path, we demonstrate this universal bad metal behavior originate from the continuously decreasing height of low-frequency peak since its weight transfers to high energy region with temperature. Our study reveals the bosonic nature of the low-energy carriers and provides a strong support for the picture of tightly bound preformed pairs in describing the high-temperature superconductivity and other low-energy physics of the cuprates.

H71.00125: "Time-reversal symmetry breaking in topological superconductor Sr₀.₁Bi₂Se₃"  
P. NEHA, K. S. JAT (Presenter), School of Physical Sciences, Jawaharlal Nehru University (JNU), Delhi India, TANMOY DAS, Department of Physics, Indian Institute of Science Bangalore India, S. PATNAIK, School of Physical Sciences, Jawaharlal Nehru University (JNU), Delhi India — We report on the detection of the TRS breaking in the topological superconductor Sr₀.₁Bi₂Se₃, probed by zero-field μSR measurements. The TRS breaking provides strong evidence for the existence of a spin-triplet pairing state. The existence of TRS breaking is also verified by longitudinal-field μSR measurements, which negates the possibility of magnetic impurities as the source of TRS breaking. The temperature-dependent superfluid density deduced from transverse-field μSR measurements yields nodeless superconductivity with low superconducting carrier density and penetration depth λ = 1622(134) nm. From the microscopic theory of unconventional pairing, we find that such a fully gapped spin-triplet pairing channel is promoted by the complex interplay between the structural hexagonal warping and higher order Dresselhaus spinorbit-coupling terms. Based on Ginzburg-Landau analysis, we delineate the mixing of singlet- to triplet-pairing symmetry as the chemical potential is tuned far above from the Dirac cone. Our observation of such spontaneous TRS breaking chiral superconductivity on a helical surface state, protected by the TRS invariant bulk topology, can open avenues for interesting research and applications.
**H71.00126: Tight-binding Models for Two-dimensional Allotropes of Bismuth based on Wannier Functions**

QILE LI (Presenter), Materials Science and Engineering, Monash University, JACKSON SMITH, Physics, RMIT University, YUEFENG YIN, CHUTIAN WANG, Materials Science and Engineering, Monash University, MYKHAILO V. KLYMENKO, JARED H. COLE, Physics, RMIT University, NIKHIL MEDHEKAR, Materials Science and Engineering, Monash University — Recently two-dimensional allotropes of bismuth have attracted significant attention in the study of topological materials due to the strong correlation between their crystalline symmetry and electronic band topology.

This connection has been studied previously by directly transferring the empirical tight-binding models of semi-metallic bulk bismuth to its two-dimensional counterparts. However, this approach fails to describe the electronic structure of two-dimensional bismuth correctly. Therefore, new physical models are required when considering the two-dimensional forms of bismuth. In this study, we have constructed tight-binding models based on the Wannier representations derived from the Bloch states in first principles calculations. We have successfully reproduced the band features for three types of two-dimensional bismuth allotropes (Bi(111), Bi(110) and bismuthene) with minimal tight-binding parameters. We have verified the accuracy of the model by calculating band representations and topological invariants. We expect these simple but accurate tight-binding models can help to examine the electronic transport in these systems more effectively in the future.

*This work is supported by ARC Centre of Excellence in Future Low-Energy Electronics Technologies (CE170100039).*

**H71.00127: Probing black hole-like quasinormal modes in quantum Hall point contact geometries**

SURAJ HEGDE, Max Planck Institute for the Physics of Complex Systems, VARSHA SUBRAMANYAN (Presenter), BARRY BRADLYN, SMITHA VISHVESHWARA, Physics, University of Illinois at Urbana-Champaign — Recently it was shown by the authors that quantum Hall systems under the influence of an external saddle potential can realize the inverted harmonic oscillator (IHO), which is of importance in its own right and in the context of black hole physics [*]. A key feature of this potential is the occurrence of the resonant states/quasinormal modes (QNM) that decay in time via a finite outward flux. In this talk, we explore the directions for feasible experimental realisation and detection of these states. We analyze the bounded scattering potential of the Pöschl-Teller model whose scattering matrix has a resonant pole structure comparable to the IHO. We study quantities such as the non-escape probability that could be amenable to measurement and extraction of the decay rates of QNMs. We propose time-resolved measurements in quantum Hall point contact architectures for experimentally probing these wave packet scattering phenomena.

H71.00128: Probing the stability of Shastry Sutherland lattice in $\text{Er}_2\text{Pd}_2\text{Sn}$ and $\text{Er}_2\text{Pd}_2\text{In}$

GICELA SAUCEDO SALAS (Presenter), University of Texas, El Paso, SAHU BAIDYANATH, ANDRE MICHAEL STRYDOM, University of Johannesburg, STUART CALDER, Oak Ridge National Laboratory, HARIKRISHNAN S NAIR, University of Texas, El Paso — The group of 2:2:1 compound crystalizing in the $\text{Mo}_2\text{FeB}_2$ structure type, more commonly known as $R_2T_2X$ intermetallic ($R =$ rare earth, $T =$ transition metal, $X =$main group), have been reinvestigated recently owing to the spin liquid state in the underlying Shastry-Sutherland lattice (SSL) formed by the $R$ [1, 2]. Our motivation in investigating this compound is to explore the interplay of frustration and quantum criticality. For this study we have selected less-investigated $\text{Er}_2\text{Pd}_2\text{In}$ and $\text{Er}_2\text{Pd}_2\text{Sn}$. X-ray powder diffraction studies and subsequent Rietveld refinements confirmed that the compounds were phase-pure and crystallized in the tetragonal $\text{Mo}_2\text{FeB}_2$ structure. Both the compounds obeyed Curie-Weiss law in the paramagnetic regime, as judged from magnetic susceptibility data, which indicated anti-ferromagnetism. Specific heat data on both the compounds revealed a double peak indicating complex magnetic structure and phase transitions. We will present a detailed analysis of the magnetization and specific heat on both $\text{Er}_2\text{Pd}_2$(Sn/In). This motivated our current neutron diffraction experiment to determine the magnetic structure of these SSL compounds to probe for novel magnetic phases.

H71.00129: Thermoelectric transport in electronic systems at low and intermediate temperatures*

ZAHIDUL ISLAM JITU (Presenter), WOO-RAM LEE, Univ of Alabama - Tuscaloosa, ALEXANDER FINKELSTEIN, Texas A&M University, KAREN MICHAELI, The Weizmann Institute of Science, GEORG SCHWIETE, Univ of Alabama - Tuscaloosa — Measurements of thermoelectric transport in correlated electron systems probe different aspects of the many-body dynamics compared to electric and thermal transport. Here, we study theoretically how electron-electron interactions influence the Seebeck coefficient (thermopower) in disordered conductors when the phonon-drag is negligible. In particular, we discuss the regime of intermediate temperatures, where inelastic electron-electron collisions and elastic scattering on impurities occur at similar rates, and the low-temperature regime, where impurities provide the dominant scattering mechanism.

*This work is supported by DOE, ISF, NSF, and the College of Arts and Sciences at the University of Alabama.
H71.00130: Valence Transition in CeOs$_4$Sb$_{12}$ and Its T-H Phase Diagram*  PEI-CHUN HO
(Presenter), Physics, California State University, Fresno, JOHN SINGLETON, MARCELO JAIME, NHMFL, LANL, KATHRIN GOETZE, MATTHEW PEARCE, PAUL GODDARD, Physics, University of Warwick, KALYAN SASMAL, M BRIAN MAPLE, Physics, University of California, San Diego, TATSUYA YANAGISAWA, Physics, Hokkaido University — The filled skutterudite compound CeOs$_4$Sb$_{12}$ displays Kondo insulating behavior accompanied by a ~1 K Spin-Density-Wave order state. Recently it has also been suggested as a potential topological insulator. In penetration depth and magnetic susceptibility measurements, we found a Fermi-surface reconstruction in CeOs$_4$Sb$_{12}$ and an unusual phase boundary in the temperature $T$ vs magnetic field $H$ diagram associated with the valence transition from the Ce$^{4+}$ to Ce$^{3+}$ state, denoted as an L and an H phase, respectively. Based on the experimental features from magnetostriction, magnetoresistance, and high $T$ skin depth, a newly modified $T$-$H$ phase boundary of the L to H phases becoming much broader than what originally thought.\cite{1,2} The cyclotron mass of the conduction electron has a significant enhancement below ~35 T.

H71.00131: Kondo effect in a spin-orbit coupled quantum wire under the influence of an external magnetic field  EDSON VERNEK (Presenter), Physics and Astronomy, Ohio University, GEORGE B MARTINS, Physics, Federal University of Uberlândia, ROK ZITKO, Jozef Stefan Institute — We performed a detailed study of the Kondo effect occurring in a quantum dot coupled to a nanowire with Rashba and Dresselhaus spin-orbit couplings (SOC) subjected to an external magnetic field. We report the results for local static and dynamic physical properties of the dot in the Kondo regime obtained through the Numerical Renormalization Group method. Despite the SOC-induced magnetic anisotropy of the bands, the local quantum dot properties remain isotropic in the spin space at zero external field. However, when an external magnetic field is applied to the system, clear fingerprints of the SOC-induced anisotropy are revealed through the quantum dot physical properties that become dependant on the direction of the field. We demonstrate that the quantitative evaluation of this SOC-induced anisotropy, measured by tunneling spectroscopy techniques, can be used to determine the ratio of Rashba and Dresselhaus SOC strengths in the wire.
H71.00132: Effect of pseudospin-1 fermions on the RKKY interaction in α-T₃ lattice

GODFREY GUMBS (Presenter), Hunter college, ANDRII IUROV, Medgar Evers college, DANHONG HUANG, Air Force Research Lab — The interaction energy for the indirect-exchange or Ruderman-Kittel-Kasuya-Yosida (RKKY) interaction between magnetic spins localized on lattice sites of the α-T₃ model is calculated using linear response theory. In this model, the AB-honeycomb lattice structure is supplemented with C atoms at the centers of the hexagonal lattice. This introduces a parameter alpha for the ratio of the hopping integral from hub-to-rim and that around the rim of the hexagonal lattice. A valley and alpha-dependent retarded Green's function matrix in momentum-energy space is generated using the (A,B,C) lattice basis forming the low-energy Hamiltonian. The corresponding coordinate space Green's functions not only depend on which sublattice (A,B or C) the interacting spins are located but the cut-off wave vector used in the Fourier transform integral restricted to lie within the first Brillouin zone (B.Z.).

H71.00133: Plasmon dispersion in semimetallic pseudospin-1 α-T₃-based nanoribbons

ANDRII IUROV (Presenter), Medgar Evers College, PAULA FEKETE, West Point, US Military Academy, LIUBOV ZHEMCHUZHNA, DIPENDRA DAHAL, GODFREY GUMBS, Hunter college, DANHONG HUANG, Air Force Research Lab — We have calculated the electronic states, Coulomb potential energy, dynamical polarizability and the plasmon dispersion relations for both intrinsic and extrinsic semimetallic armchair graphene nanoribbons in α-T₃ materials. Our obtained results depend on both the parameter α, which is the ratio of the interaction strength and hopping coefficients between the hub and rim-atoms of the hexagonal lattice, and the number of atoms across the nanoribbon. The corresponding results for the dice lattice and graphene are also discussed as limiting cases of our work.

H71.00134: Suspended Nanowire Devices as Templates for Size-selected Nanocluster Networks*

PATRICK EDWARDS (Presenter), MARKO S. CHAVEZ, MOHAMED Y. EL-NAGGAR, VITALY V KRESIN, Physics, Univ of Southern California —

The study of metallic clusters at the nano-scale has revealed many finite-size effects not present in bulk materials, including electron shell structure, enhanced surface plasmon resonance, cluster-cluster charge tunneling, and Josephson current in potential superconducting arrays. Many of these features have been analyzed spectroscopically in the gas phase and via probe microscopy on surfaces, but an ongoing challenge is arranging size-selected nanoclusters into device geometries which would enable the exploration and optimization of transport phenomena based on their unique properties. We propose the use of suspended nanowire devices as scaffolds for organizing nanocluster assemblies. We will describe progress toward the fabrication and characterization of nanocluster chains supported by carbon nanotubes and by isolated bacterial flagella, both of which offer unique environments to study morphological and electronic properties of clusters on surfaces. Future work with such devices, employing varying nanocluster materials and tuned deposition conditions, will make it possible simultaneously to optimize the properties both of individual size-selected particles and of their nanoscale assemblies and networks.

*This work was supported by the NSF.
H71.00135: Resonant Scattering of Light from Dielectric Nanopillars AMINATOU DABOKEMP (Presenter), HUIZHONG XU, Department of Physics and Astronomy, San Francisco State Univ — The use of plasmonic nanoparticles dispersed in a visibly transparent polymer matrix has recently emerged as a promising alternative approach to realize transparent display [1]. The localized surface plasmon resonance of these particles allows them to selectively scatter light at certain wavelengths. However, their performance is limited due to the inherent absorption in these plasmonic particles. In this study, we use finite element method to study scattering of light from titanium dioxide nanopillars. Due to the large refractive index contrast between the nanopillar and its surrounding medium, strong resonant scattering can be achieved across the entire visible spectrum by varying its dimensions. As a result of zero absorption and sharp resonances, the figure of merit of these structures for transparent display applications is found to exceed values previously reported for plasmonic nanoparticles. Furthermore, the angular distribution of light scattered from these structures can be tuned by varying their dimensions. These nanopillar structures may be used to create novel metasurfaces with applications in metalenses, see-through head-up displays, and smart glasses.

H71.00136: Patterned Fabrication of Dielectric Nanopillar Arrays for Single Molecule Spectroscopy Applications* PATRICK DELEAR (Presenter), CHELSEA HOWARD, JOSEPH CHANDLER, BRIAN LE, OSKAR GARCIA, HUIZHONG XU, Department of Physics and Astronomy, San Francisco State Univ — The ability to guide and confine light on a scale much smaller than the wavelength of light opens up a variety of applications in fields including information processing, nanoscale imaging and lithography, and single molecule spectroscopy. For example, our previous studies have demonstrated the efficient guiding of visible light through 50-nm-diameter zinc oxide nanowire waveguides. However, the lengths of these zinc oxide nanowires are not well controlled due to the chemical synthesis method used, prohibiting their application in devices for single molecule spectroscopy. In this study, we use nanofabrication techniques to demonstrate the fabrication of titanium oxide nanopillars with controlled diameter and length. The use of these titanium oxide nanopillar waveguides for single molecule studies with fluorescence correlation spectroscopy at micromolar concentrations is probed and its application in studying the dynamics of protein molecules on cell membranes will be explored.

H71.00137: The magneto-optics in quantum wires comprised of vertically stacked quantum dots: A calling for the magnetoplasmon qubits  MANVIR KUSHWAHA (Presenter), Rice Univ — A deeper sense of advantages over the planar quantum dots and the foreseen applications in the single-electron devices and quantum computation have given vertically stacked quantum dots (VSQD) a width of interest. Here, we embark on the collective excitations in a quantum wire made-up of vertically stacked, self-assembled InAs/GaAs quantum dots in the presence of an applied magnetic field in the symmetric gauge. The gauge invariance is preserved. The Fermi energy is observed to oscillate as a function of the Bloch vector. Remarkably, the intersubband single-particle continuum splits into two with a collective excitation propagating within the gap. This is attributed to the (orbital) quantum number owing to the applied magnetic field. Strikingly, the alteration in the well- and barrier-widths can enable us to customize the excitation spectrum in the desired energy range. These findings demonstrate, for the very first time, the viability and importance of studying the VSQD subjected to an applied magnetic field\(^1\). The technological promise that emerges is the route to devices exploiting magnetoplasmon qubits as the potential option in designing quantum gates for the quantum communication networks.

H71.00138: One-phonon resonant Raman scattering in a nanowire in presence of an external electric field  MARICELA FERNÁNDEZ LOZADA (Presenter), Univ de Sonora, RICARDO BETANCOURT RIERA, RENÉ BETANCOURT RIERA, Fisica, Instituto Tecnológico de Hermosillo, RAÚL RIERA AROCHE, Univ de Sonora — In this work, the emission spectra for a one-phonon resonant Raman scattering process in a semiconductor nanowire of GaAs with a cylindrical symmetry in the presence of an external transversal and homogeneous electric field, as a mechanism for controlling the electron states and the selection rules due to confinement, are presented. The theoretical model considers single parabolic conduction and valence bands which are split into a sub-bands system due to confinement and electric field. We have considered Frölich type Hamiltonian for the electron-phonon interaction and only Stokes process, where the Comas-Trallero model for a free-standing wire has been used. Moreover, the electron intermediate states correspond to uncorrelated electron-hole pairs. As a result, the emission spectra corresponding to different laser energies and the selection rules for the process are discussed. The electric field produces the appearance of transitions linked to phonon oscillation modes where despite using dipole approximation in the electron-photon interaction.
H71.00139: Carrier dynamics in ultrathin gold nanowires: Role of Auger processes

GYAN PRAKASH (Presenter), Department of Physics, Indian Institute of Science, Bangalore, SUBHAJIT KUNDU, AHIN ROY, N RAVISHANKAR, ABHISHEK K SINGH, Materials Research Center, Indian Institute of Science, Bangalore, A K SOOD, Department of Physics, Indian Institute of Science, Bangalore — Carrier dynamics in metallic nanostructures is strongly influenced by their confining dimensions. Gold nanoparticles of size $\sim 2$ nm lie at the boundary separating metallic and non-metallic behavior. Here, we examine the carrier dynamics in high aspect ratio ultrathin gold nanowires (Au-UNWs) of average diameter $\sim 2$ nm using pump (3.1 eV) and coherent white-light continuum as a probe in the spectral range of 1.15 eV to 2.75 eV. We find that the transient carrier dynamics in Au-UNWs under extreme excitation regime is slower than predicted by the often used two-temperature model. Systematically probing the dynamics by varying the pump intensity from weak to strong excitation regime reveals that the mechanism of carrier relaxation through electron-phonon observed so far in larger size Au nanostructures is not sufficient in the Au-UNWs. We show that the reduced screening of e-e interaction due to spilling of conduction band and localization of core (d band) electrons at the surface promotes Auger heating.

H71.00140: Extending classical computational electrodynamics to quantum domain

CHRISTOPHER SILFIES (Presenter), JIANTAO KONG, Rutgers University, Camden — The Finite-Difference Time-Domain (FDTD) method [1] is widely used to simulate electromagnetic response of metallic structures, where abrupt boundary between materials is always assumed. However, when the scale is down to nanometer or even smaller, the non-abrupt electron density profile at metal surface causes problems, which are the so called nonlocal effects [2] (wavenumber-dependence) in plasmonics and nanophotonics research. We developed an approach [3] accounting for the non-abrupt surface profile, effectively extending the conventional FDTD method to nonlocal domain. This extension is still within the fast classical calculation scheme, but with the quantum mechanical surface plasmonic effects covered to first order. We utilized this approach to simulate on a few typical nanostructures, and the results on resonance shift and field enhancement agree very well with experiments and other ab initio calculations (e.g. DFT) in literature.

*This work has been supported by the new faculty start-up fund of Rutgers, the State University of New Jersey, Camden.
H71.00141: Cuboid Arrays as Surface Enhanced Raman Spectroscopy*  
ROSSHELL LAMUG (Presenter), AFTAB AHMED, California State University, Long Beach — Surface-enhanced Raman spectroscopy (SERS) allows for the enhancement of intrinsically weak Raman signal and thus enables the detection of analytes at single-molecule level and chemical specificity. Despite remarkable advancements in specificity and sensitivity however, SERS still suffers from a loss of signal that depends critically on techniques for nanofabrication. In this project, we use cuboid arrays as an ideal platform for a SERS substrate. This study investigates plasmonic materials and structural parameters of the array to achieve resonant enhancement of the local electric field. Our previous studies, using Finite Difference Time Domain method, revealed promising Raman enhancement factors, approaching $10^8$ using self-assembled arrays of gold nanocubes. These enhancement factors can be further improved with outside parameters such as hybridization of material and using a waveguide arrangement structure. The outcome of this work is the development of a low-cost user-friendly SERS substrate with high sensitivity, and stability. This work will broadly impact the field by assisting in the optimization of powerful multidisciplinary chemical sensing devices.

*This material is based upon work supported in part by the NIH Grant: CSULB MARC U*STAR; NIH Award No.: NIGMS T34 GM008074

H71.00142: Plasmon-induced efficient hot carrier generation in graphene on gold ultrathin film with periodic array of holes: Ultrafast pump-probe spectroscopy*  
GYAN PRAKASH (Presenter), RAJESH KUMAR SRIVASTAVA, SATYENDRA NATH GUPTA, A K SOOD, Department of Physics, Indian Institute of Science, Bangalore — Surface plasmon polaritons (SPPs) due to their inherent property of nanoscale confinement and localization, smaller than the interacting light wavelength, show strong light-matter interaction. Here, using ultrafast transient absorption spectroscopy we show that a high density of hot-electrons can be generated in graphene, through a strong interaction in a hybrid plasmonic structure of graphene with 3D gold hole array. Notably, pump-induced reflectivity shows significant signatures in the spectral window corresponding to extraordinary optical transmission resonances of gold hole array originating from the carrier dynamics in graphene. A comparative study of the graphene on gold film with and without hole array confirms the highly efficient direct plasmon-induced hot carrier generation in graphene.

H71.00143: Effect of temperature and defects on the mechanical and electronic properties of stacked van der Waals materials: The example of boron carbo-nitride  
SIBY THOMAS (Presenter), MOHSEN ASLE ZAEEM, Mechanical Engineering, Colorado School of Mines, Golden, CO-80401, USA — We demonstrate how the temperature and defects affect the electronic and mechanical properties in van der Waals bound low-dimensional systems, with the example of monolayer boron carbo-nitride (BCN). Molecular dynamics simulation reveals that as a hetero-structure of h-BN and graphene, the C-C bond in the BCN is responsible for an improved full width at half maximum (FWHM) compared to graphene, which ensures the structural integrity of the BCN monolayer. Besides, consistent with graphene and h-BN, the in-plane lattice parameter of BCN shows thermal contraction over a wide range of temperatures and exhibits a system size dependence. Further, the density functional theory calculations show that electronic bandgap varies substantially (between 0.73 and 1.2 eV) with the presence of Stone-Wales defects whereas it possess metallic character with the presence of vacancy defects. In addition, a tensile test analysis reveals that the elastic modulus and Poisson's ratio of monolayer BCN are anisotropic and decrease (increase) with the application of uniaxial tensile (compressive) strain which is beneficial for many technological applications.

H71.00144: Manipulating charge transfer from core to shell in CdSe/CdS/Au heterojunction quantum dots*  
EXIAN LIU (Presenter), KANISHKA P KOBBEKADUWA, PAN P ADHIKARI, Physics and Astronomy, Clemson University, OU CHEN, Department of Chemistry, Brown University, JIANBO GAO, Physics and Astronomy, Clemson University — Core/shell Quantum dots (QDs) or nanorods decorated with metal nanoparticles such as gold (Au) and platinum (Pt) have considerable applications in photocatalysis and optoelectronics. The shell medium plays a key role in tuning charge transfer and recombination process from core to metal domain. However, the study of influence of shell, which addresses the interplay between intrinsic excitons and shell-related surface states in trap-related core/shell/metal QD is currently lacking. In addition, the band offset between the core and shell that relies on temperature parameter also impacts the charge carrier transfer and recombination, but how do charge transfer and recombination vary with temperature still remains unclear.

Aim to comprehensively understand the interplay between charge transfer and recombination mechanisms in CdSe/CdS/Au heterojunction nanocrystals, we study these systems with temperature-dependent steady-state photoluminescence (PL) and time-resolved PL. We manipulate the charge transfer to shell surface by varying the tunneling barrier height resulted from temperature variation, and the barrier width resulted from shell thickness variation. These mechanisms are manifested by an intrinsic exciton emission and trap emission in the near-infrared range.

**H71.00145: Molecular migration in poly(vinyl alcohol) mixtures**

KATARZYNA MAJERCZAK

(Presenter), ZHENYU JASON ZHANG, Univ of Birmingham — Fluorescence techniques, both Fluorescence Recovery After Photobleaching and Fluorescence Correlation Spectroscopy were used to investigate the migration characteristics of small molecules in thin films composed of poly(vinyl alcohol) (PVA), glycerol and surfactants of various headgroup chemistry. We found that the diffusion kinetics of a molecular probe, Rhodamine B, is determined by both molecular arrangement within the film and the magnitude of charged intermolecular interactions. Addition of glycerol initially increases PVA chain flexibility, but inhibits probe movement once its concentration exceeds 44 wt% due to onset of noncompatibility between the two components. The presence of surfactants in the system was found to reduce the diffusivity of RhB in PVA matrix, which is consistent with that in bulk solutions. The reduced diffusion is likely due to steric inhibition for nonionic surfactants. However, the fine balance between inter-molecular interactions and steric inhibition governs the diffusivity of RhB when cationic or anionic surfactants are present in the matrix.

*This research was funded by School of Chemical Engineering, University of Birmingham, and EPSRC (grant number EP/P007864/1).

**H71.00146: Ab initio calculations on the depassivation reaction of H⁺ at a-SiO₂/Si(100) interfaces**

PEI LI (Presenter), Beijing Computational Science Res Ctr — Hydrogen is widely used to passivate the dangling bonds generated in the thermo xidation process, which significantly improves the electronic quality of the Si/SiO₂ interface. It may, however, make the devices vulnerable in certain environments. For example, ionization radiation may convert the excess hydrogen induced in the fabrication process to protons, and then the later may migrate to the interface and depassivate the dangling bonds saturated by hydrogen. In this study, the depassivation of \( P_{b1} \) and \( P_{b0} \) defects generated in amorphous SiO₂/Si(100) interfaces is investigated quantitatively. For \( P_{b1} \) defects, the proton detaches from the oxygen atom and then activates the defect. The forward reaction barrier is ~0.4 eV. After the reaction, the energy of the system decreases by 0.85 eV. The depassivation of \( P_{b0} \) defects is more unpredictable, because the proton may be trapped by other atoms or bonds during the long reaction path due to the location of the defect. In our simulation, the proton can be captured by Si-O-Si or Si-Si bond, and form threefold-coordinated O atom defect or Si-H⁺-Si bridge bond, respectively. The energy of the intermediate products is lower than the desired ones.
Perfect absorption in lossy anisotropic materials* SANJAY DEBNATH (Presenter), EVGENII NARIMANOV, Purdue Univ — Current state of art for perfect absorption is based on manipulating the incoming wave (which needs to be coherent) or the medium (needs to match impedance at optical frequency) or both. We show (Opt. Express. 27, 9561-9569 (2019)) perfect absorption of incoherent plane wave by planar semi-infinite slab based on the Brewster phenomenon. Lossless isotropic media support Brewster wave but cannot absorb energy. On the other hand, introducing loss in the medium causes Brewster wave to evolve directly into the leaky Zenneck surface wave. We demonstrate that anisotropic media with extra degrees of freedom in material parameters can bring the Zenneck wave back to Brewster wave even in the presence of loss. Our approach identifies potential classes of lossy anisotropic media who support this behavior and shows that the operating frequency of the proposed system is independent of physical dimensions. Our results show that many existing natural materials exhibit this effect at different frequencies from far-infrared to deep ultraviolet regimes.

Femtosecond laser-induced structural dynamics of Nickel (111) single crystal. An ultrafast time-resolved x-ray diffraction study. RUNZE LI (Presenter), PETER M. RENTZEPIS, Texas A&M University — Femtosecond, 8.04 KeV x-ray pulses, generated from a table-top system, are used to probe the lattice dynamics of 100 nm and 150 nm Ni (111) single crystals grown on sapphire substrates and irradiated with 800 nm, 100 fs laser pulses. At pump fluencies below the damage and melting threshold, we observed lattice contraction due to the formation of a blast force, and coherent acoustic phonons with a period of 35 ps and 46 ps for the 100 nm and 150 nm Ni (111) films, respectively. The spatiotemporal distribution of electron, spin, and lattice temperatures within the 150 nm thick nickel single crystal was also simulated using the three-temperature model. In addition to the ultrafast heating within the skin depth, this study also revealed the tens of picoseconds time required for heating the hundred nanometer bulk of the Ni (111) single crystal.
Magneto-Dielectric investigation in partially disordered Tb$_2$CoMnO$_6$ thin film

RAJESH MANDAL (Presenter), Physics, Indian Institute of Science Education and Research, Pune, MOHIT CHANDRA, MALVIKA TRIPATHI, R.J. CHAUDHARY, Indore Centre, UGC-DAE Consortium for Scientific Research, VASILY MOSHNYAGA, I. Physikalisches Institut, Georg-August-Universität Göttingen — Relaxor ferroelectrics are recognized as a family of disordered or partially ordered materials that are classified as a special class of dipolar glass with the formation of weakly interacting polarized nano domains (PNR) below a certain temperature. They are distinguished from normal ferroelectric materials in terms of broad transition in the temperature dependent dielectric constant and the dispersion of the transition temperature with applied frequency. Here we report the observation of magneto-dielectrically coupled ferroelectric relaxation at quite high temperature (200K) in Tb$_2$CoMnO$_6$/STO(100) double perovskite thin film. Partially B site disordered film has been grown by means of a metal-organic aerosol deposition (MAD) technique. This material is reported as ferromagnetic insulator with $T_C$ around 90K. Here we observe an enhanced transition temperature of 110K due to in plane strain. The deviation from the Curie-Weiss law far above $T_C$ indicates the development of short range spin correlation which is getting coupled with the electric dipoles present in the system.

A comparative study of characteristics of ZnO TFT for various substrate and fabrication parameters

SHAHIDUL ASIF (Presenter), Missouri State Univ — Several ZnO TFTs (thin-film field-effect transistors) are developed for assessing the characteristics as an FET under different fabrication parameters and substrate materials. These ZnO TFTs are grown using pulsed laser deposition in different substrate temperatures (300-700°C), in different oxygen pressures, and with or without annealing between 400-700°C. The substrates are n-type Silicon with SiO$_2$ insulating layer, and in some samples, they were accompanied by an additional HfO$_2$ film layer as a high dielectric material. All the TFTs have bottom-gate structure while the drain, source, and gates are equipped with gold electrodes fabricated by the sputtering method. The films are analyzed by XRD, Raman spectroscopy and photoluminescence as a verification of the presence of ZnO. Using an experimental set-up, the transfer and I-V characteristics are measured whereas the gate voltage is swept over a range of ~10-50 V. To assess the effectiveness of ZnO material for using in a TFT, the field-effect mobility, the drain current density, etc. are measured. Finally, the TFTs are tested for application in high frequency sweeping (1kHz-1MHz) as the hysteresis nature and power gain cut-off frequencies are compared.
H71.00151: Interface Orbital/Charge Reconstruction and Its Effect on Spin Orientation for (110)-La\textsubscript{2/3}Sr\textsubscript{1/3}MnO\textsubscript{3} Layer Sandwiched by LaCoO\textsubscript{3} Films*  FURONG HAN (Presenter), JIRONG SUN, Chinese Academy of Sciences, Institute of Physics — Here we made the first attempt to reveal the effect of orbital/charge reconstruction associated with interface engineering on spin degree of freedom. We took tensely strained (110)-LaCoO\textsubscript{3}/La\textsubscript{2/3}Sr\textsubscript{1/3}MnO\textsubscript{3}/LaCoO\textsubscript{3} trilayers as specimens, focusing on orbital reconstruction and accompanied effects. The most remarkable finding is the reordering of the energy levels of Mn-3d orbitals: the low-lying orbital becomes d\textsubscript{x2-y2} for sandwiched La\textsubscript{2/3}Sr\textsubscript{1/3}MnO\textsubscript{3} rather than d\textsubscript{3z2-r2} as expected for a bare La\textsubscript{2/3}Sr\textsubscript{1/3}MnO\textsubscript{3} film. Interlayer charge transfer via d\textsubscript{x2-y2} orbitals is further detected, which is the driving force for orbital reconstruction. Due to spin-orbit coupling, the charge/orbital reconstruction produces a chain effect on spin degree of freedom of the La\textsubscript{2/3}Sr\textsubscript{1/3}MnO\textsubscript{3} layer, resulting in a dramatic spin reorientation by 90° in film plane. The present work vividly demonstrates how to tune macroscopic properties of correlated oxides via the mutual coupling between different degrees of freedom.

H71.00152: Observation of high electron mobility with significant spin-orbit coupling in rock-salt YbO epitaxial thin film*  TAKU YAMAMOTO, KENICHI KAMINAGA (Presenter), DAICHI SAITO, DAICHI OKA, TOMOTERU FUKUMURA, Tohoku University — We report the optical and electrical properties of ytterbium monoxide (YbO) epitaxial thin films with unusual valence state of Yb\textsuperscript{2+} (4f\textsuperscript{14}5d\textsuperscript{0}) [1]. Consistent with the chemical trends of ytterbium monochalcogenides, YbO thin films exhibited the narrow bandgap of 0.25 eV and the large crystal field splitting of 5d orbitals. Electrical resistivity was tunable by electron doping to 5d conduction band via the introduction of oxygen vacancies. Also, electron mobility at 300 K increased up to 13 cm\textsuperscript{2}V\textsuperscript{-1}s\textsuperscript{-1} with increasing electron carrier density. The weak antilocalization at low temperature observed in the heavily electron-doped YbO suggests significant spin-orbit coupling owing to the heavy Yb nucleus. [1] T. Yamamoto et al., Appl. Phys. Lett. 114, 162104 (2019). Selected as Featured.

**H71.00153: InN/AlN/Si (111) semiconductor-insulator-semiconductor (SIS) heterostructure for ultrafast optical fibre communication (1550 nm)**  
ARUN CHOWDHURY (Presenter), ROHIT PANT, Materials Research Centre, Indian Institute of Science, BASANTA ROUL, Central Research Laboratory, Bharat Electronics, DEEPEndRA KUMAR SINGH, KARUNA KAR NANDA, SALURU BABA KRUPANIDHI, Materials Research Centre, Indian Institute of Science — In this work, we report on InN/AlN/Si (111) SIS-based self-powered, and ultrafast photodetector, which works at an extremely important wavelength of 1550 nm (fibre communication). InN was grown on AlN/Si template by plasma-assisted molecular beam epitaxy. The heterostructure with a top-bottom (vertical) type of electrode configuration shows a responsivity of 3.36 µA/W with transit times in milliseconds range at zero bias. The variation of photocurrent with respect to power density is nonlinear with an exponent of 1.36, which might be attributed to the presence of traps at the interfaces. To further elucidate the nature of interface of the SIS heterostructure, a low-temperature vertical electrical transport behaviour was studied over a range of 100 – 400 K. It reveals that the barrier height (BH) is inhomogeneous in nature at the hetero-interface. It has been explained by assuming the presence of double Gaussian distribution of BH at the SIS interface based on thermionic emission theory. The double Gaussian distribution of the BH indicated the presence of traps at the interface which was already speculated from the photocurrent and power density relation of the photodetection studies.

**H71.00154: Graphene Doping in LiMnO$_4$ cathode of Lithium Ion Battery**  
NNAMDI ENE (Presenter), ERICA S WILEY, MEHMET ALPER SAHINER, Physics, Seton Hall University — Lithium ion batteries, due to their high-power density and high energy are being utilized more and more in present day electronic devices. One way we might improve the absorbance of these batteries is by reducing the band gap energy of the materials used as either the anode or the cathode. Graphene, having a crystalline, 2-dimensional and monoatomic structure has a high electrical conductivity. Graphene is also called a zero-band gap semiconductor. Previous research supports the reduction in the band gap energy by the introduction of graphene as a dopant in thin films. (Elmas et al. 28) This research will thus seek to study the effects of graphene doping in the LiMnO$_4$ cathode region, to electronic energy configuration and the electrical performance of lithium ion thin films prepared by pulsed laser deposition.

H71.00155: Self-powered, broadband and ultrafast MoS$_2$/AlN/Si based photodetector*

DEEPEndra Singh (Presenter), Rohit Pant, Basanta RouL, Arun Chowdhury, Karuna Kar Nanda, Saluru Baba Krupanidhi, Indian Institute of Science — Heterostructures of ultrathin 2D layered materials and wide band gap semiconductors offer possibilities of high-performance electronic devices. The absence of a band gap in graphene, which limits its application as a switch, MoS$_2$ has attracted considerable attention in recent years due to its excellent optoelectronic properties, as well as the presence of a narrow band gap. Here, we have reported a self-powered, broadband and ultrafast photodetector based on MoS$_2$/AlN/Si heterostructure. MoS$_2$ thin film has been deposited on AlN template on n-Si(111) by pulsed laser deposition. The vertical transport of the heterostructure exhibits excellent photodetection properties at zero bias condition. The device shows a broadband photoresponse in the range of 300-1100 nm, with a maximum responsivity of 5.47 A/W at 900 nm. Transient analysis of the device at 900 nm shows an ultrafast detection, with rise/fall times of 12.5/14.9 μs. Band alignment studies of MoS$_2$ and AlN has been done by XPS and a band diagram of the heterostructure depicting the self-powered transport has been proposed.

H71.00156: Understanding the negative compressibility in a 2D electron gas: Application to LaAlO$_3$/SrTiO$_3$*

Aditi D Mahabir (Presenter), Univ of North Florida, Alexander Balatsky, Nordic Institute for Theoretical Physics, Jason Haraldsen, Univ of North Florida — We investigate the effects of a two-band coupling on the negative compressibility for the two-dimensional electron gas. Using a homogeneous 2D electron model and a two-band description of the electron interactions, we examine the dependence of critical carrier density, dielectric constant, and effective mass on the negative compressibility of the 2D electron gas and compare results to the at the complex oxide interface of LaAlO$_3$/SrTiO$_3$. From our calculations, we show that the presence of interband coupling will produce a dramatic decrease in the polarizability and the critical carrier density of the 2DEG. Furthermore, we find that the ratio of the effective masses of the bands has a distinct and dramatic effect on the negative compressibility.

*This project is supported, in part, by the Institute for Materials Science at Los Alamos National Laboratory.
H71.00157: Epitaxial growth and interface band alignment studies of all oxide α-Cr$_2$O$_3$/β-Ga$_2$O$_3$ p-n heterojunction* SAHADEB GHOSH (Presenter), MADHUSMITA BARAL, Synchrotrons Utilization Section, Raja Ramanna Centre for Advanced Technology, Indore and HBNI, Mumbai, RAJIV KAMPARATH, Raja Ramanna Centre for Advanced Technology, R. J CHOWDHURY, SQUID-VSM and PLD Lab, UGC-DAE Consortium For Scientific Research, Indore, D. M PHASE, SEM and Beamline Lab, UGC-DAE Consortium For Scientific Research, Indore, S. D SINGH, TAPAS GANGULI, Synchrotrons Utilization Section, Raja Ramanna Centre for Advanced Technology, Indore and HBNI, Mumbai — Epitaxial growth of α-Cr$_2$O$_3$(p-type) on c-Al2O3 and β-Ga$_2$O$_3$ (n-type) on α-Cr$_2$O$_3$(p-type) has been carried out to make an all oxide epitaxial n-type β-Ga$_2$O$_3$/p-type α-Cr$_2$O$_3$ heterojunction using RF sputtering. A valence band offset of 3.38 ± 0.2 eV at the heterojunction is determined using Kraut's method. From the bandgap measurements of α-Cr$_2$O$_3$ and β-Ga$_2$O$_3$, the conduction band offset of 1.68 ± 0.2 eV at the heterojunction is obtained. Thus, the band alignment at this heterojunction is found to be staggered (Type-II), which leads to the confinement of electrons and holes in the β-Ga$_2$O$_3$ layer and α-Cr$_2$O$_3$ layer, respectively. Our results provide a pathway to design all oxide optoelectronic devices based on a p-n heterojunction consisting of n-type β-Ga$_2$O$_3$ and p-type α-Cr$_2$O$_3$.

*The authors are thankful to HBNI, RRCAT for financial support during the course of the work.

H71.00158: Quantum Correction to the Work Functions of Clean Tungsten Surfaces under Electric Fields LIANGLIANG XU (Presenter), YUE WANG, MING-CHIEH LIN, Department of Electrical and Biomedical Engineering, Hanyang University, TSAN-CHUEN LEUNG, Department of Physics, National Chung Cheng University, HUA-YI HSU, Department of Mechanical Engineering, National Taipei University of Technology — Tungsten has a relatively high work function, electron emission is largely limited. In this work, first-principles calculations are used to study the work functions of tungsten (100), (110), and (111) surfaces under different electric fields. We have carefully and systematically tested the convergence of density-functional-theory (DFT) calculations in the local-density approximation (LDA) and generalized-gradient approximation (GGA) with a plane-wave basis set with the projector-augmented wave (PAW) method as implemented in the Vienna ab initio simulation package (VASP). Detailed study of field emission by using VASP is performed and it is found when we increase the electric field strength, the work functions of tungsten surfaces are reduced accordingly. A new scaling law of work function reduction due to the charge transfer near the metal/vacuum interface caused by external electric field is obtained. The quantum effect is different from the classical Schottky effect of lowering work function due to an external electric field. With the quantum correction, the predictions of Richardson-Dushman and Fowler-Nordheim equations under strong electric fields for thermionic and field emissions, respectively can be improved.
**H71.00159: Picosecond laser ultrasonic measurements of elastic properties of transition metal dichalcogenides**

ETHAN MURRAY, MADELAINE PELLETIER, JACOB STULIGROSS, ELLIS THOMPSON, BRIAN DALY (Presenter), Vassar College, SENG HUAT LEE, Pennsylvania State University — We report ultrafast optical pump-probe measurements of sound velocity and attenuation for GHz frequency longitudinal acoustic strain pulses in MoSe$_2$ and WSe$_2$. High-quality bulk single crystals of 2H-MoSe$_2$ and WSe$_2$ were synthesized by chemical vapor transport with iodine as the transport agent. Thin layers with thicknesses ranging from a few nm up to a few hundred nm were then mechanically exfoliated onto sapphire or SiO$_2$/Si wafers. A degenerate optical pump-probe experiment was performed with a Ti: sapphire ultrafast laser with peak wavelength varied from 760 nm to 830 nm. At these wavelengths, the optical absorption in these crystals is strong enough that a high frequency acoustic strain pulse with frequency components approaching 100 GHz is generated. This picosecond ultrasonic pulse travels back and forth in the exfoliated layer and causes a reflectivity change that is measured by time-delayed probe pulses via the strong strain dependence of the optical properties. Longitudinal sound velocities as well as an upper bound on attenuation of 100 GHz phonons are determined by comparing reflectivity data to 1D simulations.

**H71.00160: Ab-initio study of surface plasmons on palladium surfaces**

UNAI MUNIAIN (Presenter), DIPC, RUBEN ESTEBAN, DIPC and Ikerbasque, VYACHESLAV SILKIN, DIPC, Ikerbasque and UPV/EHU — Collective electronic excitations at metal surfaces lead to strongly localized electromagnetic fields that play a key role in numerous phenomena in physics, material science, biology or medicine [1]. In particular, surface plasmons are modes that appear in vacuum/metal boundaries, with a constant dispersion relation in the long-wavelength limit predicted by simple models [2]. However, in real metallic systems such predictions often fail. In particular, in many materials, when the non-local behavior of the electronic response is considered, additional collective modes characterized by significantly lower frequencies may appear [3]. In this work, we perform first-principles time-dependent density-functional calculations of the excitation spectra of the palladium surfaces, in order to establish the characteristics of its surface plasmons. We analyze the properties of the surface collective excitations using the surface response function, which is closely related to the permittivity of the material. Our results thus contribute to gaining a better understanding of the optical response of palladium structures.

*GV Project PI2017-30*
**H71.00161: Comparing Magnetron Sputtered ScN Films Grown on Sapphire ((10-10) and (1-102)) Substrates**

TOBIN MURATORE (Presenter), SAID ELHAMRI, Physics, University of Dayton, AMBER REED, JOHN CETNAR, Air Force Research Laboratory, DAVID C LOOK, Wright State University, KURT EYINK, HADLEY SMITH, ZACHARY BIEGLER, Air Force Research Laboratory — ScN films with high quality crystal structure and desirable carrier concentration have previously been grown on sapphire (0001) substrates. This study seeks to determine whether similarly high quality films can be grown on (101-0) and (1-102) orientated sapphire. The depositions for this study were carried out via reactive, unbalanced, DC magnetron sputtering. Previous growth of ScN on sapphire (0001) showed film quality is sensitive to sputtering conditions. This study seeks to determine what, if any, sputtering conditions can produce films of comparable quality to those grown on sapphire (0001) substrates on the lower symmetry surfaces. The impact of these growth conditions on the crystal quality and electrical properties were evaluated using x-ray diffraction and Hall-effect measurements. X-ray diffraction results indicate that growth on sapphire (1-102) is sensitive to temperature, with optimal growth occurring in a 40°C window. For (10-10) sapphire, similar crystal quality occurs over temperatures from 500-900°C. XRD also shows no conditions tested for either substrate displayed the single crystal growth present on (0001) sapphire.

*This research was supported the Air Force Office of Scientific Research through project FA9550-RYCOR490

**H71.00162: WITHDRAWN ABSTRACT** —

**H71.00163: Compression-rate dependent domain growth patterns in diacetylenic chiral lipids Langmuir films: choline vs. ethanolamine head-groups**

PRITAM MANDAL (Presenter), Durgapur Women's College — In this talk, we discuss domain growth in Langmuir monolayers of two diacetylenic lipids, one with choline and other with ethanolamine head group. We found that (i) Unlike a diacetylenic lipid, Diyne PE (23:2), the diacetylenic Diyne PC (23:2), does not form chiral hierarchal self-assembled patterns. (ii) Structured solid domains in Diyne PC (23:2) Langmuir layer forms within a lower temperature range than with Diyne PE (23:2). Comparing their domain morphology we argue that choline and ethanolamine head groups interact differently with water, influencing the packing-mode. (iii) For both lipids, the growth patterns depend on the compression speed. At lower compression-rate the condensed domains grow as fractal dendrites with straight backbone whereas at rapid compression rate, domains grow as curved claws developing branches as they grow. Since slow or rapid compression rate pushes the monolayer to different non-equilibrium state (different super-saturation), we reason that solid phase grow out of different metastable states, generating distinct morphology.

*I acknowledge the King Abdullah University of Science and Technology (KAUST), Thuwal-6900, KSA, where I first started this study as a postdoc.*
**H71.00164: Ultrasonic modification of hydrophobin bubbles and droplets for multiphase systems***  
ZHAOXIAN ZHANG (Presenter), PAUL RUSSO, SAAD BHAMLA, SAMYAK JAIN, UDITA RINGANIA, Georgia Inst of Tech — Cerato Ulmin(CU), a fungal protein classified as Hydrophobin, is an amphipathic surfactant which self-assembles at interfaces. CU can encapsulate air or oil in aqueous solutions to form non-spherical bubbles or droplets, similar to those formed by interfacial composite materials with solid-like surfaces. A sufficient dispersion of CU in water can create concentrated oil droplet/air bubble structures resembling complex multi-phase systems. These structures, which are observed to be stable for days, could have a variety of applications in emulsion engineering, reaction catalysis, and constructing multi-scale metastructures, among many others. Ultrasonic agitation was used to modify these structures, and it was discovered that the frequency of the ultrasound corresponded to the length scale of air-filled structures, by mechanism of Minnaert Resonance. With this method it was possible to select the size distribution of the air-filled structures. Oil-filled structures behaved differently, yet with sufficient ultrasound amplitude, it was possible to produce CU-oil nano-emulsions, likely by the mechanism of cavitation. The size and longevity of these nano-emulsions were studied by dynamic light scattering.

*Funding from Solvay through the MSE Research Scholars Program.

**H71.00165: Scanning Probe Microscopy of Two Dimensional Covalent Organic Frameworks***  
HARSHAVARDHAN MURALI (Presenter), ZACHERY ENDERSON, CAMERON FERIANTE, RAGHUNATH DASARI, HONG LI, SIMIL THOMAS, TIMOTHY C PARKER, JEAN-LUC E BREDAS, SETH R. MARDER, PHILLIP N FIRST, Georgia Inst of Tech — Covalent organic frameworks (COFs) are a new class of materials that can be designed to exhibit interesting physical, chemical and electronic properties. In this work, we study the growth and properties of single layer covalent organic frameworks that we synthesize on noble metal surfaces, typically via an Ullmann-like process accomplished through thermal deposition and annealing. An outstanding challenge in 2D-COF on-surface synthesis is to achieve long range, defect free crystalline order over hundreds of nanometers. Using scanning tunneling microscopy (STM), we probe COF growth and island formation under different preparation conditions, from monomer self-assembly to covalent bond formation. We also study the electronic properties of COF islands obtained in this process, including effects of finite size and substrate interaction, using scanning tunneling spectroscopy and comparisons to theoretical first-principles calculations.

*This work is funded by the United States Army Research Office under grant number W911NF-15-1-0447 (MURI).*
**H71.00166: Nanotribology of Phosphonium Phosphate Ionic Liquid: a Combined Atomic Force Microscopy and Surface Spectroscopy Study**  
FILIPPO MANGOLINI, ZIXUAN LI (Presenter), OSCAR MORALES-COLLAZO, University of Texas at Austin, JERZY T. SADOWSKI, Brookhaven National Laboratory, HUGO CELIO, ANDREI DOLOCAN, JOAN BRENNECKE, University of Texas at Austin — Ionic liquids (ILs) have recently gained considerable attention owing to their unique and tunable properties (e.g., wide electrochemical window, high thermal stability), which make them potentially useful for a range of applications, including batteries, fuel cells, catalysis, and lubrication. When IL are used as lubricants, the interface between the IL and the solid surface plays a pivotal role to determine the friction/wear response. Despite the weight of the studies published in the literature, remarkably little is still known about the structure of solid/IL interfaces and its relationship with the lubrication mechanism/performance of ILs. Here, we used atomic force microscopy (AFM) to visualize and quantify the processes occurring at sliding interfaces in situ, in single-asperity nanocontacts. The AFM experiments, in which a diamond tip was slid on steel in phosphonium phosphate ILs, indicated a significant friction reduction only after the removal of the native surface oxide from steel. Based on laterally-resolved ex situ analyses of the surface chemistry of steel by X-ray photoemission and low energy electron microscopy, and time-of-flight secondary ion mass spectrometry, a simple phenomenological model will be proposed to account for the observed lubrication behavior.

**H71.00167: WITHDRAWN ABSTRACT**

**H71.00168: Planar polymers under cylindrical confinement**  
DULCE VALENCIA (Presenter), Northwestern University — We show that the cylindrical confinement of a planar ribbon gives rise to the formation of stationary helical shapes, previously observed in molecular dynamics simulation studies of some planar polymers inside nanotubes. In the limit of small twisting deformations, we notice that a confined ribbon describes identical equilibrium configurations of an elastic rod on the plane. Also, every locally planar strip adsorbed on a cylinder is forced to follow a helical envelope, as its length increases. We also determine the forces and torques that sustain each ribbon equilibrium configuration through the equilibrium geometry and the confinement surface parameters.

*Northwestern University*
H71.00169: SAMPLE: Surface structure search enabled by coarse graining and statistical learning  LUKAS HÖRMANN (Presenter), ANDREAS JEINDL, ALEXANDER T. EGGER, MICHAEL SCERBELA, OLIVER T. HOFMANN, Institute of Solid State Physics, Graz University of Technology — Studying the electronic structure of organic monolayers on inorganic substrates requires knowledge about their atomistic structure. Such monolayers often display rich polymorphism arising from diverse molecular arrangements in different unit cells. The large number of possible arrangements poses a considerable challenge for determining the different polymorphs from first principles.

To meet this challenge, we developed SAMPLE[1-3], which employs coarse-grained modeling and machine learning to efficiently map the minima of the potential energy surface of commensurate organic adlayers. Requiring only a few hundred DFT calculations of possible polymorphs as input, we use Bayesian linear regression to determine the parameters of a physically motivated energy model. These parameters yield meaningful physical insight and allow predicting adsorption energies for millions of possible polymorphs with high accuracy.

We demonstrate SAMPLEs capabilities on the systems of naphthalene[1] and TCNE[2,3] on coinage metals where we predict the energetically most favorable polymorphs and compare them to experimental data.

H71.00170: Effects of Ligand Composition on Protein Corona Formation around, and the Surface Structure of, Au Nanoparticles  SAM HOFF (Presenter), University of Colorado, Boulder, DESIRÉ DI SILVIO, SERGIO MOYA, Soft Matter Nanotechnology Lab, CIC biomaGUNE, RONALD ZIOLO, Centro de Investigación en Química Aplicada, HENDRIK HEINZ, University of Colorado, Boulder — Coatings on nanoparticles in biological environments greatly impact the dynamics and stability of the nanoparticles. Destinations, and potential function of nanoparticles can be changed by attaching ligands to the nanoparticle surface. In this study, molecular dynamics is used to study how different ligands, and specifically different chemical end groups, alter the surface structure and dynamics of the ligands in solution. PEG2000, Alkyl-PEG600-Glucosamide, and Alkyl-PEG600-Butanamide and their specific interactions with Bovine Serum Albumin and Concanavalin A are studied in detail. The effects of altering the end group on Alkyl-PEG600-Butanamide to Propanamide and Ethanamide are explored, and is found to have a significant impact on the surface structure at the ligand-water interface, potentially altering nanoparticle interactions in solution, as well as protein corona formation. The CHARMM36-Interface force field is used throughout all simulations which yields interfacial properties directly comparable to experimental measurements. The study is expected to lead to new insight into how protein-ligand interactions work, as well as advancing understanding of how ligand conformations can affect their environmental interactions.
H71.00171: Selective studies of adsorption of Ag\textsubscript{8}M and Ag\textsubscript{14}M clusters (M = Au, Co and Pt) on alumina substrate*  ISABELLA LEVENSOHN KASTOR (Presenter), NUSAIBA ZAMAN, ABDELKADER KARA, Univ of Central Florida — Small silver clusters were used as catalyst for Li-air batteries, which controlled the rate of discharge at the cathode. The gap near the fermi energy was shown to control the oxygen reduction, an important reaction for LiO\textsubscript{2} formation. One can vary the size of the cluster to vary the gap, however, this “knob” provides limited variance. Hence, we study the effect of alloying in combination with size variation of Ag\textsubscript{8}M and Ag\textsubscript{14}M clusters (M = Au, Co and Pt). Using Density Functional Theory (DFT), we determine the most stable geometry of these bimetallic clusters and calculate the binding energies of these clusters on the alumina substrate. We explore how the gap at the Fermi level of the system varies as a function of elemental composition and size of the cluster. Bader charge analysis is also performed to probe how the charges are transferred between the cluster and the substrate. These preliminary studies will open the door for more systematic studies of alloy clusters of different size and stoichiometry for Li-O\textsubscript{2} battery cathode design as well as for general catalysis.

H71.00172: Structural and magnetic transition in NiO(111) surface  WANDONG XING (Presenter), YANG ZHANG, Tsinghua University, FANYAN MENG, University of Science and Technology Beijing, JING ZHU, RONG YU, Tsinghua University — We report an experimental and theoretical analysis of the NiO(111) surfaces combining aberration corrected TEM and first-principles calculations. An unreconstructed O-terminated (1×1) surface and a reconstructed O-terminated surface (with the topmost Ni in tetrahedral sites, a wurtzite-like surface stacking) have been revealed. Here, the two surfaces are shown to be stabilized by charge compensation, arising from changing the valence state of the topmost Ni\textsuperscript{2+} into Ni\textsuperscript{3+} ions and providing the additional positive charges to the surface. In addition, it is found that the main difference between the two surface structures is the movement of the topmost Ni atoms from octahedral position to tetrahedral position, coupling to a spin transition from the low-spin state (Ni\textsuperscript{3+}-LS) to the high-spin state (Ni\textsuperscript{3+}-HS).
H71.00173: Using Machine Learning to Understand Mechanical Loss in LIGO Mirror Coatings
SAGADA PENANO (Presenter), KIRAN PRASAI, E.L. Ginztion Laboratory, Stanford University, JUN JIANG, ALEC MISHKIN, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida, RICCARDO BASSIRI, MARTIN M. FEJER, E.L. Ginztion Laboratory, Stanford University
— The sensitivity of future generations of gravitational wave detectors such as LIGO will be limited by thermal noise from the mirror coatings on the test masses. A major source of thermal noise is the mechanical loss of the coatings. The mechanical loss at temperatures higher than 10 K is believed to be the result of thermally activated transition between two level systems (TLSs) in the amorphous coating. By using a multilayer perceptron neural network to understand the atomic structures of many computer-generated two-level systems (TLS) of amorphous tantala (a-Ta$_2$O$_5$), a prospective coating material, we aim to identify the structural motifs that contribute to mechanical loss. From an analysis of many independent TLSs, we can identify which atoms are most likely to relax by comparing changes in atomic energies and positions. Values that describe the structural features of these atoms can then be computed using angular and radial distribution functions. Using these predictions, a common pattern of relationship between structure and relaxation behavior can be extracted. The results will likely aid in understanding what gives rise to the measured values of mechanical loss and will help determine the best materials and deposition parameters for lower mechanical loss mirror coatings.

H71.00174: Invalidity of the BCS theory of superconductivity
JORGE HIRSCH (Presenter), University of California, San Diego — A theory that purports to describe the natural world can be proven invalid by either (a) an experimental result or (b) a theoretical proof that it is internally inconsistent. However BCS is special: it cannot be disproved by (a) because any superconductor yielding an experimental result that doesn't conform to BCS is simply declared to be 'unconventional'. Hence we are left with (b). In a process where the temperature of a type I superconductor in a magnetic field changes, the London penetration depth and hence the magnetic flux changes, generating a Faraday electric field. BCS theory predicts that the electric field gives rise to a normal current and as a consequence Joule heat is dissipated, in an amount that depends on the speed of the process, and it also predicts that the final state is independent of the speed of the process. I show that these two predictions cannot be simultaneously reconciled with the laws of thermodynamics. Therefore, BCS theory is internally inconsistent. I propose a resolution of this conundrum through physics that is not part of BCS theory.

H71.00175: WITHDRAWN ABSTRACT —
H71.00176: Numerical solution of the full-bandwidth Eliashberg equations including vertex corrections beyond Migdal's approximation  ALEX APERIS (Presenter), FABIAN SCHRODI, PETER OPPENEER, Uppsala University — We solve the full bandwidth and non-adiabatic Eliashberg equations for electron-phonon mediated superconductivity by fully including the first vertex correction in the electronic self-energy. The non-adiabatic equations are solved numerically without further approximations for a generic one band model system. We compare the results with outcomes of adiabatic Eliashberg calculations. Non-adiabatic contributions can increase, decrease or have negligible effect to the superconducting gap depending on the dimensionality of our system, the degree of non-adiabaticity and the coupling strength. We further examine effects on the transition temperature and the electron-phonon coupling constant. Our treatment opens up the possibility of systematically studying vertex correction effects in strongly coupled and/or adiabatic superconductors, such as the ones with high transition temperature.

H71.00177: Melting transition of the nematic state in an under-doped d-wave superconductor*  HONG-YI CHEN (Presenter), YU-YO CHEN, National Taiwan Normal Univ — We study the melting transition of smectic state in an under-doped d-wave superconductivity. We demonstrate that the transition is discontinuous to the nematic state by increasing the impurities. We calculate the entropy as a function of impurities which shows a sharp transition between the smectic and nematic states. We also show that the density-of-states at the Fermi energy emerges as the sub-gap induced by the SDW order is smeared out gradually. The transition between the smectic and nematic states is associated the reconstruction of the electronic Fermi surface. We calculate the superfluid density that exhibit a plateau and indicates that the nematic state development in d-wave superconductor is distinct from high-temperature pseudogap.

H71.00178: Finding the static critical exponent in YBa2Cu3O7 using critical current density  IOAN DASCALU (Presenter), MATTHEW C. SULLIVAN, Ithaca Coll — We grew thin films of hole-doped cuprate YBa2Cu3O7 (YBCO) using optimized pulsed laser deposition and patterned them into a meander wire with conventional photolithography techniques. We examined the normal-superconducting phase transition of the thin films via a critical scaling analysis of voltage vs current isotherms, where each measurement is the average of many reverse-polarity measurements. We expect the superconducting phase transition to obey critical (3D-XY) theory near the critical temperature and obey mean-field theory further from the critical temperature. We show that critical current density can access both the critical regime and the mean-field regime in a single sample. We present our results on the static critical exponent in both regimes for YBCO.
**H71.00179: Transport characteristics of type II Weyl semimetal MoTe\(_2\) thin films grown by chemical vapor deposition**

NIRAJ BHATTARAI (Presenter), ANDERW W FORBES, Physics, The Catholic University of America, RAJENDRA DULAL, Advanced Physics Laboratory, Institute for Quantum Studies, Chapman University, IAN L PEGG, JOHN PHILIP, Physics, The Catholic University of America — Theoretical calculations and experimental observations show MoTe\(_2\) is a type II Weyl semimetal, along with many members of transition metal chalcogenides family. We have grown highly crystalline large-area (upto 8mm X 4mm) MoTe\(_2\) thin films on Si/SiO\(_2\) substrates by chemical vapor deposition. Very uniform, continuous, and smooth 1T'-MoTe\(_2\) films were obtained as confirmed by scanning electron microscopy, atomic force microscopy, x-ray and Raman spectroscopy analyses. Measurements of the temperature dependence of longitudinal resistivity and current-voltage characteristic at different temperature are discussed. Unsaturated, positive quadratic magnetoresistance of the as-grown thin films has been observed at various temperatures below room temperature. Hall resistivity measurements confirm the majority charge carriers are holes. Using the single band model, carrier concentration was calculated to be \(2.38 \times 10^{21}\) holes cm\(^{-3}\) at 10 K, which is semimetallic, and increasing with temperature. These results will guide us in the way of pragmatic applications of thin films MoTe\(_2\) in future electronic devices.

**H71.00180: WITHDRAWN ABSTRACT**

**H71.00181: "Thickness dependent characteristics of Single Crystalline Bi:YIG Thin Film grown with different orientation"**

GANESH GURJAR (Presenter), School Of Physical Sciences, Jawaharlal Nehru University New Delhi India, VINAY SHARMA, Special Centre for Nanosciences, Jawaharlal Nehru University New Delhi India, SATYABRATA PATNAIK, School Of Physical Sciences, Jawaharlal Nehru University New Delhi India, BIJOY KUANR, Special Centre for Nanosciences, Jawaharlal Nehru University New Delhi India — The Magneto-Optical (MO) properties are increases when bismuth (Bi) is substituted in the YIG (Bi\(_{0.1}\)Y\(_{2.9}\)Fe\(_5\)O\(_{12}\), BYIG). BYIG films of two different thickness were grown with different orientation ([111] and [100]) by pulsed laser deposition (PLD) technique over single crystalline Gadolinium gallium garnet (GGG) substrates. The BYIG grown with [100] orientation was observed structurally better with lesser strain (around 40% lesser). As the thickness of film decreases, the size of lattice parameter is also slightly decreases and it is more (by 0.073%) for the film grown over GGG having [111] plane. Larger ferromagnetic resonance (FMR) line width is observed in [111] directed film (100 Oe) as compared to [100] directed film (60 Oe) and also it decreases with the film thickness (100 Oe to 47 Oe in [111] and 60 Oe to 39 Oe in [100] directed film). The value of net effective magnetization and Gilbert damping constant is observed to be increases with decrease in thickness of the film. The low Gilbert damping constant (1.53\(\times\)10\(^{-4}\), [100]) is observed as compared with (2.68\(\times\)10\(^{-4}\), [111]). Thus BYIG thin film grown on GGG along [100] direction shows better structural and magnetization characteristics and hence can be used for microwave devices such as microwave filter etc.
**H71.00182: Study of V/TiO$_2$ interface by X-ray Photoelectron Spectroscopy**

MIRANDA S MARTINEZ (Presenter), ANIL CHOURASIA, Texas A&M University, Commerce — The V/TiO$_2$ interface has been studied by the technique of x-ray photoelectron spectroscopy (XPS). Thin films of titanium were deposited on a quartz substrate and oxidized in situ to form TiO$_2$ overlayer. Thin films of vanadium were then deposited onto this TiO$_2$ substrate. The samples were annealed at 100, 200, 300, 400, and 500°C for fifteen minutes and were analyzed in situ by XPS. The titanium 2p, the vanadium 2p and the oxygen 1s core level analyzed for this purpose. The aluminum x-rays (energy = 1486.6 eV) were used as the source of excitation. The spectral data have been recorded at 45 degree take-off angle. The spectral data have been analyzed to estimate the chemical reactivity at the V/TiO$_2$ interface. The spectral features (shift in the core levels and the shape of the core level peaks) have been utilized. The chemical reactivity as a function of the thickness of the vanadium overlayer and the annealing temperature has been established and will be presented.

**H71.00183: Au$_n$ cluster deposited on a TiO$_2$ (110) slab**

PABLO DE LA MORA (Presenter), Facultad de Ciencias, Universidad Nacional Autonoma de Mexico, GUSTAVO TAVIZON, Facultad de Quimica, Universidad Nacional Autonoma de Mexico, ESTHER AGACINO, FES Cuautitlan, Universidad Nacional Autonoma de Mexico — The unreactiveness of gold breaks down in the nanoscale, where it has a very strong catalytic activity. To study this, Au atoms are added in the 110 surface of the rutile, TiO$_2$. In this study gold atoms are added one by one to the surface and different configurations are energetically optimized. The objective is to study how the atoms interact with the rutile surface and when the 2D to the 3D transition happens. The Au$_4$ cluster deviates from the flat rhombus, thus beginning to have a 3D character, it is in the Au$_5$ where the 3D character is clearly obtained, forming triangular bipyramid. The study was done using the WIEN2k package.

*PAPIIT IN 115618
**H71.00184: Synthesis, Crystallography, Microstructure, Crystal defects and Optical Properties of (Fe-Ni) co-doped ZnO Thin Films prepared by sol–gel technique**

AHMAD ALSAAD (Presenter), QAIS AL-BATAINEH, A. AHMAD, A. BANI-SALAMEH, Jordan University of Science and Technology, Physics Department, ZAID ALBATAINEH, Department of Electronic Engineering, Yarmouk University, AHMAD TELFAH, Leibniz Institut für Analytische Wissenschaften — Zinc oxide (ZnO) and Iron-Nickel Fe-Ni co-doped ZnO thin films have been doped coated in glass sustrate using Sol Gel technique.

In addition, the microstructural properties and crystal imperfections of these samples were studied. X-ray diffraction (XRD) has been utilized to carry out these studies. XRD analysis revealed that these samples have a polycrystalline hexagonal wurtzite structure and nanometric dimensions. XRD-line profile analysis was used to study the microstructure and crystal defects of these nanoparticles. Crystallite size and microstrain were estimated using the Williamson–Hall method. It was observed that the crystallites sizes have increased as Fe-Ni concentrations were increased. However, strain in the thin films has decreased upon increasing Fe-Ni concentrations. Interestingly, the microstrain has decreased upon increasing Fe-Ni concentrations. The optical properties of the thin films were investigated using UV-Vis spectrometer measurements. The transmittance of the undoped ZnO was decreased upon increasing the concentration of Fe-Ni.

*Authors would like to thank Jordan University of Science and Technology for technical and financial support. We would like to thank Leibniz Institute in Germany for technical support.*

**H71.00185: Adsorption And Diffusion Properties of Aromatic Molecules on Silica/Ru(0001)**

MUHAMMAD SAJID (Presenter), WILLIAM KADEN, ABDELKADER KARA, Univ of Central Florida — Now a days, organic materials are replacing the conventional Si based ones in electronic devices due to being cheap, light weight and flexible. These devices are manufactured with metal contacts at both ends, providing support and/or electric conduction. Electronic properties at both ends are changed due to charge transfer at the interface affecting performance. In order to control charge transfer, we are investigating effects of inserting an inert layer separating the two. Using DFT with added vdW corrections and surface science spectroscopic techniques (XPS, LEED etc), we are studying adsorption of aromatic molecules on Ru(0001) with and without silica layer in between. Silica layer is shown to greatly inhibit adsorption strength and charge transfer at the interface. Using CI-NEB (Climbing Image Nudge Elastic Band) and TPD (Temperature Programmed Desorption) measurements, diffusion characteristics of molecules through pores of silica sheet and under the layer are thoroughly discussed. Comparison of simulation and experiment can provide better understanding of important processes at the interface.

*Partial support is from U.S. Department of Energy under Award number DE-SC0007045. Computational resources of NERSC and UCF-Stokes are used.*
H71.00186: Linking sprayability to thin-film performance in CNT-redox-polymer dispersions
KARTHIKA SURESH (Presenter), Chemical Engineering and Materials Science, University of Minnesota, Twin Cities, STEPHEN COTTY, XIAO SU, Department of Chemical & Biomolecular Engineering, University of Illinois, Urbana, MICHELLE A CALABRESE, Chemical Engineering and Materials Science, University of Minnesota, Twin Cities — Carbon nanotube (CNT)-loaded redox-polymer coatings are an attractive class of composite materials for charge storage devices, high-surface area ion-binding platforms, and selective redox mediated separation systems. While CNTs provides a nanoporous conductive network, the electroactivity of the redox-polymers grants these systems high pseudocapacitive charge-storage and ion recognition properties. Metallopolymers in particular are attractive due to their fast electron-transfer, synthetic tunability, and reversibility. However, processing CNT-metallopolymers to form uniform thin film coatings on large length scales is a substantial challenge. The sprayability, coatability, and printability of these dispersions are dictated by the extensional flow properties. Here, we link the extensional flow properties to the quality of the solution-processed thin film using capillary breakup extensional rheometry (CaBER) to capture filament formation and breakup. The CNT: polymer ratio, polymer molecular weight, polymer chemistry and solvent quality all impact the extensional rheology and corresponding thin film quality. Our results show a strong link between macroscopic flow properties, dispersion processability and final thin-film performance on the electrodes.

H71.00187: Oxidation of Tin as investigated by X-ray Photoelectron Spectroscopy*
ALLEN HILLEGAS, ANIL CHOURASIA (Presenter), Texas A&M University, Commerce — The oxidation of tin has been investigated by the technique of x-ray photoelectron spectroscopy. Thin films of tin were deposited on a silicon substrate by the e-beam technique. The films were oxidized in situ by exposing them to an atmosphere of oxygen at temperatures of 100, 200, 300, 400, and 500°C for various times. Aluminum x-rays (energy = 1486.6 eV) were used to record the spectra. The tin 3d and oxygen 1s core levels have been investigated. The spectral data (binding energy shift and the shape of the core level peaks) have been utilized to interpret the data. The growth of the oxide as a function of the substrate temperature and the oxygen pressure has been evaluated. The oxidation kinetics have been modelled to follow the growth of the oxide.

**H71.00188: Fabrization of giant piezoelectric material Sm-doped Pb(Mg_{1/3}Nb_{2/3})O_3-PbTiO_3 single crystal film**

YIFEI FANG (Presenter), MIN XU, YIN HANG, Key Laboratory of High Power Laser Materials, Shanghai Institute of Optics and Fine Mechanics, Chinese Academy of Sciences — Sm-doped Pb(Mg_{1/3}Nb_{2/3})O_3-PbTiO_3 (Sm-PMN-PT) single crystal was recently reported as a new piezoelectric material with the highest piezoelectric charge coefficients which will have great applications on transducers and sensors in electromechanics [1]. In previous research, the piezoelectric mechanism in the material is believed that the local structural heterogeneity of relaxor ferroelectric crystals caused by Rare-earth element. However, the research on the thin film of this material is still lack. For further investigate the piezoelectric properties of Sm-PMN-PT thin film, we explored the methods to grow Sm-PMN-PT film on different substrates, such as YAlO_3, MgAl_2O_4, MgO. Furthermore, we analyzed and compared the differences in the transport properties and crystal structure between Sm-PMN-PT layers deposited onto different substrates. According to the calculation in Ref. [1], La^{3+} and Nd^{3+} was considered substituting the Sm ions in our future work. This research will promote the development of advanced piezoelectric devices.

**H71.00189: Fabrication of (Ga_{2}O_3)_{x}(Fe/Cr)_{y}(ZnSeTe /ZnSTe)_{1-x-y} film on quartz substrate**

YIFEI FANG (Presenter), SHULONG ZHANG, MIN XU, YIN HANG, Key Laboratory of High Power Laser Materials, Shanghai Institute of Optics and Fine Mechanics, Chinese Academy of Sciences — Mid-IR (MIR) band at ~3μm has attracted much attention for their wide applications in medical, biological, sensing technologies, etc. Ga_{2}O_3 is a wide band gap semiconductor material with fine electrical and luminescent properties, which has been widely used in photoelectric devices. Recently, an intriguing material (In_{2}O_3/Ga_{2}O_3)_{0.1}(Co)_{0.5}(ZnS/Se)_{0.4} has been reported[1] that which owns better optical and transport properties than its parent phase of Ga_{2}O_3 and In_{2}O_3. According to Ref [1], the reason of doping Co was the rich absorption and emission levels, good infrared optical properties, and room temperature ferromagnetic (RT-FM) property. However, compared with Co, transition metal Fe and Cr have wider FWHM of absorption, emission and luminescence spectrum, and even Fe has stronger RT-FM property than Co. Moreover, the different chalcogenide elements substitution might induce abundant properties which has been already verified by many researches in correlated system[2]. Hereby, we synthesized (Ga_{2}O_3)_{x}(Fe/Cr)_{y}(ZnSeTe /ZnSTe)_{1-x-y} film onto quartz substrate and investigated the structure, optical and transport properties.

**H71.00190: A route to atomically flat TiO2 terminated surfaces in SrTiO3 avoiding HF acid.**

DAKOTA BROWN (Presenter), JAMES PAYNE, MAITRI WARUSAWITHANA, Univ of North Florida — SrTiO3, known as a quantum paraelectric, is a very interesting quantum system. At the same time it is a widely used substrate to grow epitaxial oxide thin films. For the growth of high quality films and superlattices, it is imperative to have an atomically flat starting surface with a known surface termination. While the main technique for obtaining quasi-ideal SrTiO3 surfaces for growth of epitaxial thin films has been via an etching step that involves HF acid [Appl. Phys. Lett. 73, 2920 (1998)] followed by an anneal in flowing oxygen to around 1000 C, here we discuss an alternate process for obtaining atomically flat surfaces. Our process involves etching in a dilute HCl acid solution, which is known as a polishing etch for SrTiO3, and eliminates the use of HF acid and the need for the high temperature (1000 C) anneal. We will compare atomic force microscopy and RHEED images of SrTiO3 substrates prepared with our process involving dilute HCl acid with those prepared using the method involving HF acid. Our controlled experiments suggest that this process provides extremely smooth surfaces with very sharp step edges that are mostly oriented parallel to the crystallographic axes.

*Department of Physics, University of North Florida

**H71.00191: Intrinsic magnetic topological insulator phases in the Sb doped MnBi$_2$Te$_4$ bulks and thin flakes**

BO CHEN (Presenter), FUCONG FEI, FENGQI SONG, Nanjing Univ — Magnetic topological insulators (MTIs) offer a combination of topologically nontrivial characteristics and magnetic order and show promise in terms of potentially interesting physical phenomena such as the quantum anomalous Hall (QAH) effect and topological axion insulating states. However, the understanding of their properties and potential applications have been limited due to a lack of suitable candidates for MTIs. Here, we grow two-dimensional single crystals of Mn(Sb$_x$Bi$_{(1-x)}$)$_2$Te$_4$ bulk and exfoliate them into thin flakes in order to search for intrinsic MTIs. We perform angle-resolved photoemission spectroscopy, low-temperature transport measurements, and first-principles calculations to investigate the band structure, transport properties, and magnetism of this family of materials, as well as the evolution of their topological properties. We find that there exists an optimized MTI zone in the Mn(Sb$_x$Bi$_{(1-x)}$)$_2$Te$_4$ phase diagram, which could possibly host a high-temperature QAH phase, offering a promising avenue for new device applications.
**H71.00192: Gate-controlled anomalous Hall effect reversal in the magnetic topological insulator MnBi$_2$Te$_4$ device**

SHUAI ZHANG (Presenter), Nanjing Univ — Magnetic topological insulator, a platform for realizing quantum anomalous Hall effect, axion state and other novel quantum transport phenomena, has attracted a lot of interest. Recently, it is proposed that MnBi$_2$Te$_4$ is an intrinsic magnetic topological insulator, which may overcome the disadvantages in the magnetic doped topological insulator, such as disorder. Here we report on the gate-reserved anomalous Hall effect (AHE) in the MnBi$_2$Te$_4$ thin film. By tuning the Fermi level using the top/bottom gate, the AHE loop gradually decreases to zero and the sign is reversed. The positive AHE exhibits distinct coercive fields compared with the negative AHE. It reaches a maximum inside the gap of the Dirac cone, and its amplitude exhibits a linear scaling with the longitudinal conductance. The positive AHE is attributed to the competition of the intrinsic Berry curvature and the extrinsic skew scattering.

**H71.00193: Preparation of Few quintuple layers Bismuth selenide (Bi$_2$Se$_3$) by spin coated-coreduction approach (SCCA) and Optical nonlinearity was discussed**

WEI-HENG SUNG (Presenter), HSUAN-SEN WANG, Department of photonics, National Sun Yat-sen University, YUE ZHOU, Department of Physics, Jiangsu University of Science and Technology, HONG LIU, State Key Laboratory of Crystal Materials, Shandong University, CHAO-KUEI LEE, Department of photonics, National Sun Yat-sen University — Topological insulators (TIs) have been realized their functionality of saturation absorption (SA) for pulsing lasers. Recently, using spin coated-coreduction approach (SCCA) growth Bi$_2$Te$_3$ thin film, continuous wave mode locking (CWML) solid state laser with repetition rate as high as GHz has been demonstrated. Compared to Bi$_2$Te$_3$, Bi$_2$Se$_3$ has been theoretically and experimentally investigated with p-type nature, leading to greater potential to be a SA. However, the difficulty of preparing high optical thin film results in the less report about their application for pulsed lasers. In this study, large area topological insulator thin film Bi$_2$Se$_3$ (Bismuth Selenide) of few quintuple layers were prepared by spin coated-coreduction approach (SCCA). AFM image, TEM image, XPS, XRD, Raman pattern all show that the growth Bi$_2$Se$_3$ thin film is with high crystalline quality. In addition, the application of Bi$_2$Se$_3$ for pulsing solid state laser was studied and discussed as well.

H71.00194: Role of polarization force for coherent phonon generation within the Bi$_2$Te$_3$ thin film  MENG-CHING LEE (Presenter), TSUN-I CHEN, JIN-WEI LI, CHAO-KUEI LEE, Department of Photonics, National Sun Yat-sen University — To date, the generation mechanism of coherent phonon within the topological insulators is an important but still unconfirmed topic. In this work, using double pulse technique, the dynamic properties and possible mechanisms of the coherent phonon($A_{1g}^1$, $A_{1g}^2$, $E_{g}^2$) in Bi$_2$Te$_3$ were investigated. Among these three phonon modes, decreasing intensity and frequency as increasing temperature was observed, which can be attributed to the reducing temperature gradient, leading to thermal force generation mechanism. However, by analyzing the temporal evolution of the phonon frequency, the frequency of $E_{g}^2$ was gradually shifted to higher frequency rather than red shift trend observed in the $A_{1g}^1$ and $A_{1g}^2$. This indicates that an additional way for generating $E_{g}^2$ mode with nature of an-harmonicity might be inevitable. Here, the polarization force mechanism for $E_{g}^2$ mode was proposed and discussed in detail.

H71.00195: Strain induced tuning and annihilation of Dirac point in the topological insulator Bi$_2$Se$_3$ (001) surface.  SOUMENDRA DAS (Presenter), PRAHALLAD PADHAN, Indian Inst of Tech-Madras — Engineering the band gap and tuning the Dirac point (DP) of (001) surface of the 8 quintuple layers (QLs) thick Bi$_2$Se$_3$ were investigated by varying the strain through first principle density functional theory calculations, with and without the presence of spin-orbit coupling (SOC). The strain on the Bi$_2$Se$_3$ (001) surface primarily varies the band width, which changes the orbital population in the conduction and valence band. The tuning of the $p_z$ - orbital population of Bi on the (001) surface of the Bi$_2$Se$_3$ froms the Dirac cone at the $\Gamma$ point, which can be achieved under uniaxial, biaxial or volume conservation strain. Around 6% out-of-plane tensile strain annihilates the DP of the (001) surface of the Bi$_2$Se$_3$ which causes the loss of topological surface states. The anniliation of the DP occurs even at lower values of volume conservation strain. However, the DP feature is preserved for the entire range of biaxial strain. The DP moves towards the Fermi level for the increasing tensile strain under uniaxial and volume conservation configuration, but the similar displacement of DP occurs due to increasing compressive biaxial strain. The tuning of DP may provide a new pathway to control many physical properties of Bi$_2$Se$_3$ and shed light for its technological applications.

H71.00196: WITHDRAWN ABSTRACT  DONNA GREENE (Presenter), American Physical Society —
H71.00197: Core Reconstruction of Dislocations in layered-chalcogenide semiconductors (Bi2X3 - X = Te, Se, and S)*  
NESTOR FAJARDO (Presenter), RICARDO NUNES, Physics Department, UFMG - Brazil — The interest in the layered chalcogenide family Bi2X3 (X = Te, Se, and S) is due to their thermoelectric properties and the topology of their electronic structure. Understanding scattering of electronic carriers and phonons in such materials is crucial for devising strategies to improve their thermoelectric properties. A crucial step is the identification of the reconstruction patterns in the core of dislocations in these covalently-bonded systems. In this work, we investigate the single- and double-period core reconstruction of the 60-degree and the screw dislocations - both with Burguers vector parallel to the basal plane - in these materials. Issues of dissociation of the 60-degree and the screw dislocations into 30-degree and 90-degree partial dislocations will also be discussed.

H71.00199: Refinement of High-Throughput Calculations for Rare Earth Topological Insulators  
GAVIN NOP (Presenter), JONATHAN SMITH, Iowa State University — Topological Insulators (TI) have become increasingly important in the condensed matter science of electronic band theory. We focus on inorganic topological insulators using advancements in “Topological Quantum Chemistry” (TQC) [Bradlyn et al., Nature 547, 298 (2017)], combined with “A Complete Catalog of High-Quality Topological Materials” [Vergniory et al., Nature 566, 480 (2019)], to narrow our search to predicted topological insulators. In the latter paper, a high-throughput calculation of electronic band structure was used to predict TI’s. The inorganic topological materials were down-selected to rare earth materials which require on-site electron correlation and spin orbit coupling to verify their band topology. To keep computations feasible, we restrict our materials search to binary and ternary compounds with appropriate crystal structures. Rare earth materials require high-quality density functional theory calculations in order to compute their electronic band structure. We produce such high-quality calculations for a down-selected representative set of rare earth crystals in order to refine and correct the TQC high-throughput predictions. G.N. is grateful for an assistantship in the US DOE Office of Science, Science Undergraduate Laboratory Internship program.
H71.00200: Aubry-Andre-Harper Model with on-site hopping and p-wave pairing*
MOHAMMAD YAHYAVI, BALAZS HETENYI, BILAL TANATAR (Presenter), Department of Physics, Bilkent University — We study an extended Aubry-André-Harper model with simultaneous modulation of hopping on-site potential and p-wave superconducting pairing. For the case of commensurate modulation of $\beta=1/2$ it is shown that the model hosts four different types of topological states: Adiabatic cycles can be defined which pump particles two types of Majorana fermions or Cooper pairs. In the incommensurate case we calculate the phase diagram of the model in several regions. We characterize the phases by calculating the mean inverse participation ratio and perform multifractal analysis. In addition we characterize whether the phases found are topologically trivial or not. We find an interesting critical extended phase when incommensurate hopping modulation is present. The rise between the inverse participation ratio in regions separating localized and extended states is gradual rather than sharp. When in addition the on-site potential modulation is incommensurate we find several sharp rises and falls in the inverse participation ratio. In these two cases all different phases exhibit topological edge states.

*This work is funded by TUBITAK and TUBA.

H71.00201: Dipolar Magnetoexcitons in $\alpha$-$T_3$ double layers in a high magnetic field
YONATAN ABRANYOS (Presenter), GODFREY GUMBS, Physics and Astronomy, Hunter College of CUNY, OLEG BERMAN, Physics, New York City College of Technology — We consider two parallel $\alpha$-$T_3$ layers separated by an insulating slab (e.g. SiO$_2$ or a hexagonal boron nitride (h-BN) insulating barrier) in a high magnetic field. The equilibrium system of local pairs of electrons and holes, spatially separated in these parallel $\alpha$-$T_3$ layers, correspondingly, can be created by varying the chemical potential using a bias voltage between two $\alpha$-$T_3$ layers or between two gates located near the corresponding $\alpha$-$T_3$ sheets (case 1) (for simplicity, we also call these equilibrium local e-h pairs as dipolar magnetoexcitons). In case 1 a dipolar magnetoexciton is formed by an electron on the Landau level 1 and hole on the Landau level $-1$. Dipolar magnetoexcitons with spatially separated electrons and holes can be created also by laser pumping (case 2) and by applying a perpendicular electric field. In case 2, a dipolar magnetoexciton is formed by an electron in the Landau level 1 and hole in the Landau level 0. We assume the system is in a quasi-equilibrium state. We study the collective properties and superfluidity of dipolar excitons in $\alpha$-$T_3$ double layers in a high magnetic field for both case 1 and case 2.
H71.00202: Smooth Evolution in Hall Coefficient in the Overdoped Cuprate Tl2201
CARSTEN PUTZKE (Presenter), University of Bristol, SIHAM BENHABIB, WOJCIECH TABIS, LNCMI Toulouse, JAKE AYRES, LIAM MALONE, University of Bristol, NIGEL HUSSEY, HFML Nijmegen - Radboud University, JOHN R. COOPER, University of Cambridge, ANTONY CARRINGTON, University of Bristol — Our understanding of the microscopic origin of superconductivity in the cuprates is dependent on our knowledge of the normal state. Recently a sharp transition in the carrier density was proposed, close to optimal doping in YBa$_2$Cu$_3$O$_{6+\delta}$ and Nd-doped La$_{2-x}$Sr$_x$CuO$_{4.1,2}$. This transition was argued to be tied to the Pseudogap endpoint $p^*$. Here we report a study of the high field Hall coefficient of the single-layer cuprate Tl$_2$Ba$_2$CuO$_{6+\delta}$ (Tl2201) which shows that $n_H(0)$ evolves smoothly in the overdoped, so-called strange metal, phase of cuprates. No evidence for a Pseudogap has to date been reported in this material. This raises the question for a universality of the proposed link between the Pseudogap endpoint and the transition in carrier density, from $p$ to $1+p$, inferred from the Hall coefficient. Rather the evolution of $n_H$ seems to correlate with the emergence of the anomalous linear-in-$T$ term in the in-plane resistivity. The presented data will shed new light on the evolution that the cuprates take from a Fermi liquid behavior to a strongly correlated, highly complex behavior in the underdoped side of the phase diagram.

H71.00203: Exploring the Josephson Scanning Tunneling Microscopy: Towards a Phase-Coherent Junction
MICHAEL DREYER, JOSEPH MURRAY (Presenter), WAN-TING LIAO, Laboratory for Physical Sciences, SUDEEP DUTTA, CHRISTOPHER J LOBB, FREDERICK C WELLSTOOD, University of Maryland College Park, ROBERT E BUTERA, Laboratory for Physical Sciences — Josephson scanning tunneling microscopy (JSTM) is performed by using a superconducting tip on a superconducting sample. The resulting Josephson junction (JJ) is usually too small in terms of critical current and capacitance to support phase coherence between the two superconductors. We are pursuing a concept to overcome that limitation by stabilizing the phase in the scanning junction with a larger JJ in a SQUID loop. We employ a home-built dual-tip STM with connected tips to implement the concept. We characterize the individual junctions by measuring standard $I(V)$ and $dI/dV$ curves, as well as $V(I)$ characteristics which are more common to the study of JJs. In the SQUID configuration, a flux bias of the SQUID should lead to a modulation of the critical current, thus proving the concept.
H71.00205: Mapping out the electronic and magnetic transitions in mixed-valent La$_{1-x}$Sr$_x$MnO$_3$ thin films*  JAMES PAYNE (Presenter), DAKOTA BROWN, THOMAS PEKAREK, MAITRI WARUSAWITHANA, Univ of North Florida — The rich phase diagram in mixed-valent manganites has been intensely studied in bulk crystals as a function of chemical doping. Here we study the effect of doping in La$_{1-x}$Sr$_x$MnO$_3$ thin films by varying the Sr/La ratio between samples. These thin films are grown using ozone assisted molecular beam epitaxy with carefully controlled stoichiometry for a range of doping from x = 0.0 to x = 0.5. Our electronic measurements reveal a crossover from a Mott insulator to a metallic ground state as x is increased. In the metallic ground state we observe a metal-to-insulator transition coincident with a ferromagnetic-to-paramagnetic ordering transition consistent with the double exchange interaction with higher, doping dependent transition temperatures compared to those reported for bulk La$_{1-x}$Sr$_x$MnO$_3$ crystals. We will also discuss the magnetic ordering transitions observed in the low doping regime (x<0.17) where an insulating ground state is observed and compare these transitions with those reported for bulk La$_{1-x}$Sr$_x$MnO$_3$ crystals.

H71.00206: Temperature-dependent Raman studies of a natural van der Waals heterostructure*  VIVIANE ZURDO COSTA (Presenter), Physics and Astronomy, San Francisco State University, SAM VAZIRI, Electrical Engineering, Stanford University, SHIRIN JAMALI, ADDISON MILLER, Physics and Astronomy, San Francisco State University, ANDREW IchIMURA, Chemistry and Biochemistry, San Francisco State University, ERIC POP, Electrical Engineering, Stanford University, AKM SHAH NEWAZ, Physics and Astronomy, San Francisco State University — Van der Waals heterostructures (vdWH) comprised of two-dimensional (2D) materials offer a platform to obtain designed materials with unique electronic properties. Research on 2D vdWH has so far been focused on fabricating such heterostructures by stacking individual 2D crystals, which leads to stacks with the presence of fabrication defects. Franckeite (Fr) is a naturally occurring vdWH comprised of two different alternately stacking semiconducting layers, that enables the study of a complex layered system where the crystal orientation between layers has been preserved. Unlike other layered sulfide-based materials, Fr is a grained-textured rock composed of few-millimeter flakes in random orientation. For this reason, exfoliation of thin flakes with a uniform and large surface area for optical characterization and transfer techniques is especially challenging. By precise manipulation of the starting flake in combination with different substrates we were able to increase the quality of exfoliation and obtain few-layer (< 5) Franckeite flakes with uniform surface areas of approximately 5 μm. Here we present results on the developed exfoliation technique and temperature-dependent Raman spectroscopy of Franckeite.

H71.00207: Magnetism-induced Raman modes in two-dimensional CrI\textsubscript{3} atomic layers*
GAIHUA YE (Presenter), ZHIPENG YE, RUI HE, Texas Tech Univ, HYUN HO KIM, BOWEN YANG, ADAM TSEN, University of Waterloo, Canada, WENCAN JIN, SIWEN LI, LIUYAN ZHAO, University of Michigan — We studied CrI\textsubscript{3} atomic layers down to the monolayer limit using temperature and magnetic field dependent micro-Raman spectroscopy. Two sets of Raman modes at frequencies of ~76 and ~125 cm\textsuperscript{-1} are observed in CrI\textsubscript{3} atomic layers only in the antisymmetric channel below the magnetic phase transition temperature, suggesting that these two modes are related to the broken time reversal symmetry in the samples. By tracking the thickness dependence of both modes, we reveal that they are of the surface nature. Magnetic field dependent measurements of bilayer CrI\textsubscript{3} at 10 K further show that these modes disappear above the critical field of ~0.8 T. Possible origin of these two Raman modes is proposed.

H71.00208: Strain tuned structural phase transition and optical switching in 1T-ZrS\textsubscript{2} and 1T-ZrSe\textsubscript{2}  
EDOARDO MARTINO (Presenter), Ecole Polytechnique Federale de Lausanne, FLORIAN LE MARDELÉ, University of Fribourg, KONSTANTIN SEMENIUK, Ecole Polytechnique Federale de Lausanne, DAVID SANTOS-COTTIN, University of Fribourg, FRANCESCO CAPITANI, Soleil Synchrotron, HELMUTH BERGER, LASZLO FORRO, Ecole Polytechnique Federale de Lausanne, ANA AKRAP, University of Fribourg — Strain is a versatile and powerful tool to manipulate electronic properties of 2D-materials. In addition to continuous tuning of the electronic band-structure, applied strain can drive a structural phase transition, generating new states with drastically different optical and electronic properties. While this has not been observed in the most actively investigated semiconducting transition metal dichalcogenides, 2H-MoS\textsubscript{2} and 2H-WSe\textsubscript{2}, we found strain-induced structural phase transitions to take place in 1T-ZrS\textsubscript{2} and 1T-ZrSe\textsubscript{2}, which possess optical and electronic properties similar to those of Mo- and W- compounds, but have different crystalline structure and orbital character. Our high-pressure Raman scattering, X-ray diffraction and optical absorption experiments revealed a reversible metallization of 1T-ZrSe\textsubscript{2} at 8 GPa and an irreversible transformation of 1T-ZrS\textsubscript{2} to a new semiconducting phase at 3 GPa, with smaller band gap by 1 eV (from 1.7 eV to 0.7 eV), a change that is optically evident. The study is complemented by structural investigation under pressure and \textit{ab initio} band structure calculations.

H71.00209: WITHDRAWN ABSTRACT —
H71.00210: Electrostatically control interfacial states for stackable electronics*  CHEN PO-HAN (Presenter), YU-TING LIN, CHUN-AN CHEN, YI-CHENG CHIANG, I-TUNG CHEN, YI-HSIEN LEE, National Tsing-Hua University — Semiconducting monolayer of transition metal dichalcogenides (TMD) is ideal fundamental unit for stackable electronics because of its excellent optoelectronic properties. However, further applications are hindered with various issues from trap states of the monolayers. Here we develop a method to effectively engineer trap states of the monolayer MoS2 for excellent optoelectronic performances, including ultrahigh photoresponsivity (R) of $10^2$–$10^4$ A/W, high sensitivity (D*) of $10^{11}$–$10^{12}$ Jones and large absorbance. A scalable image sensor array of CVD-grown MoS2 monolayer is demonstrated.

*AOARD grant (co-funded with ONRG) FA2386-16-1-4009

H71.00211: Large-Scale Synthesis of MoS$_2$ One-dimensional Nanostructures and Precision Manipulation*  YUN HUANG, ZEXI LIANG, KANG YU, University of Texas at Austin, PAULO FERREIRA, The department of Advanced Electron Microscopy, International Iberian Nanotechnology Laboratory, DONGLEI (EMMA) FAN (Presenter), University of Texas at Austin — In the family of two dimensional (2D) materials, molybdenum disulfide (MoS$_2$) has received immerse attention. Herein, we report a scalable approach to synthesize MoS$_2$ nanoribbons with controlled dimensions. Characterizations confirm the chemistry, morphology, and crystalline structures of materials obtained at different reaction stages, including MoO$_3$, MoS$_2$/MoO$_2$ hybrid, and MoS$_2$ nanoribbons. With the electric tweezers based on combined AC and DC electric fields, the MoS$_2$ nanoribbons can be readily manipulated with desired orientations along arbitrary trajectories, e.g. along a cat drawing. Moreover, it is found that the electromechanical behaviors of the particles obtained at different growth stages strongly correlate with their electric properties, the demonstration of which could be utilized to monitor and understand the synthetic process of targeted nanomaterials. This work may lead to a new paradigm in the large-scale fabrication of 2D materials with designed dimensions and inspire their innovative applications in nanorobotics, micro/nanoelectromechanical system devices (MEMS/NEMS), as well as molecule delivery and release.

H71.00212: First Principles Electronic and Lattice Dynamics Calculations of TiSe$_2$ and TiTe$_2$

WARDA RAHIM (Presenter), University College London, PHILIP KING, University of St. Andrews, DAVID SCANLON, University College London — TiSe$_2$ bulk and monolayer both undergo a charge density wave (CDW) instability,$^{1,2}$ whereas only monolayer TiTe$_2$ undergoes a CDW transition.$^3$ We performed electronic structure and lattice dynamics calculations (Phonopy code)$^4$ for both of these Ti(IV) dichalcogenides using hybrid (HSE06)$^5$ density functional theory. We also mapped the potential energy surfaces$^6$ spanned by the imaginary mode eigenvectors to estimate the barrier associated with the transition and to track the route to the CDW phase. Our results successfully show that though TiTe$_2$ bulk has no lattice instability, its monolayer has an instability similar to, but much weaker than that seen in TiSe$_2$, highlighting the origin of a weak coupling CDW distortion brought about by a lattice instability. These results could have impact in understanding of CDW instabilities in other systems, particularly the methodology of following imaginary modes to track the transitions between phases.

H71.00213: Controlling the stereospecific bonding motif of Au-thiolate links and assessment of their catalytic properties* MOHAMMED SABRI G. MOHAMMED (Presenter), LUCIANO COLAZZO, Donostia International Physics Center, AURELIO GALLARDO, The Czech Academy of Sciences, ZAKARIA M ABD EL-FATTAH, Al-Azhar University, JOSÉ A. POMPOSO, Centro de Física de Materiales (CFM-MPC), CSIC-UPV/EHU, PAVEL JELÍNEK, The Czech Academy of Sciences, DIMAS GARCÍA DE OTEYZA, Donostia International Physics Center — Organosulfur compounds at the interface of noble metals have long been proved to be extremely versatile systems. In this work we explore the formation of gold-thiolate-based organometallic structures from 1,4-bis(4-mercaptophenyl)benzene (BMB) deposited onto Au(111) surface. By controlling the on-surface reaction conditions we can selectively choose the resulting structures to be either arrays of cyclic Au$_3$BMB$_3$ units or linearly stacked nanowires, although the former turn out to be the thermodynamically favored products[1]. Most interestingly, co-deposition of alkyne-functionalized pyrene derivatives on this system reveals the catalytic activity of the R-S-Au-S-R vertices on alkyne coupling reactions.

H71.00214: Optimal $U$ values for 3$d$ transition metal oxides within a SCAN+$U$ framework

SAI GAUTAM GOPALAKRISHNAN (Presenter), Mechanical and Aerospace Engineering, Princeton University, OLIVIA LONG, Physics, Princeton University, EMILY CARTER, Office of Chancellor, University of California Los Angeles — Redox-active transition metal oxides that can tolerate oxygen off-stoichiometry are crucial ingredients for generating renewable fuels via oxide-based solar thermochemical reactors. However, any predictive modeling, such as using density functional theory (DFT) calculations, needs to accurately describe the energetics of redox reactions involving transition metals, if new candidates are to be found. Recently, we found that the strongly constrained and appropriately normed (SCAN) exchange-correlation functional requires a Hubbard $U$ correction (determined, e.g., from experimental oxidation enthalpies) to accurately describe the ground state structure, magnetic moments, and electronic properties of Ce-, Mn-, and Fe-based systems. In the present work, we extend our approach to identify optimal $U$ values for other 3$d$ oxides within the SCAN+$U$ framework. Although the absolute magnitude of $U$ values required for all 3$d$ metals is lower than what is needed using a generalized gradient approximation+$U$ or a local density approximation+$U$ approach, we find that the addition of $U$ makes non-negligible improvements in ground state property predictions, particularly for Ti, V, Co, and Ni oxides, highlighting the importance of using a SCAN+$U$ framework.

H71.00215: Polarization dependence photoluminescence in flexible two-dimensional MoS$_2$ for lattice deformation characterization

YANGBOWEN LIU (Presenter), XIAN ZHANG, Mechanical Engineering, Stevens Inst of Tech — Since Nobel Physics Prize in 2010 about graphene, intense research endeavors have been paid worldwide to comprehend the intrinsic characteristics of two-dimensional (2D) materials and explore their cutting-edge applications in bioengineering, energy storage and conversion, and nanoelectronics. 2D heterostructures consisting of various 2D materials are receiving extensive interests nowadays. However, there is a lattice deformation when different 2D materials are stacked together. Characterization of each 2D layer’s lattice deformation facilitates with the optimized 2D device design. In this project, we study the rotation angle dependent photoluminescence (PL) of one atomic layer of 2D MoS$_2$ under a serious of external mechanical deformations. The PL shows a dependence with the sample rotation angle at stretched status. The intensities of two PL peaks (627 nm and 679 nm) have strong angle dependence and a serious of mechanical deformations (up to 10%) are performed. This research result can be used to accurately identify the value of lattice deformation in 2D heterostructures.

**H71.00216: Optical measurements on phosphorus polymorphs.** CARLOS JOSAFAT CORDERO SILIS (Presenter), ELIZABETH CHAVIRA, Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México, THOMAS STEGMANN, Instituto de Ciencias Físicas, Universidad Nacional Autónoma de México, ADRIANA TEJEDA CRUZ, KARLA ERISETH REYES MORALES, MIGUEL ÁNGEL CANSECO MARTÍNEZ, Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México — The anisotropic electronic structure of phosphorene makes it promising, for research and technological applications. Its polymorphs are White Phosphorus, which transforms into Red or Violet at 280 °C and 550 °C, and Black Phosphorus obtained from White applying pressure (12000 Bar) or trough catalysis. This research focuses on alternative synthesis methods for these, given their prohibitive cost, using common available materials.

Method 1: Matches’ heads were crushed with a blade to detach the material; it is then combusted in a Petri dish, mixed in 5 mL methanol for 30 h, at 26-32 °C, 45-47% humidity, and ground to a fine powder in an agate mortar. 146 mg were heated to 200 °C/65 h.

Method 2: Using tweezers and a cotton swab the strips are covered with acetone for a few seconds and scraped. The material is mixed in 20 mL acetone for 2 h, at 24 °C, 45 % humidity, air dried and ground to a fine powder. 118 mg were heated to 200 °C/65 h.

X-ray powder diffraction (XRD) analysis of the samples shows, for Method 1: SrP, Sr3P4O13, P2O5 and Sr2BrP. For Method 2: PBr5, and SrP. Simultaneous calorimetric and thermogravimetric analysis show the binary and ternary compounds observed by XRD. UV-Vis analysis shows the influence of the polymorphs and other impurities. Color changes are present.

**H71.00217: In-situ measurement of strain evolution in 2D materials on flexible substrates using Raman spectroscopy.** MARC MEZZACAPPA (Presenter), Mechanical Engineering, Saint Louis University, HENRY WRIGHT, DHEYAA ALAMERI, Physics, Saint Louis University, MARY CONLEY, Physics, Chemistry, Saint Louis University, CHI HOU LEI, Mechanical Engineering, Saint Louis University, IRMA KULJANISHVILI, Physics, Saint Louis University — Since its recent discovery, extensive research investigating the physical properties of Graphene and other similar two-dimensional (2D) materials has been performed. Graphene’s excellent mechanical properties, flexibility, and optical transparency make it a promising candidate for a variety of layered architectures and hybrid devices. A custom low profile testing device was designed and manufactured in-house for in-situ physical measurements of single and multilayer 2D materials on flexible substrates using Raman spectroscopy. The design of the device allows for accurate and consistent strain application of both uniaxial bending and uniaxial tension in 2D materials. Here we use the device to investigate bending induced strain evolution in 2D materials through observation of characteristic Raman spectra band shifts. 2D materials used here were prepared via chemical vapor deposition (CVD) and were transferred to the flexible substrates. Our results provide information on strain development, substrate interaction, and adhesion properties of the 2D material tested.

The electron transparency of graphene is investigated using Hemispherical Energy Analyzer. We further compare the results to numerically obtained values and find excellent agreement between the two. The measurements and calculations demonstrated that graphene is an excellent electron transparent material even at low electron kinetic energies where the transmission exceeds 90% with 12-eV energy. The experimental data and the model is used to extract the parameters of the experimental setup. There are some discrepancies about electron transparency of graphene in literature. By, detailed analysis, we showed that these are due to the sensitivity of the transmission on the experimental setup.

H71.00219: Structural, electronic, and optical properties of defect-containing MX2 monolayers from first principles*  JARON KROPP (Presenter), CAN ATACA, Univ of Maryland-Baltimore County — In this work, we investigate the role of defects on the modification of the structural, electronic, and optical properties of transition metal dichalcogenide (MX2: M=Mo,W; X=S,Se) nanosheets. Using the cluster expansion formalism and density functional theory (DFT), we calculate the energetics and magnetic ordering of MX2 monolayers with various concentrations of chalcogen vacancies. The energetically favorable structures with desired vacancy concentration are then investigated further to determine the effects on the electronic, magnetic, and optical properties including the exciton binding energies. The structures we obtained from cluster expansion are then used as training sets for our machine learning algorithm to predict large scale MX2 monolayers with desired vacancy concentration. We employ classical molecular dynamic simulations to study in the effect of vacancy defect concentration on the structural deformation of freestanding MX2 nanosheets and nanoribbons. We report that after certain vacancy concentration values, MX2 monolayers deform from planar structures to buckled structures. This work not only provides insight into realistic (i.e. CVD grown) MX2 monolayers, but also provides guidance for defect engineering for device applications of MX2 structures.

*NSF DMR-1726213
**H71.00220: Superconductivity in layered misfit chalcogenide BiSe-NbSe\(2\)**  
KAYA KOBAYASHI (Presenter), MASAHARU SHIRATA, JUN AKIMITSU, Okayama Univ — Layered misfit chalcogenides, (BiSe)\(_{1+\delta}\)(NbSe\(_2\)) is an anisotropic superconductor (T\(c=2.3\) K)\([1]\). The superconductivity is mostly carried out in NbSe\(_2\) layers, *i.e.* a superconducting NbSe\(_2\) layer is sandwiched by insulating BiSe layers. The situation for NbSe\(_2\) resembles the monolayer on a substrate, albeit the slight charge transfer is discussed from BiSe layers. We report the new structure of the series of the material, (BiSe)\(_{1+\delta}\)(NbSe\(_2\))\(_n\), and the enhancement of T\(c\) as the number of NbSe\(_2\) layers (n) increases.

*This work is supported by Grants-in-Aid for Scientific Research (Grant No. 18K03540, 19H01852).

**H71.00221: Piezoelectric domain walls in van der Waals ferroelectric CuInP\(_2\)Se\(_6\)**  
ANDRIUS DZIAUGYS, Vilnius University, JOHN A BREHM, Vanderbilt University, ALEX A PURETZKY, Oak Ridge National Lab, TIANLI FENG, Vanderbilt University, SABINE M. NEUMAYER, Oak Ridge National Lab, EUGENE ELISEEV, National Academy of Sciences of Ukraine, JURAS BANYS, Vilnius University, YULIAN VYSOCHANSKII, Institute of Solid State Physics and Chemistry, Uzhgorod, Ukraine, MICHAEL MCGUIRE, SERGEI V. KALININ, Oak Ridge National Lab, SOKRATES T PANTELIDES, Vanderbilt University, NINA BALKE, Oak Ridge National Lab, ANNA MOROZOVSKA, National Academy of Sciences of Ukraine, MICHAEL MCGUIRE, SERGEI V. KALININ, Oak Ridge National Lab, SOKRATES T PANTELIDES, Vanderbilt University, NINA BALKE, Oak Ridge National Lab, ANNA MOROZOVSKA, National Academy of Sciences of Ukraine, PETRO MAKSYMOVYCH (Presenter), Oak Ridge National Lab — Van der Waals layered chalcogenophosphates, such as CuInP\(_2\)S\(_6\) and AgInP\(_2\)S\(_6\), exhibit intriguing polar properties such as room temperature ferrielectric ordering, negative electrostriction, large elastic nonlinearity, proximity to ionic conductivity and multi-well ferroelectric potential, presumably due to a unique influence of the van der Waals gap. Here we will discuss anomalous properties of domain walls in ferrielectric selenophosphate CuInP\(_2\)Se\(_6\) detected using piezoresponse force microscopy. Whereas in ferroelectrics, including a structurally similar case of ferrielectric CuInP\(_2\)S\(_6\), electromechanical response and polarization vanish at the domain wall, the reverse is true in the case of CuInP\(_2\)Se\(_6\), so that piezoresponse vanishes everywhere but the domain wall. And yet, these domain walls can be manipulated by electric field. We propose the existence of an antiferroelectric phase in the near-surface layer of CuInP\(_2\)Se\(_6\), with locally enhanced polarization at antiferroelectric domain walls. Nature Comms. in review (2019).

*Experiments carried out at the Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, with addition support from CIEE / Baltic-American Freedom Foundation, DOE MSE at ORNL and University of Vanderbilt.
**H71.00222: Synthesis of Semiconducting Graphene Nanoribbons via Chemical Vapor Deposition**

ROBERT JACOBBERGER (Presenter), AUSTIN J WAY, VIVEK SARASWAT, MICHAEL ARNOLD, University of Wisconsin - Madison — Graphene nanoribbons (GNRs) are predicted to exhibit excellent charge and thermal transport, novel magnetic and spin-polarized edge states, and technologically useful bandgaps, provided that their edge structure and width are controlled with nearly atomic precision. However, producing GNRs with such a high degree of structural fidelity has been a major challenge. We have discovered a scalable technique to synthesize GNRs via the highly anisotropic crystal growth of graphene on Ge(001) during chemical vapor deposition. By tailoring the growth conditions, GNRs with nearly atomically-smooth armchair edges, tunable sub-10 nm widths, and lengths of hundreds of nanometers are synthesized. The GNRs are semiconducting with sizeable bandgaps and display high-performance charge transport at room temperature. By initiating growth from nanoscale seeds, arrays of GNRs with controlled placement and alignment are produced. GNRs are also grown on Si substrates by utilizing epitaxial Ge interlayers. This bottom-up method may provide a route for realizing state-of-the-art technologies based on semiconducting graphene.

**H71.00223: A Novel Opto-mechanical method for Large-scale Production of Boron Nitride Nanosheets in Water**

GAYATHRI H N (Presenter), JYOTI SHAKYA, PHANINDRA SAI, ARINDAM GHOSH, Indian Institute of Science — Hexagonal boron nitride (h-BN) is considered as most promising material for next generation microelectronic and other technologies. It can be easily integrated with other 2D materials such as graphene and molybdenum disulfide (MoS$_2$). The boron nitride nanosheet (BNNs) has lattice constant like that of graphene and a large electrical band gap. Also, it has an atomically smooth surface and large optical phonon modes. These qualities make it applicable as a substrate material for a high-performance graphene electronics and as an ideal nano filler in polymers for many application in polymer industry. To realize such applications at industrial level, the obvious task is to synthesize nanosheets in large scale. Here in we report synthesis of high quality BNNs in large quantities by a novel opto-mechanical method using water as a solvent, without adding any chemical or surfactants. The exfoliated BNNs have been extensively analysed for nanosheet area and thickness by SEM, AFM and Raman spectroscopy.

H71.00224: Mechanical and electrical properties of Ti$_3$C$_2$T$_x$ MXene single flakes

ALEXEY LIPATOV (Presenter), University of Nebraska - Lincoln, MOHAMED ALHABEB, A.J. Drexel Nanomaterials Institute, Drexel University, HAIDONG LU, University of Nebraska - Lincoln, BABAK ANASORI, A.J. Drexel Nanomaterials Institute, Drexel University, ALEXEI GRUVERMAN, University of Nebraska - Lincoln, YURY GOGOTSI, A.J. Drexel Nanomaterials Institute, Drexel University, ALEXANDER SINITSKII, University of Nebraska - Lincoln — Two-dimensional transition metal carbides and nitrides, known as MXenes, are a large class of materials that are finding numerous applications ranging from energy storage and electromagnetic interference shielding to water purification and antibacterial coatings. While bulk applications of MXenes are rapidly developing, their intrinsic physical property characterization through single-flake measurements remains a largely unexplored area of research. Here, we report the elastic properties of monolayers and bilayers of the most important MXene material to date, Ti$_3$C$_2$T$_x$ (T stands for surface termination) measured using nanoindentation with the tip of an atomic force microscope. The effective Young's modulus of a single layer of Ti$_3$C$_2$T$_x$ was found to be 0.33 ± 0.03 TPa, which is the highest among the reported values for solution-processed 2D materials, including graphene oxide. Individual Ti$_3$C$_2$T$_x$ flakes also exhibit a high conductivity of 4600±1100 S/cm and field-effect electron mobility of 2.6±0.7 cm$^2$/Vs. We found that the resistivity of individual flakes is only one order of magnitude lower than the resistivity of multilayer Ti$_3$C$_2$T$_x$ films, which indicates a surprisingly good electron transport through the surface terminations of different flakes, unlike in many other 2D materials.

H71.00225: Two relaxation rates in the in-plane THz conductivity of a clean Sr$_2$RuO$_4$ thin film

YOUCHENG WANG (Presenter), Institute of Quantum Matter, Department of Physics and Astronomy, Johns Hopkins University, HARI NAIR, NATHANIEL SCHREIBER, Department of Materials Science and Engineering, Kavli Institute at Cornell for Nanoscale Science, Cornell University, JACOB RUF, LUDI MIAO, Laboratory of Atomic and Solid State Physics, Department of Physics, Kavli Institute at Cornell for Nanoscale Science, Cornell University, DARRELL SCHLOM, Department of Materials Science and Engineering, Kavli Institute at Cornell for Nanoscale Science, Cornell University, PETER ARMITAGE, Institute of Quantum Matter, Department of Physics and Astronomy, Johns Hopkins University — Understanding the metallic normal state of Sr$_2$RuO$_4$ could help solve puzzles about its unconventional superconducting state. The normal state of Sr$_2$RuO$_4$ is considered a clean Fermi liquid in the low temperature and low frequency limit. Herein we present time domain THz measurements of the optical conductivity of a highly clean, RRR (residual resistivity ratio) ≈ 53 epitaxial thin film, in which we find deviation from Fermi liquid scaling of a simple metal below 3 meV. The complex conductivity can be modeled with two Drude terms, the decay rate of both of which follows $T^2$ dependence. We discuss the physical implications of two conducting channels. We compare the results with our experiments on other metallic ruthenates including SrRuO$_3$ and CaRuO$_3$ with similar RRR.

H71.00226: Synthesis of 2D materials by direct heating of bulk sources*  DAVOUD HEJAZI (Presenter), RENDA TAN, SWASTIK KAR, Northeastern University — Synthesis of high-quality 2D materials usually requires reactors/furnaces of various levels of complexities. A simple method of growing 2D materials or their combined structures (heterostructure, alloys etc.) that is easy to set up and run can accelerate 2D research. We find that single and multilayered 2D materials of various types can be easily fabricated by direct thermal evaporation. This is in stark contrast with conventional vapor-phase techniques that require chemical reactions of precursors and flow of an inert carrier gas so, substantially reducing the cost and complexities. Sources of target nanomaterials are taken in commercial bulk form, reduced to powder, placed on a clean container in close proximity of target substrate in an inert atmosphere, then heated to and held at a range of material-specific high temperatures and durations. The nanomaterials evaporate and deposit directly on the substrate in the form of well-formed crystals. The synthesis methodology is much simpler than the other methods (CVD, MBE, etc.). We present detailed analysis (AFM, optical images, Raman, photoluminescence) of various types of 2D materials/structures possible via direct, mixed, and sequential evaporation of bulk powders.

H71.00227: WITHDRAWN ABSTRACT —

H71.00228: Structural and Physical Properties of “Field-Edited” Iridates*  GANG CAO (Presenter), HENGDI ZHAO, BING HU, NICK PELLATZ, YU ZHANG, DMITRY REZNIK, University of Colorado, Boulder — A great deal of theoretical work addressing exotic states for iridates has thus far met very limited experimental confirmation. The conspicuous discrepancies are due chiefly to the extreme susceptibility to structural distortions inherent in these materials. To fundamentally address this challenge, we have structurally “edited” these materials (borrowing the phrase “genome editing”) via application of magnetic field during single-crystal growth. Our results have demonstrated that the “field-edited” single crystals not only are much less distorted but also exhibit some long-sought phenomena absent in the same materials grown without a magnetic field. We present and discuss these results along with comparisons drawn from other relevant systems.

*This work is supported by NSF via grant DMR 1903888
**H71.00229: Electronic transport in graphene/RuCl$_3$ heterostructures**

(Presenter), EVERARDO MOLINA, Physics and Astronomy, California State University, Long Beach, VIKRAM NAGARAJAN, GILBERT LOPEZ, Physics, University of California, Berkeley, NICHOLAS BREZNAY, Physics, Harvey Mudd College, ROBERT KEALHOFER, Physics, University of California, Berkeley, ISAAC ARRIAGA, DEREK BERGNER, Physics and Astronomy, California State University, Long Beach, JAMES ANALYTIS, Physics, University of California, Berkeley, CLAUDIA OJEDA-ARISTIZABAL, Physics and Astronomy, California State University, Long Beach — Ruthenium Chloride (RuCl$_3$), a spin-orbit assisted Mott insulator, presents exciting physics thanks to spin-orbit entangled moments with interactions that are highly anisotropic, making it a close realization to the Heisenberg-Kitaev model. RuCl$_3$’s highly insulating character limits the accessible experimental techniques to those requiring bulk crystals, such as resonant magnetic scattering, magnetic susceptibility or heat capacity measurements. Here, we design and measure devices that implement few layers of RuCl$_3$ into an electronic device to form a Gr/RuCl$_3$ Van der Waals heterostructure (similar to heterostructures reported recently [1]) with the aim of studying in a quantum coherent regime, signatures of proximity effects between graphene and RuCl$_3$’s magnetic ordered state at low temperatures.

**H71.00230: Qualitative Description of Magnetoelectric Coupling in Multiferroic BTO/CFO Janus Fibers**

SABA ARASH (Presenter), BRYAN CHAVEZ, Department of Physics and Astronomy, University of South Carolina, MATTHEW BAUER, JENNIFER ANDREW, Department of Materials Science & Engineering, University of Florida, THOMAS M CRAWFORD, YANWEN WU, Department of Physics and Astronomy, University of South Carolina — The magnetoelectric coupling dynamics in multi-phase multiferroic materials was investigated in a perovskite-spinel fiber system with Janus structure consisting of ferroelectric barium titanate (BTO) and ferrimagnetic cobalt ferrite (CFO). We observed strong evidence of such coupling from the distinct changes in the second harmonic generation signals under different applied magnetic field orientations. Here, we provide a clear qualitative description of how the electrical polarization of the BTO half is affected by the changes incurred in the magnetization of the CFO half in different groups of fibers. We observed that although the results vary for different fiber ensembles due to the memory of the initial system, the subsequent changes in the fiber system correlate qualitatively and can be understood in a systematic way with our simple dipole model.
H71.00231: Strain-based magneto-electric coupling effect induced orbital reconstruction and near room temperature ferromagnetic insulator state in PbZr$_{0.52}$Ti$_{0.48}$O$_3$/$\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$ heterostructure  CHAO LIU (Presenter), Materials Science and Engineering, National University of Singapore — Multiferroic heterostructures attracts much attention due to fascinating potential applications in electric field control of magnetism and abundant physics significance. However, more and more fascinating phenomenon appearing near ferromagnetic/ferroelectric interface requires deeper investigation on this interface and the related coupling mechanism. Here, a near room temperature ferromagnetic insulator state in PbZr$_{0.52}$Ti$_{0.48}$O$_3$/$\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$ heterostructures was reported by varying PbZr$_{0.52}$Ti$_{0.48}$O$_3$ thickness. Abnormal enlarged c/a ratio in La$_{0.67}$Sr$_{0.33}$MnO$_3$ by strain-based coupling effects, which lead to d$_{3z^2-r^2}$ orbital preferable occupancy and narrower e$_g$ bandwidth, was regarded as the dominant reason while valence change induced by charge-based coupling effects could be limited responsible considering short screening length. This work paves a deeper understanding of strain-based coupling effects across ferromagnetic/ferroelectric interface and enrich physics content in La$_{1-x}\text{Sr}_x\text{MnO}_3$ based electron strong correlated system.

H71.00232: Tunneling Transport in Gapped Graphene through a Bias-Tunable Potential Barrier* DANHONG HUANG (Presenter), Space Vehicles Directorate, Air Force Research Lab - Kirtland, FARHANA ANWAR, Center for High Technology Materials, University of New Mexico, ANDRII IUROV, Department of Physics and Computer Science, Medgar Evers College of City University of New York, GODFREY GUMBS, Department of Physics and Astronomy, Hunter College of the City University of New York, ASHWANI SHARMA, Space Vehicles Directorate, Air Force Research Lab - Kirtland — We have investigated electron tunneling and transport properties for graphene through a non-square barrier with a finite slop in the potential profile. We have developed a new methodology based on the finite-difference solution of the scattering equations for a Dirac electron, and have also built a perturbation theory for the electron transmission for the case with a small slope. Both gapped and gapless graphene materials have been considered in our calculations. All these predicted properties are expected to have the highest importance for novel electronic and optical devices.

*DH would like to acknowledge the financial supports from the Air Force Office of Scientific Research (AFOSR) and the Laboratory University Collaboration Initiative (LUCI) program.
H71.00233: Gauging electronic transport in Sodium Iridate and Vanadium Triiodide thin crystals through graphene heterostructures*  EVERARDO MOLINA (Presenter), SARA QUBBAJ, Physics and Astronomy, California State University, Long Beach, VIKRAM NAGARAJAN, Physics, University of California, Berkeley, TAI KONG, Chemistry, Pinceton University, GILBERT LOPEZ, Physics, University of California, Berkeley, NICHOLAS BREZNAY, Physics, Harvey Mudd College, ROBERT KEALHOFER, Physics, University of California, Berkeley, DEREK BERGNER, ISAAC ARRIAGA, Physics and Astronomy, California State University, Long Beach, ROBERT J. CAVA, Chemistry, Pinceton University, JAMES ANALYTIS, Physics, University of California, Berkeley, CLAUDIA OJEDA-ARISTIZABAL, Physics and Astronomy, California State University, Long Beach - Sodium Iridate (Na$_2$IrO$_3$) presents exciting ground states thanks to the combination of electronic correlations, spin-orbit coupling, crystal field effects and a honeycomb arrangement of the iridium ions. Vandium triiodide (V$_3$I) on the other hand, constitutes a promising candidate for 2-D magnetism. Due to the highly insulating behavior of these materials, little progress has been made in terms of transport measurements. Here we explore an indirect transport measurement of thin exfoliated Na$_2$IrO$_3$ and V$_3$I crystals through a graphene heterostructure.

*This project was funded by the Department of Energy award number DE-SC0018154

H71.00234: Asymmetry strain induced superdomain structures in (101)-oriented Pb(Zr$_{0.2}$Ti$_{0.8}$)O$_3$ and PbTiO$_3$  SHENG-ZHU HO (Presenter), MENG-XUN XIE, YU-CHEN LIU, YU-HUAI LI, JAN-CHI YANG, YI-CHUN CHEN, Natl Cheng Kung Univ - Ferroelectric materials in room temperature have attracted great scientific and technological interests due to its huge potential for applications in nonvolatile memory devices. Lead zirconate titanate (Pb(Zr$_x$Ti$_{1-x}$)O$_3$, PZT) compounds, with remarkable ferroelectricity, is one of the most commonly studied system. Abundant previous researches have shown that ferroelectric domain structures of the PZT system would depend on the orientation of epitaxial substrate due to the strain effect. In this study, we investigated the domain structures of (101)-orientated tetragonal Pb(Zr$_{0.2}$Ti$_{0.8}$)O$_3$ (PZT) and PbTiO$_3$ (PTO) epitaxial films grown on cubic SrTiO$_3$ (110) substrates by vector piezoresponse force microscopy (vector-PFM). Interestingly, we observe superdomains with particular spontaneous polarizations on both PZT and PTO films which are under asymmetry strains from the substrate. However, comparing with those of (101)-orientated PTO, (101)-orientated PZT has more fine structures within one superdomain period, which are with polarization rotations along phi-direction observed by vector-PFM. As the result, we could further confirm the strain effect break the in-plane symmetry of the PZT and PTO films and and lead to the superdomain structures.
**H71.00235: Study of structural, electromagnetic and magnetoelectric properties of multiferroic composites**

BABLU CHANDRA DAS (Presenter), MD. FEROZ ALAM KHAN, M. A. MATIN, A.K.M. AKTHER HOSSAIN, Department of Physics, Bangladesh University of Engineering and Technology, Dhaka-1000, Bangladesh — Abstract

The composition $(1-x)\text{Ba}_{0.985}\text{Ca}_{0.015}\text{Zr}_{0.10}\text{Ti}_{0.90}\text{O}_3 + (x)\text{Ni}_{0.48}\text{Cu}_{0.12}\text{Zn}_{0.40}\text{Gd}_{0.04}\text{Fe}_{1.96}\text{O}_4$ (where $x = 0.0, 0.2, 0.4, 0.6$ and $1.0$) was prepared using the conventional solid state reaction method. The X-Ray diffraction analysis confirmed the coexistence of the two phases of the present research. Microstructural and surface morphology were studied by Field Emission Scanning Electron Microscopy (FESEM). Magnetic properties e.g. permeability, magnetic loss and quality factor have been calculated as a function of frequency. The dielectric properties such as dielectric constant and dielectric loss were measured as a function of frequency and temperature at room temperature. $M - H$ hysteresis loops and $P - E$ hysteresis loops confirm the ferromagnetic and ferroelectric nature of the composite samples. Variation of the ME coefficient ($\alpha_{ME}$) with the dc magnetic field was also measured for the multiferroic composite samples.

*This research was funded by CASR, Bangladesh University of Engineering and Technology (BUET).*

**H71.00236: Thermally Induced Metastable Inter-Ferroelectric Phase Switching in Mechanically Biased Single Crystal Relaxor Ferroelectrics**

PETER FINKEL (Presenter), United States Naval Research Laboratory, STEPHAN M YOUNG, UMKC, SAMUEL E LOFLAND, Rowan University, MARGO STARUCH, United States Naval Research Laboratory — In this work we examine a thermally induced metastable phase transition in mechanically biased piezoelectric $[\text{Pb(In}_{1/2}\text{Nb}_{1/2})\text{O}_3]_{0.24}[\text{Pb(Mg}_{1/3}\text{Nb}_{2/3})\text{O}_3]_{0.46}[\text{PbTiO}_3]_{0.32}$ domain-engineered single crystals. Our results show a purely thermally-driven first order ferroelectric rhombohedral-to-orthorhombic phase transition accompanied by a large, sharp discontinuity in strain while the piezocrystal is held under mechanical compressive bias stress and variable electric field bias. We demonstrate this transition can be cycled repeatedly with a small thermal hysteresis ($< 3^\circ$C) under zero applied electric field with dynamic reversible strain jump of $\sim 0.25 \%$. Moreover, we show that the thermally driven phase switching behavior can be tuned by varying the bias stress and/or electric field, illustrating the path for establishing effective control parameters and conditions for potential future applications such as actuators, thermoelectric transducers and sensors.
Colossal Dielectric Constant Achieved via Acceptor-Donor doped ZnO Ceramic

DONG HUANG (Presenter), CHI-CHUNG LING, The University of Hong Kong — Materials having colossal dielectric constant (CDC) and low loss, with good frequency stability is crucial for device miniaturization and high-energy density storage application. Hu et al. recently reported a temperature and frequency independent CDC with a low dielectric loss in acceptor-donor co-doped TiO$_2$. The CDC is postulated to be originated from electron-pinned defect dipoles which is the acceptor-donor defect complex, though the detail mechanism and experimental evidence are lacking.

Li-Al co-doped ZnO, Zn$_{0.99}$(Li$_{0.1}$, Al$_{0.2}$)$_{0.033}$, ceramic exhibits CDC with good frequency stability, which have a dielectric constant $\sim$10$^4$ at 1 kHz. Impedance spectroscopy shows that the CDC phenomenon is not associated with the internal barrier capacitance (IBLC) effect. M"(f) spectrum obtained from electric modulus analysis reveals two relaxation processes P1 and P2. Frequency dependent ac conductivity data can be well fitted by the Correlated Barrier Hopping (CBH) model, showing that the CDC would be originated from the thermally activated electron hopping between two neighboring acceptor-donor defect sites over their Coulombic barrier. A simple model involving these acceptor-donor defect complex dipoles and the Cole-Davidson distribution of relaxation time can explain the CDC phenomenon.

WITHDRAWN ABSTRACT

The Effect of Semiconductor Nanostructures on the Performance of Nanometer-Thick Parallel Plate Capacitors*

MASOUD KAVEH (Presenter), NIKOLAS ROESKE, Physics and Astronomy, James Madison University, FAZEL BANIASADI, CHENGGANG TAO, Department of Physics, Virginia Tech, HOE TAN, MYKHAYLO LYSEVYCH, CHENNUPATI JAGADISH, Department of Electronic Materials Engineering, Research School of Physics and Engineering, Australian National University — We fabricate nanometer thick, parallel plate capacitors which have semiconductor nanostructures as their dielectric spacers and investigate their capacitance as a function of geometry and the type and thickness of spacer and metal plates. Selected semiconductors are SrTiO$_3$ nano-powder and GaAs and Si nanowires (NW) which have relatively high dielectric constants. 30 nm and 60 nm thick Au plates are fabricated on both solid glass and flexible poly(methyl methacrylate) substrate using an electron beam deposition system. The vertically aligned 50 nm diameter GaAs NWs were grown using the Au catalyzed vapor-liquid-solid method. The Si NWs are randomly oriented with an average diameter of 70 nm. The SrTiO$_3$ nano-particles are cubical with a width of around 30 nm. The reference sample, Au plates with air as dielectric, reveal capacitance in the pico-Farad order. However, capacitor structures with semiconductor dielectrics show an enhancement of the total capacitance, mainly explained by the semiconductor spacer weakening the effective internal electric field. Photoluminescence measurements on the semiconductors adjacent to Au plates also show an energy transfer from semiconductor excitons to plasmon oscillations in the Au plates.

NSF grant # 9624436

H71.00241: The strong nonlinearity optical calculation of 3D Dirac semimetals.** TIANNING ZHANG (Presenter), YEE SIN ANG, Singapore University of Technology and Design — The optical nonlinearity of novel Dirac materials, such as graphene, have been extensively studied theoretically and experimentally in recent years. Due to the exceptionally strong light-matter interactions, Dirac material is promising in revolutionizing the functionality of photonic and optoelectronic device technology. In this work, we study the nonlinear optical response generated by the massless Dirac quasiparticles residing around the topologically-protected Dirac nodal points in three-dimensional (3D) Dirac topological semimetals in the terahertz frequency regime. Analytical expressions of third-order interband nonlinear optical conductivities are obtained based on semiclassical Boltzmann equation and quantum mechanical Floquet theory. Using Cd$_3$As$_2$ as an example, we demonstrate that the optical nonlinearity of 3D Dirac semimetal at terahertz frequency is comparable to that of the two-dimensional Dirac fermions in graphene. Importantly, the additional degree of freedom of 3D Dirac semimetal shall offer additional optical device design flexibility not found in atomically-thin graphene.

H71.00242: "Origin of Exceptional Magneto-resistance in Weyl Semimetal TaSb$_2$"* PAWAN KUMAR (Presenter), School Of Physical Sciences, Jawaharlal Nehru University New Delhi India, SUDESH SUDESH, Department of Physics, Banasthali University, Niwai Tonk Rajasthan India, GANESH GURJAR, SATYABRATA PATNAIK, School Of Physical Sciences, Jawaharlal Nehru University New Delhi India — We study magneto-transport properties in single crystals of TaSb$_2$, which is a topological semimetal. In the presence of magnetic field, the electrical resistivity shows onset of insulating behaviour followed by a plateau at low temperature. Such resistivity saturation is generally assigned to topological surface states but we find that aspects of extremely large magneto resistance and resistivity plateau are well accounted by classical Kohler's scaling. In addition, magneto-resistance in TaSb$_2$ shows non-saturating field dependence. Evidence for anomalous Chiral transport is provided with observation of negative longitudinal magneto-resistance. Shubnikov-de Haas oscillation data reveal two dominating frequencies, 201 T and 455 T. At low temperature, the field dependence of Hall resistivity shows non-linear behaviour that indicates the presence of two types of charge carriers in consonance with reported electronic band structure. Analysis of Hall resistivity implies extremely high electron mobility.

*P. Kumar, Sudesh and G. Gurjar acknowledges UGC-India for fellowship support. Authors are thankful to AIRF(JNU INDIA) for the access to PPMS and TEM facilities. S. Patnaik thanks SERB DST INDIA for the project EMR/2016/003998/PHY.

H71.00243: Ultrahigh conductivity in Weyl semimetal NbAs nanobelts* CHENG ZHANG, XIANGYU CAO (Presenter), FAXIAN XIU, Department of Physics, Fudan University — In two-dimensional (2D) systems, high mobility is typically achieved in low-carrier-density semiconductors and semimetals. Here, we discover that the nanobelts of Weyl semimetal NbAs maintain a high mobility even in the presence of a high sheet carrier density. We develop a growth scheme to synthesize single crystalline NbAs nanobelts with tunable Fermi levels. Owing to a large surface-to-bulk ratio, we argue that a 2D surface state gives rise to the high sheet carrier density, even though the bulk Fermi level is located near the Weyl nodes. A surface sheet conductance up to 5–100 S per is realized, exceeding that of conventional 2D electron gases, quasi-2D metal films, and topological insulator surface states. Corroborated by theory, we attribute the origin of the ultrahigh conductance to the disorder-tolerant Fermi arcs. The evidenced low-dissipation property of Fermi arcs has implications for both fundamental study and potential electronic applications.

**H71.00244: Suppression of magnetism and Seebeck effect in Na$_{0.875}$CoO$_2$ induced by Sb$_{Co}$ dopants**  MOHAMMED H. N. ASSADI, University of New South Wales, MARCO FRONZI (Presenter), IRCRE, Xi’an Jiaotong University, PAOLO MELE, Shibaura Institute of Technology — We examined the electronic properties of Sb-doped Na$_{0.785}$CoO$_2$ using density functional calculations based on GGA+U formalism. We demonstrated that Sb dopants were the most stable when replacing Co ions within the complex Na$_{0.875}$CoO$_2$ lattice structure. We also showed that the Sb$_{Co}$ dopants adopted the +5 oxidation introducing two electrons into the host Na$_{0.875}$CoO$_2$ compound. The newly introduced electrons recombined with holes that were borne on Co$^{4+}$ sites that had been created by sodium vacancies. The elimination of Co$^{4+}$ species, in turn, rendered Na$_{0.875}$(Co$_{0.9375}$Sb$_{0.0625}$)O$_2$ non-magnetic and diminished compound’s thermoelectric effect. Furthermore, The Sb$_{Co}$ dopants tended to aggregate with the Na vacancies keeping a minimum distance. Conclusions drawn here can be generalized to other highly oxidized dopants in Na$_x$CoO$_2$ that replace a Co.

**H71.00245: Temperature influence in the broadening parameter of photoreflectance spectras on GaAs doped with Ge and Sn as aged samples**  SAMUEL ZAMBRANO (Presenter), University of Magdalena, University of Guajira, GERARDO FONTHAL, Doctoral Program in Physical Sciences, University of Quindio, JOSE SIERRA, University of Magdalena, JOHN PRIAS, Doctoral Program in Physical Sciences, University of Quindio — Aged samples of GaAs doped with Ge and Sn growth by liquid phase epitaxy, show temperature influence in the broadening parameter of the photoreflectance spectras domined mainly by the photon-defects interactions. The samples were characterized via Raman spectroscopy, X-ray diffraction technique and scanning electron microscopy. The photoreflectance spectras were taken by varying temperatures from 20 to 300 K. Optical measurements suggest that increase temperature and increases broadening parameter, exhibiting changes in the photon-defects interactions, possibly attributed to increase in aging defects.

**H71.00246: Investigation of the obscure spin state of Ti-doped CdSe**

JOHN DIMUNA (Presenter), TUCKER BOYETT, Univ of North Florida, ANANT K RAMDAS, IREK MIOTKOWSKI, Purdue University, THOMAS PEKAREK, JASON HARALDSEN, Univ of North Florida — Using computational and experimental techniques, we examine the nature of the 2+ oxidation state of Ti-doped CdSe. Through stoichiometry and magnetization measurements, the weakly-doped material of Cd$_{1-x}$Ti$_x$Se ($x = 0.0043$) shows the presence of a robust spin-1 magnetic state of Ti, which is indicative of a 2+ oxidation state. Given the nature of the Ti$^{2+}$ state, we investigate the electronic and magnetic states with density functional theory for a supercell of CdSe with an ultra-low concentration of Ti. We find that reproducing the magnetic moment of spin-1 requires an onsite potential of 4-6 eV must be included. Furthermore, the electronic structure and density of states show the presence of a Ti-$d$ impurity band above the Fermi level and a weakly metallic state for a $U = 0$ eV. However, the evolution of the electronic properties as a function of the Hubbard U shows that the Ti-$d$ drop below the Fermi around 4 eV with the onset of a semiconducting state. The impurity then mixes with the lower valence bands and produces the 2+ state for the Ti atom.

**H71.00247: Understanding the spin-glass state through the magnetic properties of Mn-doped ZnTe**

ALEXANDRIA R ALCANTARA (Presenter), DINA MATEV, Univ of North Florida, ANANT K RAMDAS, IREK MIOTKOWSKI, Purdue University, THOMAS PEKAREK, JASON HARALDSEN, Univ of North Florida — To understand the spin-glass state of diluted magnetic semiconductors, we have examined the magnetic properties of Zn$_{1-x}$Mn$_x$Te using density functional theory and magnetization measurements. Utilizing the generalized gradient approximation, we investigate the dependence of the Hubbard onsite potential on the magnetization and electronic structure. We find that the ground state magnetic preference is antiferromagnetic and that the onsite potential is needed to harden the magnetic moment of $S = 5/2$. Furthermore, the system is clearly semi-conducting, which suggests that the spin-glass nature of the compound is produced through the magnetic exchange interactions through the $p$- and $d$-orbital hybridization.

H71.00248: (Si)GeSn Semiconductors for integrated optoelectronics and quantum electronics

SIMONE ASSALI (Presenter), AASHISH KUMAR, MAHMOUD ATALLA, SALIM ABDI, SAMIK MUKHERJEE, ANIS ATTIAOUI, OUSSAMA MOUTANABBIR, Ecole Polytechnique de Montreal — Si-compatible photonic and opto-electronic devices operating at mid-infrared wavelengths can now be fabricated using Sn-containing group IV semiconductor (Si)GeSn alloys, directly grown on a Si substrate. The possibility to independently engineer strain and composition in this new class of semiconductors allows for a high degree of tunability of band structure and lattice parameter of the material, thus enabling a variety of multi-layer heterostructures and low-dimensional systems.

In this presentation, the recent progress in the epitaxial growth of metastable (Si)GeSn semiconductors in a CVD reactor will be discussed. The effect of the growth parameters on the structural and opto-electronic properties will be highlighted, ranging from the macroscopic scale down to the atomic-level, hence providing a deeper understanding of the fundamental properties of this material system. The relevance of (Si)GeSn semiconductors for Si-compatible mid-infrared opto-electronics will be discussed by correlating the material properties (crystalline quality, compositional profile, point defects, dopants incorporation and active carrier concentration) with the opto-electronic properties of p-i-n MIR photodetectors.

H71.00249: Long-lived modulation of plasmonic absorption by remote thermal injection*

JOHN TOMKO (Presenter), Univ of Virginia, EVAN RUNNERSTROM, North Carolina State University, YI-SIANG WANG, University of Southern California, JOSHUA NOLEN, Vanderbilt University, DAVID OLSON, Univ of Virginia, KYLE KELLEY, ANGELA CLERI, JOSH NORDLANDER, Pennsylvania State University, JOSHUA D CALDWELL, Vanderbilt University, OLEG PREZHDHO, University of Southern California, JON-PAUL MARIA, Pennsylvania State University, PATRICK HOPKINS, Univ of Virginia — Light interactions capable of inducing charge and energy transfer across interfaces are the fundamental basis for a multitude of technologies, including photocatalysis, energy harvesting, and photodetection. One of the more common mechanisms associated with these processes relies on injection of the charge carrier itself. In this work, we elucidate upon a novel means of of electronic energy injection that can be accessed by relying on non-equilibrium dynamics achievable at metal-semiconductor interfaces that has yet to be realized. This remote thermal injection (RTI) process is demonstrated through an ultrafast pump-probe technique that relies on monitoring the optical properties of a mid-infrared epsilon-near-zero cavity following optical excitation of a remote contact, providing a highly sensitive probe into the spatial variations of electron density and energy relaxation mechanisms in the heterostructure. These results are further supported via ab initio density functional theory (DFT) simulations.

H71.00250: *Investigation of Exciton-Phonon Coupling in Cesium Lead Bromide Perovskite Nanosheets with photoluminescence*  
Xiangzhou Lao (Presenter), Shijie Xu, The University of Hong Kong — Variable-temperature photoluminescence (PL) spectra of cesium lead bromide (CsPbBr$_3$) nanosheets were measured in a low temperature range of 5 to 40 K. In this interested low temperature range the measured PL spectra exhibit a main zero-phonon peak and its longitudinal-optical (LO) phonon sideband, and are quantitatively simulated using the multimode Brownian oscillator (MBO) model. Good agreement between theory and experiment enables us to determine several key parameters characterizing the exciton–phonon coupling, including the dimensionless Huang-Rhys factor $S$ accounting for the exciton-LO phonon coupling strength and the damping constant $\gamma$ for the phonon bath (quasi-continuous acoustic phonons) dissipation. It is found that Huang-Rhys factor $S$ peculiarly tends to diminish upon increasing the temperature, suggesting weakened exciton-LO phonon coupling in the interested low-temperature range. However, as often observed in solids, the damping constant $\gamma$ in the nanosheets increases almost linearly with the rise of temperature. This study may shed some light on the complex exciton-phonon scattering mechanisms in solids.

H71.00251: *Carrier Multiplication in Quasi-1D Nanosystems: A Time-Dependent Density Functional Theory Study*  
Junhyeok Bang (Presenter), Chungbuk Natl Univ — Carrier multiplication (CM) is a fundamental process in the electronic excited state, which generates multi-excitons from a single-photon absorption. CM has been intensively investigated for photovoltaic applications, because it can improve optoelectronic devices efficiency. However, CM is rarely witnessed in conventional semiconductors, calling for an unconventional material enhancing the CM. Here, using real-time time-dependent density functional theory, we show that CM occurs in quasi-one-dimensional (1D) nanosystems derived from 2-dimensional van der Waals materials. The origin of CM in quasi-1D, i.e., releasing the constraints of the CM process, are different from that in 0D nanosystems, i.e., phonon bottleneck. The results provide the way to control the excited carrier dynamics and CM in nanosystems.

H71.00252: WITHDRAWN ABSTRACT
H71.00253: Two-Exciton states in Cyanine Dimers on DNA Scaffolds  PAUL CUNNINGHAM (Presenter), SEBASTIAN A. DIAS, YOUNG C. KIM, DIVITA MATHUR, United States Naval Research Laboratory, DONALD L KELLIS, BERNARD YURKE, RYAN D PENSACK, WILLIAM B KNOWLTON, Boise State University, IGOR L. MEDINTZ, JOSEPH S. MELINGER, United States Naval Research Laboratory — The control of intermolecular coupling is a pathway towards achieving highly efficient energy transport in artificial light-harvesting networks. Similar requirements are also needed for the design of molecular wires and logic structures within the field of molecular excitonics. Here we report on the creation of cyanine dye homodimers on DNA scaffolds. The DNA provides a backbone to precisely control dye placement through covalent attachment and thereby the coupling strength, allowing the absorption and emission properties of the resulting dimers to be tailored. Through this strategy, we are able to realize delocalized one- and two-exciton states, the later of which is a first for a DNA-scaffolded system. Such multi-exciton states hold promise for entangled photon emission and molecular logic gates. Both the one- and two-exciton states are well described by molecular exciton theory when electron-vibrational coupling is accounted for. We also address the impact of molecular motion on the dynamics of these states, and identify a path towards greater control of these properties.

H71.00254: Exact Steady-state Solution of Electron Transport Through a Quantum System Coupled with Dissipative Electrodes*  TSE-MIN CHIANG (Presenter), LIANG-YAN HSU, Academia Sinica — In the framework of the Lindblad quantum master equation, we develop a theory which allows us to describe electron transport through a molecular junction coupled with dissipative electrodes. We generalize the theory of coherent quantum transport and include the electronic dissipation in electrodes. Moreover, we derive an exact solution of steady-state current and analyze the asymptotic behavior in the different limits of electronic dissipation. Furthermore, we obtain a Landauer-type formula and show that this formula can be reduced to the original Landauer formula in the condition of zero dissipation rate.

ANASTASIA SPIRIDONOVA (Presenter), The Graduate Center, City University of New York — Monolayer transition-metal dichalcogenides (TMDC) such as MoS$_2$, MoSe$_2$, WS$_2$ and Se$_2$ host a series of exciton Rydberg states denoted by the principal quantum number $n = 1, 2, 3$, etc. We study the 1$s$–2$s$ exciton Rydberg states in TMDC monolayers encapsulated by hexagonal boron nitride (hBN) under the action of a magnetic field. The exciton Rydberg states exhibit similar Zeeman shifts but distinct diamagnetic shifts from each other. Excitons in the magnetic field are described in the framework of the potential model. We have used the Keldysh potential to calculate the energies of exciton Rydberg states in hBN-encapsulated monolayers of MoS$_2$, MoSe$_2$, WS$_2$, and WSe$_2$ under varying magnetic field. Our calculations use as inputs the effective masses of electron and hole obtained in the framework of the density functional theory. The binding energies of exciton are calculated using the first-order perturbation theory, which gives good approximation only in the low magnetic field. These binding energies are comparable to experimental measurements. Our results are consistent with the other theoretical predictions.

TUOMAS ROSSI (Presenter), PAUL ERHART, Department of Physics, Chalmers University of Technology, MIKAEL KUISMA, Department of Chemistry, University of Jyväskylä — Metal nanoparticles absorb light much more than their physical size would suggest due to the excitation of a localized surface plasmon resonance. After its excitation, the plasmon resonance decays into high-energy electrons and holes, which, combined with the large absorption cross section, make metal nanoparticles attractive hot-carrier generators for photocatalysis. In this presentation, we describe the femtosecond dynamics of localized surface plasmons in noble metal nanoparticles by using time-dependent density-functional theory (TDDFT). We track the plasmon formation and decay into hot carriers in terms of contributing electron-hole transitions [1,2]. By analyzing the resulting hot-carrier distributions down to atomic-scale detail, we shed light on the hot-carrier generation in catalytically-relevant edge and corner sites of nanoparticles [2].

H71.00257: ABCs of strong exciton–plasmon coupling in 2D TMDCs*  AARON ROSE (Presenter), JEREMY R. DUNKLIN, LUCY METZROTH, HANYU ZHANG, ELISA M MILLER, JAO VAN DE LAGEMAAT, National Renewable Energy Laboratory — We present experimental details of strong exciton–plasmon coupling in 2D MoS$_2$ at the A-, B-, and C-excitons at room temperature. In one experiment, we show plasmon-mediated coherent hybridization of the A- and B-excitons. Rabi splitting of $\sim 70$ meV in $k$-space at each exciton is also shown. The observation of coherent coupling between different exciton energy levels in a valley-polarized material suggests the possibility of valleytronic quantum information transport and/or spin entanglement.

In another experiment we show giant Rabi splitting of 244 meV at the C-exciton, in $k$-space. This corresponds to 9.5% of the transition energy and approaches the ultrastrong coupling regime. We discuss the role the TMDC band structure plays in this large coupling and unique features of the C-exciton.

The band modification that materials experience under strong coupling can be useful for modifying chemical reaction pathways and rates. We discuss experimental design considerations and show results of strong coupling in aqueous electrolyte.

The experimental work is backed up by electromagnetic transfer matrix and coupled oscillator models.
